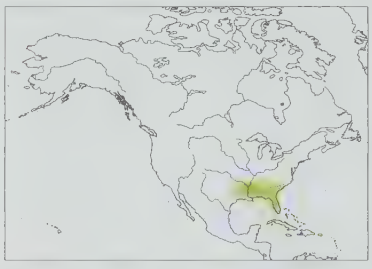
Breeding. Breeds generally during summer, Jun to early Oct, depending on rains, beginning usually after a day of monsoon rainfall exceeding 14 mm, rarely nests in spring; sometimes double-brooded. Monogamous; pair-bond may be maintained throughout year. Nest constructed by female, taking 3–4 days to complete work, a large and deep cup made from grasses, lined with finer "cholla grass" and hair, usually placed 15 cm to 2 m (commonly c. 0·5 m) above ground in spiny tree or cholla cactus, easily found. Clutch 2–5 eggs, most commonly 3 after summer rains, 2–4 after spring rains, whitish to pale greenish and unspotted; incubation by female, period 11 days; chicks fed by both adults, nestling period 8–9 days. Nests sometimes parasitized by Brown-headed Cowbird (*Molothrus ater*), but breeding period overlaps little with that of latter.
Movements. Resident; some short-distance movements may occur when food limited. After very wet years, where breeding success high, extends range to areas within 100 km of regular breeding sites, this attributed to post-breeding dispersal by young.
Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Often common or very common in appropriate habitat. Global population estimated at c. 74,000 individuals. In N of range, numbers fluctuate according to amount of rainfall. In many areas, habitat degraded as a consequence of overgrazing and urbanization.
Bibliography. Anderson (1965), Anon. (1998), Armani (1985), Austin & Ricklefs (1977), Binford (1989), Deviche *et al.* (2006), Hellmayr (1938), Howell & Webb (1995), Lebbin *et al.* (2010), Lowther, Groschupf & Russell (1999), Moore (1946), Phillips (1951), Pitelka (1951), Russell & Monson (1998), Small, T.W. *et al.* (2007), Storer (1955), Wolf (1977).

99. Cassin's Sparrow

Peucaea cassinii

French: Bruant de Cassin **German**: Cassinammer **Spanish**: Chingolo de Cassin

Taxonomy. *Zonotrichia cassinii* Woodhouse, 1852, near San Antonio, Texas, USA.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Closely related to *P. aestivalis* and *P. botterii*, all having aerial song displays; molecular analyses suggest that this group is close to a clade consisting of *P. ruficauda*, *P. humeralis*, *P. mystacalis*, *P. sumichrasti* and *P. carpalis*. Monotypic.
Distribution. Breeds from C & S USA (SW South Dakota, C Wyoming, E & C Colorado E to WC Kansas, and C Oklahoma, S to SW New Mexico, and S Texas) and N Mexico (S to N Chihuahua, S Coahuila, Zacatecas, San Luis Potosí, and SE Tamaulipas). Non-breeding SW USA (SE Arizona, SW New Mexico, W Texas, possibly also E Nevada) S in Mexico to S Sinaloa, San Luis Potosí, N Nuevo León and N Tamaulipas, rarely to Guanajuato.



Descriptive notes. 13–15 cm; 14–23·5 g. A medium-sized sparrow with a relatively small bill and rounded tail. Head is streaked with grey and dark brown, indistinct supercilium buff and grey, faint brown moustachial stripe, and thin dark malar stripe; feathers of mantle and scapulars brown, with darker brown markings and paler grey to buff fringes, uppertail-coverts with brown spots; tail dark brown, central feather pair with dark shaft streak, outer three pairs with whitish tips, outermost also edged whitish (pale areas indistinct in worn plumage); upperwing blackish-brown, feathers edged pale grey, median and greater coverts also tipped pale buff (forming indistinct wingbars); chin, throat and breast grey; flanks grey, with black streaks posteriorly, belly whitish, undertail-coverts sometimes buffy; iris dark brown; bill largely dark brownish-grey, pale bluish-grey on cutting edges and all of lower mandible; legs dull pinkish. Sexes similar. Juvenile is similar to adult, but back brown, feathers with buffy tips and darker brown central streaks, greater coverts edged with white, and light streaking on breast and throat. Voice. Song, often in flight, also at night, a clear, usually descending sweet liquid trill, followed by 2 notes, second higher than first, also preceded by 2 soft notes (seldom heard), "ti ti tzeeeeeeeeeee tay tay". Also a chitter flight song, a rapid series of chipping notes. Call "chip" when around young, or alarmed; also a soft "sip".
Habitat. Arid grassland with scattered bushes, desert scrub and tropical thorn-scrub, with grass, and in open farmland in tropical deciduous forest. Sea-level to 2150 m.
Food and Feeding. During nesting period feeds principally on insects, especially grasshoppers (Orthoptera), Lepidoptera larvae, bugs (Hemiptera), ants, wasps and bees (Hymenoptera), and occasionally beetles (Coleoptera), as well as spiders (Araneae) and snails (Gastropoda); also seeds. Forages mostly on or near ground and low in vegetation. Sometimes in small groups outside breeding season.
Breeding. Timing not well understood: males start to sing after arrival in spring (in Kansas in late Apr); in SW New Mexico and SE Arizona (where rarely breeds in spring) also sings in late summer after monsoon rains (late Jul and Aug), but not known if these birds are breeding; it has been suggested that birds failing to breed early in season in Great Plains may move SW and breed in Aug, but no direct evidence; possibly double-brooded, with early brood in plains, and later one in SW. Apparently monogamous. In song flight, male sings as it rises up to c. 6 m, sets its wings, and floats back to a low bush, perhaps 10 m away. Nest built by female, a cup of dry grasses and stems, lined with rootlets, finer grasses and horsehair, placed on ground or within 20 cm of it in shrub or bunchgrass. Clutch 3–5 eggs, most commonly 3–4 eggs, white and unspotted; incubation by female, period 11 days; chicks fed by both parents, nestling period 7–9 days. Nests parasitized very uncommonly by Brown-headed Cowbird (*Molothrus ater*).
Movements. Present all year in S part of range, but ringing studies indicate that breeding and non-breeding populations there are different. N populations, S to C Texas, appear to be migratory; present only in winter in C Mexico, indicating some N–S movement. Appears to be somewhat nomadic; breeds in desert areas when rainfall levels and grass heights adequate, perhaps moving to entirely different area in following year; has been hypothesized that this species may breed in N part of range, then migrate S to deserts of SW USA and breed again during monsoon. More study needed to elucidate exact migratory strategy. In spring, arrives in Kansas, Oklahoma and N Texas from late Mar to late Apr, main arrival in mid-Apr; birds wintering in Arizona leave between late Apr and early May. In autumn, most movement out of N breeding grounds in middle to late Sept, rarely some remaining into Nov. Vagrant, largely in spring, to NE as far as SE Canada (S Ontario, Nova Scotia) and NE USA (Maine); vagrant also on California coast.
Status and Conservation. Not globally threatened. Locally common or very common in appropriate habitat. Breeds in some years, rarely, in S California E of the Sierra. Populations in Great Plains may be declining, but evidence on this not clear. Breeds more commonly in native grasses than in areas planted with exotic species. Near urban areas, much suitable habitat has been destroyed by urban development.
Bibliography. Anon. (1998), Armani (1985), Beadle & Rising (2002), Binford (1989), Bowers & Dunning (1985), Burke (2001), Davis (1963), Dorn & Dorn (1995), Dunning, Bowers *et al.* (1999), Hellmayr (1938), Howell & Webb (1995), Hubbard (1977), Hubbard & Crossin (1974), Kingery & Julian (1971), Mason (1992), Miller *et al.* (1957), Phillips (1944), Rising & Beadle (1996), Russell & Monson (1998), Savage & Dick (1969), Schnase *et al.* (1991), Storer (1955), Wolf (1977).

100. Bachman's Sparrow

Peucaea aestivalis

French: Bruant des pinèdes **German**: Bachmanammer **Spanish**: Chingolo de Bachman
Other common names: Pine Woods Sparrow

Taxonomy. *Fringilla aestivalis* M. H. C. Lichtenstein, 1823, Georgia, USA.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Closely related to *P. cassinii* and *P. botterii*, all having aerial song displays; molecular analyses suggest that this group is close to a clade consisting of *P. ruficauda*, *P. humeralis*, *P. mystacalis*, *P. sumichrasti* and *P. carpalis*. Geographical variation largely clinal, and races weakly differentiated. Three subspecies recognized.
Subspecies and Distribution.
P. a. illinoensis Ridgway, 1879 – breeds in EC USA from Arkansas, SE Oklahoma and E Texas E to S Kentucky and S Louisiana; non-breeding E Texas and along Gulf Coast E to Mississippi R.
P. a. bachmani (Audubon, 1833) – breeds SE USA from S Kentucky and S Virginia S to S Mississippi, S Alabama and S Georgia; non-breeding in S of range (from Mississippi E to C North Carolina) S to Gulf Coast and C Florida.
P. a. aestivalis (M. H. C. Lichtenstein, 1823) – breeds from E South Carolina and E Georgia S to S Florida; non-breeding S Georgia and Florida.

Descriptive notes. 12–16 cm; 18·4–22·6 g. Medium-sized sparrow with relatively large bill, flat head, and long, rounded tail. Nominate race has thin buffy-grey median crownstripe, supercilium somewhat lighter grey behind eye, buffy in front of eye, enclosed by dull rusty to brown lateral crownstripe and postocular stripe; pale buff eyering, side of face and throat buffy, thin malar stripe; upperparts brown with strong blackish and rusty-brown streaking (centres of feathers often blackish); tail brown to rusty brown; upperwing brown, washed rusty, yellow at bend of wing; underparts greyish-buff, belly contrastingly whitish; iris dark brown; upper mandible dusky, lower mandible paler; legs flesh-colour to pink. Sexes similar. Juvenile has crown and back dark brown or black, mantle and scapulars edged buffy or reddish-brown (but less rufous than adult), underparts whitish or creamy, breast and flanks streaked with brown. Race *bachmani* is like nominate, but is more rusty on head and upperparts; *illinoensis* is even more rusty than previous, and generally paler, with buffy wash on breast. Voice. Song, sometimes in short aerial display, highly variable but distinctive, generally consists of a long, sweet note followed by a clear trill, sometimes also with a third element; flight song (uncommon) sometimes more bubbling and exuberant. Call a thin, high "chip" or "pseet".
Habitat. Lowland pine (*Pinus*) savanna, particularly mature, open pine forest with fairly rank understorey of wiregrass (*Aristida stricta*), palmettos (*Serenoa*) and weeds; also in clear-cuts with grassy undergrowth, and in oak–palmetto (*Quercus–Serenoa*) scrub and grasslands away from pines. Found in limestone glades where growth of woody vegetation limited by poor soil and fire. In N found in degraded pastures, often brushy hillsides; in Indiana occurs in overgrown old fields with broomsedge (*Andropogon virginicus*), deciduous trees and red cedars (*Juniperus virginiana*). Sea-level to 900 m.
Food and Feeding. Feeds on grass seeds (e.g. *Panicum*), also on insects, primarily beetles (Coleoptera) and lepidopteran larvae; young fed mostly with insects. Forages on ground, gleaning from surface; jumps to glean or catch prey. Occasionally searches low in bushes. Shy. Singly and in pairs.
Breeding. Season mid-Apr through Sept; often double-brooded. Monogamous; apparently pairs relatively quickly after arrival on breeding grounds, but nest-building delayed by several weeks after pair formation. Male sometimes performs aerial display with song. Nest built by female, accompanied by male, a cup (may be domed) constructed from grasses and rootlets, lined with finer grasses and horsehair, placed on ground, usually (not always) in dense cover at base of grass clump, small shrub or pine seedling; closely associated with clumps of broomsedge or wiregrass when nesting. Clutch 1–5 eggs, most commonly 4, whitish or pale blue and unspotted; incubation by female, period 12–14 days; chicks fed by both parents, nestling period 9–10 days. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migration poorly known, as species becomes difficult to see when not singing. N populations migratory; S populations resident. In spring, arrival in breeding areas between late Mar and mid-Apr; autumn migration even less well understood, spans period from late Aug to late Oct. Race *illinoensis* recorded as casual visitor N to S Canada (Ontario) and in USA in NE Kansas, Michigan, New York and New Jersey.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Locally common in optimum habitat; uncommon to rare in many places. During 1890–1915, expanded range N to N Illinois, C Ohio and SW Pennsylvania (with records even to S Ontario) following farm abandonment, and into South Carolina following clearing of old pine forests. Now uncommon or irregular N of Carolinas, SC Kentucky and SC Missouri. Global population estimated at 250,000 mature individuals, and decreasing. Declined at fairly rapid rate for several decades, but rate of decline now slower. Now absent over most of N parts of range and uncommon in most of S because of logging, fire suppression and habitat fragmentation, such that many suitable habitat patches no longer occupied. In some areas suffers some disturbance by birdwatchers. S pine forests often clear-cut and managed in a way that does not benefit this species; on the other hand, it can be common in areas managed to protect Red-cockaded Woodpecker (*Picoides borealis*) and where understorey regularly burnt, keeping down growth of woody vegetation. Occurs in many protected areas.
Bibliography. Anon. (1998, 2010c), Beadle & Rising (2002), Brooks (1938), Butchart & Stattersfield (2004), Cox & Jones (2004), Dorsey (1976), Dunning (1993a), Dunning & Watts (1990, 1991), Haas & Titus (1998), Haggerty (1988, 1992, 1995, 1998, 2000), Hellmayr (1938), Lebbin *et al.* (2010), McKitrick (1979), McNair & Nicholson (1991), Meanley (1959, 1989, 1990), Mengel (1951), Murray *et al.* (2004), Nicholson (1976), Perkins & Vickery (2005), Perkins *et al.* (2009), Pittman (1960), Plentovich, Tucker *et al.* (1998), Rising & Beadle (1996), Stattersfield

101. **Botteri's Sparrow**

Peucaea botterii

French: Bruant de Botteri **German**: Botteriammer **Spanish**: Chingolo de Botteri
Other common names: Peten/Yellow-carpalled Sparrow (*petenica/vantynei/spadiconigrescens/vulcanica*)

Taxonomy. *Zonotrichia botterii* P. L. Sclater, 1858, vicinity of Orizaba, Veracruz, Mexico.
Formerly placed in *Aimophila*, but molecular-genetic studies indicate that such treatment would make that genus polyphyletic. Closely related to *P. cassinii* and *P. aestivalis*, all having aerial song displays; molecular analyses suggest that this group is close to a clade consisting of *P. ruficauda*, *P. humeralis*, *P. mystacalis*, *P. sumichrasti* and *P. carpalis*. S races *petenica*, *vantynei*, *spadiconigrescens* and *vulcanica* have in the past been considered to represent a separate species. Race *petenica* intergrades with nominate in E Mexico (Veracruz). Some races poorly differentiated, grading clinally into others; *texana* sometimes considered synonymous with *arizonae*; proposed race *tabascensis* (described from S Huimanguillo, in W Tabasco) included within *petenica*. Nine subspecies recognized.
Subspecies and Distribution.
P. b. arizonae Ridgway, 1873 – extreme S USA in SE Arizona (Cochise County) and SW New Mexico, possibly also W Texas, and N Mexico S to S Sonora and N Durango and discontinuously in N & S Coahuila; non-breeding also to SC Mexico (Morelos).
P. b. texana (A. R. Phillips, 1943) – S Texas and NE Mexico (E Tamaulipas).
P. b. goldmani (A. R. Phillips, 1943) – W coast of Mexico from S Sinaloa S to Nayarit.
P. b. mexicana (Lawrence, 1867) – C highlands of Mexico from SE Durango, Zacatecas and San Luis Potosí S to Colima, C Michoacán and Distrito Federal.
P. b. botterii (P. L. Sclater, 1858) – SE & S highlands of Mexico from S San Luis Potosí S through Puebla and W Veracruz to C Guerrero, Oaxaca and W Chiapas.
P. b. petenica (Salvin, 1863) – lowlands of SE Mexico from EC Veracruz (near city of Veracruz), Tabasco and E Chiapas E to N Yucatán, N Guatemala (Petén) and Belize.
P. b. vantynei (Webster, 1959) – highlands of C Guatemala.
P. b. spadiconigrescens (T. R. Howell, 1965) – lowlands of N Honduras and NE Nicaragua.
P. b. vulcanica (W. deW. Miller & Griscom, 1925) – highlands of W Nicaragua and NW Costa Rica.
Descriptive notes. 13·5–15 cm; 15·7–25·5 g. A medium-sized sparrow with large bill, flat head, and long, rounded tail. Nominate race is moderately dark brown in appearance, has crown to upperparts greyish, streaked dark brown, streaks variably edged rufous, scapulars with rufous wash; highly variable, variation difficult to assess (samples from range often include wintering birds from other populations), but dorsally darkest in E San Luis Potosí, Veracruz and Puebla, more reddish in W Chiapas, and apparently paler in Oaxaca; side of face greyish to grey-brown, faint dark eyestripe behind eye, lighter grey supercilium somewhat obscure; tail dark brown, outer pair of feathers paler; upperwing dark brown, feathers with pale rufous-buff edges, bend of wing pale yellow; chin and throat whitish; underparts light brownish to greyish-buff, belly whiter; iris dark brown; upper mandible dusky, lower mandible bluish; legs pinkish. Sexes similar. Juvenile is more buffish generally than adult, has buffy supercilium and lores, throat faintly streaked, buff breast, and thin brown streaks on breast and flanks. Races differ mainly in plumage tones: *arizonae* is much more rufous above than nominate; *texana* is pale, clearly paler and greyer above than nominate; *goldmani* is

similar to *arizonae*, but darker red above; *mexicana* is darker above than previous, with streaks broader and blackish; *petenica* is small, very dark, almost blackish (with greyish feather edges) above, and very pale below; *vantynei* is similar to previous, but not quite so dark (dark brown) above and darker below; *spadiconigrescens* is very dark above, like *petenica*, but feather edges browner, also a shade darker below; *vulcanica* resembles *petenica*, but larger, a little less dark above, much more dusky below. Voice. Song, sometimes in short aerial display, characteristically consists of two "che-lick" elements followed by a variable series of notes, "wit-wit-wit-wit-t-t-t-tseee wit wit", becoming more rapid, like a bouncing ball. Call a sharp "chip", "pit" or "tsip".
Habitat. Grasslands, savanna, coastal prairie, pine (*Pinus*) forests, and lowland pine savanna in tropical and subtropical zones; requires perches (e.g. bushes, stone walls, fences) for songposts. In Arizona, breeds in arid grasslands and open oak (*Quercus*) woodland at 1050–1500 m, in open encinal (evergreen woodlands dominated by oak) and sacaton (*Sporobolus*) grasslands; also in upland mesquite (*Prosopis*) and oak woodlands. In coastal Texas and Tamaulipas, breeds in periodically inundated coastal prairie, in saltgrass (*Distichlis*) prairie, and at higher elevations in grasslands with widely separated mesquite, yucca (*Yucca*), huisache (*Acacia farnesiana*) and hackberry (*Celtis pallida*). In Belize, Honduras, and Nicaragua breeds in grasslands in lowland pine ridges. Sea-level to 2500 m.
Food and Feeding. Insects, also seeds of sacaton and other plants. Feeds young with variety of insects, especially grasshoppers (Orthoptera) and stick-insects (Phasmida), larval Lepidoptera, and beetle larvae (Coleoptera). Forages mostly on ground; shy and elusive, often difficult to observe. In pairs; sometimes in small groups, probably family parties.
Breeding. In Arizona season late May through Aug; usually single-brooded; in some areas nesting activities seem to be triggered by rains. Monogamous. Male sometimes performs aerial display with song. Nest constructed from dry grass, lined with fine grasses, rootlets and hair, placed on ground in dense grass, most commonly sacaton, but variety of other species also used; nest woven into the grass, and often has woven entrance way or tunnel. Clutch 2–4 eggs (usually 3) in Arizona, 3–5 (usually 4) in Texas, eggs white and unmarked; incubation by female, period 12 days; chicks fed by both parents, nestling period 10 days. Nests parasitized very rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migratory in far N of range in USA (Arizona, and probably S Texas); resident elsewhere. Absent from Arizona breeding areas Oct–May; in Texas probably absent between Oct and mid-Apr.
Status and Conservation. Not globally threatened. Locally abundant in N of range (USA); fairly common to common in Mexico and S to Costa Rica, becoming more local in S parts. At risk in Texas as a result of habitat loss. Habitat loss may have caused this species' extirpation in Arizona in 19th century, but it recovered in numbers in 20th century.

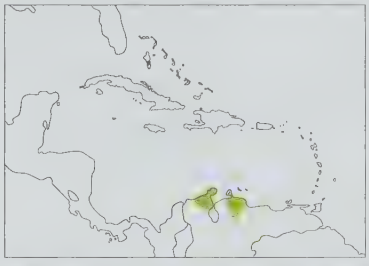
Genus *ARREMONOPS* Ridgway, 1896

102. Olive Sparrow

Arremonops rufivirgatus

French: Tohi olive **German**: Olivrückenammer **Spanish**: Cerquero Oliváceo
Other common names: Schott's Sparrow; Texas Sparrow (*rufivirgatus*); Nicoya/Pacific Sparrow ("Pacific group"); Yucatan Sparrow ("Yucatan group")

Taxonomy. *Embernagra rufivirgata* Lawrence, 1851, Brownsville, Texas, USA.
Relationships of genus not well understood; molecular evidence suggests that it is close to *Rhynchospiza*, *Peucaea* and some *Ammodramus*. This species sometimes considered to form a superspecies with *A. tocuyensis*. Races form three groups, "*rufivirgatus* group" (*rufivirgatus*, *ridgwayi* and *crassirostris*), brighter-plumaged "Yucatan group" (*verticalis* and *rhyptothorax*), and even brighter and shorter-tailed "Pacific group" (*superciliosus*, *sinaloae*, *sumichrasti* and *chiapensis*); these sometimes considered to represent three separate species, but further study needed. Race *ridgwayi* weakly differentiated, and possibly an intergrade between nominate and *crassirostris*; *verticalis* intergrades with *crassirostris* in E Tabasco and Campeche and with *rhyptothorax* in C Yucatán. Nine subspecies recognized.
Subspecies and Distribution.
A. r. sinaloae Nelson, 1899 – W Mexico from C Sinaloa S to Nayarit.
A. r. sumichrasti (Sharpe, 1888) – W coast of Mexico from Jalisco, Colima, Michoacán and Guerrero S to Isthmus of Tehuantepec (Oaxaca).
A. r. rufivirgatus (Lawrence, 1851) – extreme S USA (S Texas) and NE Mexico from NE Coahuila (San Juan de Sabinas) and Nuevo León S to S coastal Tamaulipas.
A. r. ridgwayi (Sutton & Burleigh, 1941) – S interior of Tamaulipas, E San Luis Potosí, Hidalgo and N Veracruz.
A. r. crassirostris (Ridgway, 1878) – Atlantic coast of SE Mexico from C & S Veracruz S to E Puebla and N Oaxaca and E Tabasco.
A. r. verticalis (Ridgway, 1878) – E Tabasco and Yucatán Peninsula (SE Mexico) S to N Guatemala (Petén) and N Belize.
A. r. rhyptothorax Parkes, 1974 – N Yucatán Peninsula.
A. r. chiapensis Nelson, 1904 – C valley of Chiapas, in S Mexico.
A. r. superciliosus (Salvin, 1865) – Pacific coast of Costa Rica from Nicaragua border S to Santo Domingo.



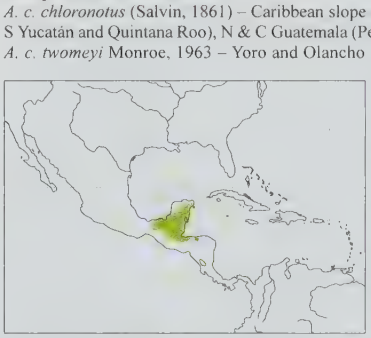
Descriptive notes. 13·5–15 cm; 15–30 g (Texas). A fairly stout, dull olive-green sparrow. Nominate race has head dull grey, dull brown lateral crownstripe, thin brown eyestripe; upperparts, including upperwing and tail, dull olive-green, bright yellow bend of wing; throat greyish-white; underparts pale greyish to greyish-green with dull buff wash, belly paler, undertail-coverts more buffish; iris brown; upper mandible dusky, lower mandible paler horn; legs light brownish. Sexes similar. Juvenile is mostly brownish, paler below, with brown streaking on crown, nape, mantle, throat, breast and flanks. Races differ in overall size, bill size, and colour of crown stripes and underparts, nominate with thinner bill than others: *ridgwayi* is intermediate between nominate and *crassirostris*; *crassirostris* is darker and browner, with more rusty diffuse lateral crownstripes, deep buff-brown flanks, relatively large and thick bill; *verticalis* is brighter above than previous races, has lateral crownstripes narrower, more sharply defined and streaked with black (especially in front of eye); *rhyptothorax* has upperparts and tail paler and less richly green than last, underparts whiter; *superciliosus* has lateral crownstripes dark chestnut, supercilium distinctly buff, upperparts bright olive-green, breast and flanks strongly washed buff; *sumichrasti* has lighter chestnut head-stripes than previous; *chiapensis* has dark green back and darker grey median crownstripe than last; *sinaloae* is greyer in general than *sumichrasti*. Voice. Song a monotonous series of accelerating chipping notes, "chip chip chip chip chip-chip-chip-chipchipchipchip". Call a squeak or insect-like buzz.
Habitat. Tangles of thorny shrubs, e.g. mesquite (*Prosopis*), Texas ebony (*Pithecollobium flexicaule*), huisache (*Acacia smallii*) and retama (*Parkinsonia aculeata*), and streamside cane, willow (*Salix*) and live oak (*Quercus*); humid evergreen forest and edge. Sea-level to 1800 m.
Food and Feeding. Few data on diet; known to consume small insects, spiders (Araneae), seeds, and occasionally fruits. Forages principally on ground and low in vegetation. Often uses "double-scratch" method, whereby it remains stationary and scratches backward with both feed simultaneously, exposing food under litter. Generally singly and in pairs; occasionally in small parties, presumably families.
Breeding. Nests with eggs mid-Mar to early Sept in Texas (lower Rio Grande Valley), but most nest May–Jun and Aug–Sept, and apparently double-brooded; season may be shorter (late Mar to early Jun) in drier thorn-scrub habitats; May–Aug in S Mexico and Apr–Jul in Costa Rica. Nest domed, with side entrance, constructed from twigs, grasses and stems, sparse lining sometimes of a few finer grasses and hair, placed generally no more than 1·5 m from ground in low bush or cactus in densely vegetated area. Clutch 2–5 eggs, white to pale pinkish and unspotted; incubation by female, no information on duration; no information on other aspects of parental care and nestling period. Nests parasitized by Bronzed Cowbird (*Molothrus aeneus*); most nests of present species in S Texas are parasitized, and clutches reduced by 78% by the parasite.
Movements. Generally sedentary; some may move during very cold seasons, or because of drought.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat; common to fairly common in most of Mexico, but uncommon in NE Coahuila (San Juan de Sabinas). Populations in S Texas have declined since early 1930s because of widespread brush removal, but still locally common.
Bibliography. Armani (1985), Binford (1989), Brush (1998a), Carter (1986), Dunning (2008), Fischer (1978), Howell & Webb (1995), Land (1970), McCarthy (2006), Oberholser (1974), Parkes (1974a), Ridgway (1901), Rising & Beadle (1996), Russell (1964), Stiles & Skutch (1989), Urban (1959), Vega & Rappole (1994).

103. Tocuyo Sparrow

Arremonops tocuyensis

French: Tohi de Tocuyo **German**: Tocuyoammer **Spanish**: Cerquero de El Tocuyo

Taxonomy. *Arremonops tocuyensis* Todd, 1912, Tocuyo, Lara, Venezuela.
Relationships of genus not well understood; molecular evidence suggests that it is close to *Rhynchospiza*, *Peucaea* and some *Ammodramus*. This species sometimes considered to form a superspecies with *A. rufivirgatus*. Monotypic.
Distribution. NE Colombia (Guajira Peninsula) and NW Venezuela (N Zulia, Falcón and Lara).



Descriptive notes. 13–14 cm. A relatively small sparrow with long tail and medium-sized bill. Largely olive above, off white below, with greyish head striped with black. Has grey head, including median crownstripe, with broad blackish lateral crownstripes coalescing on nape–hindneck, broad pale grey supercilium (slightly paler than median crownstripe), blackish eyeline, including lores, greyish ear-coverts (darker than median crownstripe and supercilium); upperparts plain olive; tail dusky, feathers edged dull olive-green; wing with vivid greenish-olive wash, including edging of flight-feathers, folded wing shows yellow at edge of shoulder; throat and underparts white, breast tinged smoke-grey and flanks and undertail-coverts buffy cream; underwing-coverts pale yellow; iris brownish; upper mandible blackish, lower mandible contrastingly leaden blue; legs dark pinkish. Sexes alike. Juvenile is generally olive-yellow and streaked both above and below, head lacks striped pattern of adult, instead has pale yellowish supercilium, with crown slightly darker and streaked. Voice. Song, from partially hidden perch 1–4 m up, most often at dawn, variable, tends to break out into three distinct parts, e.g. "tit, tit'ti'ti'ti'tsuee tsuee" or "sweeu sweeu eeee tu'tu'tu'tu", softer and sweeter than that of *A. conirostris*. Call a high-pitched "tiip".
Habitat. Thickets and shrubby sites adjacent to arid dry forest in tropical zone; general preference for shrubby borders of low-canopy deciduous forest, also patches of thorn-scrub and other dry shrubby sites, often adjacent to tall grass. Absent from driest sites dominated by acacia (*Acacia*) and cacti. Sea-level to 200 m, exceptionally to 1100 m.
Food and Feeding. Little known. Tends to forage on or near ground, singly and in pairs. Very inconspicuous and difficult to see.
Breeding. Nest a domed structure with side entrance, built from leaves, rootlets and twigs, lined with fine rootlets, placed usually on ground under bush or very low down in bush. Clutch 2–3 eggs, white. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Uncommon to fairly common, and local. Despite the fact that this species has a small range, its numbers appear to be stable; no clear imminent threat to populations.
Bibliography. Armani (1985), Byers, Curson & Olsson (1995), Hilty (2003), Restall *et al.* (2006), Ridgely & Tudor (1989), Todd (1912).

104. Green-backed Sparrow

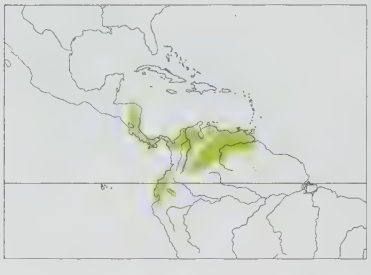
Arremonops chloronotus

French: Tohi à dos vert **German**: Grünrückenammer **Spanish**: Cerquero Dorsiverde

Taxonomy. *Embernagra chloronota* Salvin, 1861, Choctum, Alta Verapaz, Guatemala.
Relationships of genus not well understood; molecular evidence suggests that it is close to *Rhynchospiza*, *Peucaea* and some *Ammodramus*. Sometimes considered conspecific with *A. conirostris*, with which virtually sympatric in NC Honduras, but differs significantly in juvenile plumage, size and vocalizations. Two subspecies recognized.
Subspecies and Distribution.
A. c. chloronotus (Salvin, 1861) – Caribbean slope of SE Mexico (from Tabasco and N Chiapas E to S Yucatán and Quintana Roo), N & C Guatemala (Petén and Alto Verapaz), Belize and NW Honduras.
A. c. twomeyi Monroe, 1963 – Yoro and Olancho Departments, in NC Honduras.

Descriptive notes. 15–16 cm; 15–31·2 g. A fairly stout, dull olive-green sparrow with striped head. Nominate race has head dull greenish-grey, with long dull blackish lateral crownstripe and eyestripe; upperparts, including tail, dull olive-green; upperwing feathers dark brown with broad olive edges, edges narrower and yellower on remiges, bright yellow bend of wing; throat greyish-white; breast and flanks greyish-green, belly paler, undertail-coverts yellowish; iris dark red-brown; upper mandible blackish, lower mandible dull blue-grey; legs flesh-coloured. Sexes similar in coloration. Juvenile is like adult, but duller. Race *twomeyi* is slightly smaller than nominate, has grey parts of head paler, greyish-white (rather than grey), upperparts brighter green, breast light buff (not grey). Voice. Song 1–2 introductory notes followed by a series of chipping notes, "chew-chew-chew-chew-chew", or a series of 8–10 paired notes, "tur chip, tur chip, tur chip..."; unlike song of *A. rufivirgatus*, does not accelerate. Call a sharp "pink", thin "tsik", "seeee" or "seet".
Habitat. Tropical lowland evergreen forest and edge, and coffee plantations, from sea-level to 900 m. Race *twomeyi* found in arid scrub and thorn-forest.
Food and Feeding. Seeds, as well as insects and berries. Forages principally on ground and low in vegetation. Shy. Usually singly or in pairs; occasionally small groups, presumed family parties.

On following pages: 105. Black-striped Sparrow (*Arremonops conirostris*); 106. Pectoral Sparrow (*Arremon taciturnus*); 107. Half-collared Sparrow (*Arremon semitorquatus*); 108. Sao Francisco Sparrow (*Arremon franciscanus*); 109. Saffron-billed Sparrow (*Arremon flavirostris*); 110. Orange-billed Sparrow (*Arremon aurantiirostris*); 111. Golden-winged Sparrow (*Arremon schlegeli*); 112. Black-capped Sparrow (*Arremon abeillei*).



Breeding. Nesting observed in late Apr and early May in C Guatemala (Chamá). Nest domed, with side entrance, made from grass, rootlets and twigs, lined with finer materials, placed in low bush, or on ground under bush and between tree roots or other thick vegetation. Clutch 3 eggs, sometimes 4, whitish. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common to common in appropriate habitat. Status of race *twomeyi* uncertain.
Bibliography. Armani (1985), Griscom (1932), Howell & Webb (1995), Jones (2003), McCarthy (2006), Monroe (1963, 1968), Ridgway (1901), Salgado-Ortiz *et al.* (2001), Skutch (1954), Todd (1923b).

105. **Black-striped Sparrow**

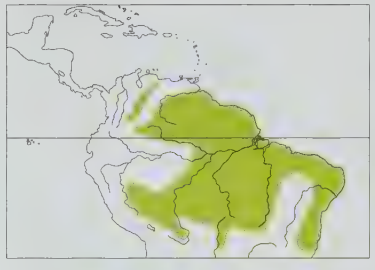
Arremonops conirostris

French: Tohi ligné **German**: Panamaammer **Spanish**: Cerquero Negrilistado

Taxonomy. *Arremon conirostris* Bonaparte, 1850, Brazil; error = Colombia.
Relationships of genus not well understood; molecular evidence suggests that it is close to *Rhynchospiza*, *Peucaea* and some *Ammodramus*. Sometimes considered conspecific with *A. chloronotus*, with which virtually sympatric in NC Honduras, but differs significantly in juvenile plumage, size and vocalizations. Seven subspecies recognized.
Subspecies and Distribution.
A. c. richmondi Ridgway, 1898 – tropical zone from E Honduras S to W Panama.
A. c. viridicatus Wetmore, 1957 – Coiba I, off Veraguas, in S Panama.
A. c. striaticeps (Lafresnaye, 1853) – C & E Panama (both slopes) and Pacific slope of Colombia S to W Ecuador.
A. c. conirostris (Bonaparte, 1850) – Caribbean coast of Colombia from Bolívar (upper Sinú Valley) E to foothills of Santa Marta Mts, S in Magdalena Valley (except uppermost parts), also E slopes of E Andes in Arauca and Boyaca; also N & W Venezuela (Falcón and Lara E to Sucre, S to SW Táchira, Apure, Guárica and N Bolívar) and extreme N Brazil (R Branco region).
A. c. inexpectatus Chapman, 1914 – arid tropical and subtropical zones of upper Magdalena Valley, in Colombia.
A. c. umbrinus Todd, 1923 – E Colombia (Norte de Santader) and W Venezuela (S & W of L Maracaibo).
A. c. pastazae Krabbe & Stejskal, 2008 – E Ecuador (R Pastaza, in Pastaza).

Descriptive notes. 16·5 cm; 26–42 g. Boldly striped head and plain back. Nominate race has head grey, with broad black lateral crownstripe, narrow black eyestripe; upperparts, including wings and tail, olive-green, yellow at bend of wing; throat whitish; underparts pale grey, belly whitish, rear flanks and undertail-coverts with olive-buff wash; iris dark red-brown; bill blackish; legs flesh-coloured to brownish-grey. Sexes alike in coloration. Juvenile has yellowish-olive head striped with dark brown, upperparts brownish-olive and streaked with dusky, underparts yellowish-olive and boldly streaked, flanks streaked dark brown, bill yellowish at base; adult plumage acquired at c. 4 months of age. Races differ rather little, mainly in size and in plumage tones: *richmondi* is like nominate, but slightly smaller, also much brighter olive above, grey of head darker, chest ash-grey; *striaticeps* has black stripes on crown narrow, green of upperparts lighter and more yellowish, grey on underparts paler and less extensive; *viridicatus* is like previous, but darker; *inexpectatus* is dullest and smallest, brownish-olive on upperparts; *umbrinus* also is relatively small and dull, but larger and brighter than last; *pastazae* is similar to nominate, but larger, with proportionately larger bill, greyer upperparts with little or no greenish tone, throat pure white, belly whiter, undertail-coverts light greyish. Voice. Song a series of whining notes with rising or downward inflection, preceded by clear, thin accelerated whistles, "seee-seee-seee churry-churry-churry", or "tock tock chuck, tock tock chuck"; in Guatemala a ringing "ching ching ching ching". Call a metallic, nasal "churk" or "tsook"; in Guatemala a sharp, but soft, metallic "pink".
Habitat. Low thickets, weedy fields, young second growth, shaded gardens and humid woodland edges; sea-level to 1600 m. In E Ecuador, race *pastazae* found in dense stands of the shrub *Tessaria integrifolia* growing on temporary river sandbars.
Food and Feeding. Variety of insects, especially grasshoppers and other orthopterans, also seeds, and fruits (e.g. berries from *Miconia* trees); occasionally takes small vertebrates (small lizards and frogs). Will feed on fruit (bananas, oranges) on feeding shelves, and dried maize. Seen to feed what were probably newborn mice (Muridae) to young. Forages on and near ground; hops, but does not walk on ground. Also gleans insects from low vegetation.
Breeding. Season Jan–Oct, but most nesting activity in Apr–Jul, e.g. Apr–May (sometimes to Dec) in Colombia; perhaps sometimes double-brooded. Nest built by female, a bulky, oven-shaped structure with entrance at side, built from coarse leaves, ferns, grasses, weed stems and/or banana leaves, lined with finer material, placed up to 2 m above ground in dense vegetation. Clutch 2 eggs, rarely 1 or 3, whitish and unmarked; incubation by female, period 13–14 days; chicks fed by both parents, nestling period c. 11 or 12 days; fledglings accompanied by parents.
Movements. Sedentary; a few may move upslope to breed.
Status and Conservation. Not globally threatened. Fairly common to common in appropriate habitat in most of range. Often difficult to detect; possibly more numerous than may appear. Newly described race *pastazae* appears to be locally common.
Bibliography. Armani (1985), Dunning (2008), Howell & Webb (1995), Krabbe & Stejskal (2008), Monroe (1963, 1968), Moynihan (1963a), Parker *et al.* (1995), Skutch (1954, 1983).

Genus *ARREMON* Vieillot, 1816



106. **Pectoral Sparrow**

Arremon taciturnus

French: Tohi silencieux **German**: Schwarzbrust-Buschammer **Spanish**: Cerquero Pectoral

Other common names: Yellow-shouldered Sparrow (*axillaris*)

Taxonomy. *Tanagra taciturna* Hermann, 1783, Cayenne, French Guiana.
Until recently considered conspecific with *A. semitorquatus*. In recent study found to be parapatric with latter, and no intermediate specimens or evidence of gene flow. Three subspecies recognized.
Subspecies and Distribution.
A. t. axillaris P. L. Sclater, 1855 – E of base of E Andes in Venezuela (Portuguesa S to E Táchira) and Colombia (Boyacá, Casanare and Meta).
A. t. taciturnus (Hermann, 1783) – E Colombia (in R Orinoco valley), Venezuela (Bolívar and Amazonas), the Guianas, C & NE Brazil (E from Mato Grosso and Amazonas, S to Minas Gerais and Espírito Santo) and NE Bolivia (Beni).
A. t. nigrirostris P. L. Sclater, 1886 – SE Peru (Cuzco and Puno) and N Bolivia (La Paz and Cochabamba).

Descriptive notes. 15 cm; 22–32 g. A medium-sized, chunky sparrow with relatively thick-based but long bill. Male nominate race has black head, narrow white supercilium that begins immediately before eye (but not reaching bill base), and grey median crownstripe and nape; black ear-coverts and base of malar end at abrupt edge and contrast with white throat and sides of foreneck; upperparts, including upperwing and tail, greenish-olive, becoming vivid yellowish-green on wing-coverts (particularly at shoulder); white of throat contrasts also with black pectoral band, otherwise white below, with greyish wash on flanks; iris dark reddish-brown; bill black; legs grey with pink wash. Female is similar to male, but duller, particularly on underparts: has upperparts duller olive and yellow on shoulder less bright and less extensive, off-white to creamy white below, black pectoral band replaced by narrow greyish or dusky band. Juvenile lacks obvious pattern of adult, has dark olive crown, dusky face with some white on supercilium, yellowish shoulder patch not developed, upperparts dark olive, buffy yellow below, darker breast and flanks. Race *axillaris* has breastband restricted to black spur on each side of breast, yellow on shoulder more extensive and including yellow edging on greater coverts, bill bicoloured, with yellowish lower mandible; *nigrirostris* male has broken breastband like previous, female lacks all evidence of breastband, both sexes have all-black bill like nominate. Voice. Song, from low perch, often a log, sometimes from ground, simple, a series of high-pitched hisses, "zitip, zeee zeee zeee" or "chit-tic-tzzzzz, tzzzzz, tzzzzzz". Call a sharp "tziip".
Habitat. Open undergrowth in humid forest and in older second growth within tropical zone; will utilize coffee plantations when adjacent to some humid forest. Sea-level to 1000 m; may reach 1500 m S of R Orinoco.
Food and Feeding. No information on diet; likely a mix of seeds and arthropods. Forages largely on ground, usually hidden in undergrowth; also in low shrubs in undergrowth. Sometimes forages by scratching at and shifting leaf litter while on ground. Often in pairs.
Breeding. Nest a sphere with side entrance, made from grasses, placed in low shrub or base of palm. Clutch 2 eggs, whitish and spotted with brown and purple. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common. Has reasonably large range; no evidence of population declines.
Bibliography. Armani (1985), Buzzetti & Silva (2005), Dunning (2008), Hilty (2003), Raposo (1997), Restall *et al.* (2006), Ridgely & Tudor (1989), Sick (1993).

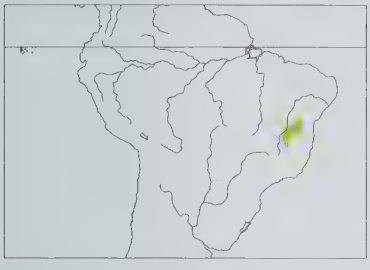
107. **Half-collared Sparrow**

Arremon semitorquatus

French: Tohi à semi-collier **Spanish**: Cerquero Semiacollarado
German: Halsband-Buschammer

Taxonomy. *Arremon semitorquatus* Swainson, 1838, Rio de Janeiro, Brazil.
Until recently considered conspecific with *A. taciturnus*. In recent study found to be parapatric with latter, and no intermediate specimens or evidence of gene flow. Monotypic.
Distribution. Atlantic montane areas of SE Brazil (Espírito Santo S to NE Rio Grande do Sul).

Descriptive notes. 15 cm; 22–28 g. A medium-sized and chunky sparrow with relatively thick-based yet longish bill. Male has black head, narrow white supercilium beginning immediately above bill base, grey median crownstripe, nape and neck sides; black ear-coverts and base of malar end at abrupt edge and contrast with white throat; upperparts, including upperwing and tail, greenish-olive, becoming slightly more vivid and yellowish-green on shoulder (lesser upperwing-coverts); black patch at each side of breast (broken breastband), centre of breast and belly white, flanks grey; iris dark reddish-brown; upper mandible black, lower mandible orange to orange-yellow; legs greyish-pink. Female is similar to male in pattern, but duller, particularly below: upperparts duller olive than on male, throat and underparts off-white to creamy white with buff wash. Juvenile lacks obvious pattern of adult, is dark olive above, with dusky face, little or no yellow at shoulder, buffy yellow below, darker breast and flanks. Voice. Song a high-pitched series of three whistles, each whistle descending in frequency, and each lower in pitch than previous one, "tzee–tzeuuu-tzééúúúú", sometimes 4 notes involved; a second type of song follows an up-down, up-down pattern, "swee-swóóó swee-swóóó". Call a sharp ringing "tiip" with metallic quality.
Habitat. Occupies undergrowth and understorey of montane forest, second growth, and overgrown fields and gardens; attracted particularly to gulleys with shrubby growth. Recorded at elevations of 300–1000 m.
Food and Feeding. No details of diet. Forages on ground, often by scratching in leaf litter. Tends to be found singly, sometimes in pairs or family groups.
Breeding. Season appears to be in austral spring, Sept–Dec; birds in moult by Feb. Nest a large bulky sphere made from dry grasses, twigs and dry leaves, placed on or near ground. Clutch 2 eggs, whitish with brownish spots and blotches. No other information.



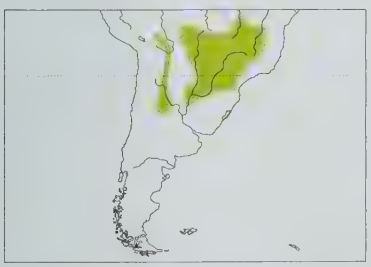
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Has small but sufficiently extensive range. Apparently, no imminent threats to this species' habitat or populations.
Bibliography. Armani (1985), Euler (1900), Mallet-Rodrigues & Marinho de Noronha (2009), Mitchell (1957), Raposo (1997), Raposo & Parrini (1997), Willard *et al.* (1991).

108. Sao Francisco Sparrow

Arremon franciscanus

French: Tohi du Sao Francisco **Spanish**: Cerquero Franciscano
German: Franziskusbuschammer

Taxonomy. *Arremon franciscanus* Raposo, 1997, Rio São Francisco, Minas Gerais, Brazil. Monotypic.
Distribution. S Bahia and N Minas Gerais, in E Brazil.



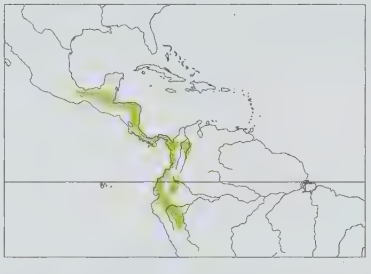
Descriptive notes. 15 cm; 21–25 g. A medium-sized, chunky sparrow with relatively thick-based, longish bill; comparatively shorter-tailed and longer-billed than *A. semitorquatus*. Male has black head, wide white supercilium beginning immediately above bill base, narrow whitish median crownstripe, grey nape and neck side; black ear-coverts and base of malar end at abrupt edge and contrast with white throat; chin black; upperparts, including upperwing and tail, greenish-olive, sometimes becoming slightly more vivid and yellowish-green on shoulder (lesser upperwing-coverts); black patch at each side of breast (broken breastband), centre of breast and belly white, flanks pale grey; iris dark reddish-brown; upper mandible with black ridge along culmen and orange-yellow sides, lower mandible orange to orange-yellow; legs greyish. Female and juvenile apparently undescribed. Voice. Song variable, tends to be composed of repeated introductory notes, or a more complex series of introductory notes before a trill of varying speed, and is high-pitched and sibilant, commonly "twip-twip tsip-tsip-tsip-tsip"; another variant has up-down pattern in introductory notes, then trill, "tsip-tsup tsip-tsup chp-chp-chp-chp". Call a sharp ringing "tiip" with metallic quality.
Habitat. Found in thick xerophitic *caatinga* scrub; also in undergrowth and edge of taller "arboreal" *caatinga* (at Mata do Jaíba), but tending to keep to lower and denser scrub.
Food and Feeding. Appears to forage while on ground. No other information.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to locally fairly common. Has small range, within which it is patchily distributed. Declines in population are suspected owing to degradation of *caatinga* scrub. However, a recent survey assessed the species' overall range as covering c. 56,000 km², which would suggest that it may be more secure than hitherto reckoned; population thought unlikely to number less than 10,000 mature individuals. Further fieldwork required in order to determine if it has suffered, or is currently undergoing, serious decline in numbers. Occurs in Chapada Diamantina National Park and Cavernas do Peruaçú Environmental Protection Area.
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), D'Angelo Neto & de Vasconcelos (2004, 2005), Kirwan *et al.* (2004), Raposo (1997), Stattersfield & Capper (2000), de Vasconcelos, D'Angelo Neto *et al.* (2006).

109. Saffron-billed Sparrow

Arremon flavirostris

French: Tohi à bec jaune **German**: Gelbschnabel-Buschammer **Spanish**: Cerquero Piquiamarillo

Taxonomy. *Arremon flavirostris* Swainson, 1838, interior of Bahia, Brazil.
Has been suggested as forming a superspecies with *A. taciturnus*, *A. aurantiirostris*, *A. schlegeli* and *A. abeillei*. Four subspecies recognized.
Subspecies and Distribution.
A. f. dorbignii P. L. Sclater, 1856 – C & S Bolivia (Cochabamba, W Santa Cruz, Chuquisaca and Tarija) and NW Argentina (Jujuy and Salta S to Catamarca).
A. f. devillii Des Murs, 1856 – E Bolivia (E Santa Cruz) and C Brazil (C Mato Grosso E to W Goiás and W São Paulo).
A. f. flavirostris Swainson, 1838 – C & E Brazil (SE Mato Grosso E to S Goiás, Bahia, W Minas Gerais and N & C São Paulo).
A. f. polionotus Bonaparte, 1850 – S Brazil (S Mato Grosso and W Paraná), Paraguay and NE Argentina (Misiones, Corrientes, E Formosa and E Chaco).



Descriptive notes. 15–16·5 cm; 20–33 g. A stocky, long-billed and short-tailed sparrow. Male nominate race has head black, bold white supercilium from above eye back to nape side, black ear-coverts contrasting strongly with snow-white throat; nape and uppermost mantle grey, rest of upperparts, including wings and tail, green, bend of wing yellow; white of throat separated from white underparts by narrow blackish pectoral line, flanks greyish; iris dark brown; bill orange-yellow to orange-red, black along culmen; legs pink to grey. Female is similar to male, but slightly duller in coloration (evident in direct comparison), with white areas tinged more or less buff. Juvenile is similar to adult, but duller all over. Race *dorbignii* is mostly green on upperparts, like nominate, but has broad grey central crownstripe, full white supercilium usually extending anteriorly to bill base, also pectoral band very narrow; *devillii* has upperparts grey, with olive restricted to wing-coverts; *polionotus* is entirely grey on upperparts, with yellow bend of wing, has supercilium as in nominate, narrow trace of a grey central crownstripe. Voice. Song, from ground or low perch, a series of high-pitched hissing notes, "tsit, tsee-tsi-tsi, tseep-seep-tseep". Call a faint "tseet".
Habitat. Undergrowth of deciduous woodland, as well as thickets at edge of moist tropical forest; in Paraguay ranges from subhumid forest and scrub-forest to humid forest edge. Although a forest species, usually found near edges, trails, or clearings or treefall gaps. Sea-level to 1400 m.
Food and Feeding. No information on diet. Forages terrestrially, usually hidden in understorey but may come into the open at edge of shrubbery. Singly and in pairs or family groups.
Breeding. Nest a large cup made from dry grasses and vegetation, placed on ground. Clutch 3 eggs, in Argentina light buff or bluish-grey with chocolate-brown or light brown speckles and scrawls. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common. Has large range, within which it appears to be a generalist of forest and forest-edge habitat. No evidence of any decline, and no known threats.
Bibliography. Armani (1985), Canevari *et al.* (1991), Hayes (1995), de la Peña (1989), Ridgely & Tudor (1989), da Silva (1991), Storer (1989b), Tye & Tye (1992), Wetmore (1926).

110. Orange-billed Sparrow

Arremon aurantiirostris

French: Tohi à bec orange **Spanish**: Cerquero Piquinaranja
German: Goldschnabel-Buschammer

Taxonomy. *Arremon aurantiirostris* Lafresnaye, 1847, Panama.
Has been suggested as forming a superspecies with *A. taciturnus*, *A. flavirostris*, *A. schlegeli* and *A. abeillei*. Eight subspecies recognized.
Subspecies and Distribution.
A. a. saturatus Cherrie, 1891 – Caribbean slope of SE Mexico (S Veracruz, N Oaxaca, NE Chiapas and Tabasco), N & C Guatemala (Petén, Alta Verapaz and Izabal) and Belize.
A. a. rufidorsalis Cassin, 1865 – Caribbean slope from Honduras S to extreme NW Panama.
A. a. aurantiirostris Lafresnaye, 1847 – Pacific slope of Costa Rica and both slopes of Panama (E to Canal Zone).
A. a. strictocollaris Todd, 1922 – extreme E Panama and adjacent Colombia (N Chocó).
A. a. occidentalis Hellmayr, 1911 – Pacific slope of W Colombia (S from middle Atrato Valley) and NW Ecuador.
A. a. erythrorhynchus P. L. Sclater, 1855 – N Colombia in upper Sinú Valley, lower Cauca Valley and middle Magdalena Valley.
A. a. spectabilis P. L. Sclater, 1855 – SE Colombia (Putumayo) S through E Ecuador to NC Peru (San Martín).
A. a. santarosae Chapman, 1925 – SW Ecuador S from Chimbo Valley.

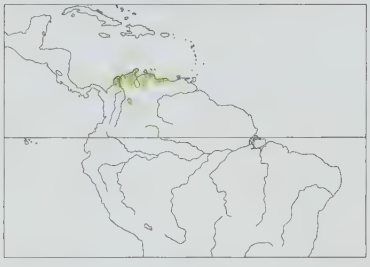
Descriptive notes. 14·5–16·5 cm; mean 34·5 g (Costa Rica). Medium-sized, chunky sparrow with stout bill. Nominate race has black head, including chin and malar area, with grey median crownstripe, white supercilium becoming greyish posteriorly (sometimes most of supercilium grey), and white throat and side of foreneck; hindneck grey, upperparts olive-green, wing and tail darker green, yellow bend of wing; broad black breastband, belly whitish, flanks grey; iris dark brown; bill bright orange; legs pale brownish. Sexes alike in coloration. Juvenile is mostly brown above, with paler supercilium and throat, breastband narrower than on adult, flanks greener, bill dark. Races differ mainly in size and in plumage darkness: *saturatus* is larger and darker than nominate; *rufidorsalis* has wider and longer supercilium extending forwards nearly to bill, and lacking grey wash posteriorly; *strictocollaris* has extensive black on face, narrow supercilium, grey throat, and black crescent on breast; *occidentalis* brighter olive-green above than nominate, has grey crownstripe and whitish supercilium, wing bend orange, remiges brown and contrasting with olive coverts, narrow black breastband, underparts whiter, legs pale pink to flesh-coloured; *erythrorhynchus* similar to previous but with paler central crownstripe, more citrine upperparts, brighter, lemon-yellow bend of wing, brighter bill colour; *spectabilis* has central crownstripe darker and smaller than in nominate, supercilium pale, upperparts strongly tinged olive-brown, bend of wing flame-orange, paler underparts with much narrower breastband; *santarosae* similar to *erythrorhynchus* but with broader breastband and rather browner upperparts. Voice. Song on Caribbean slope high-pitched and thin, "ts' seew ts'seew seeew seer", with alternating staccato notes and high, thin whistles; on Pacific slope a tinkling series of high-pitched squeaky or metallic notes. Call a low-pitched "chip".
Habitat. Occupies undergrowth of dense tropical rainforest, forest edge, also guamil (abandoned cultivation with natural regrowth of tall grasses, thorn-scrub and small trees) and thickets; at 240–3500 m.
Food and Feeding. Few data available. Diet includes a variety of insects and seeds. Forages on and near ground. Unobtrusive.
Breeding. Season Feb–Sept in Costa Rica, May–Oct in Panama, and Jan–May in Colombia. Nest a bulky domed or oven-shaped structure with side entrance, built from dead leaves, sticks, grass and fern fronds, lined with fine pale-coloured rootlets, placed in dense tangle of vines 2–4 m from ground in thicket. Clutch 2 eggs, white with brown to blackish markings; incubation by female, period 14–17 days; chicks fed by both parents, nestling period 13 days.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Status not well known owing to the species' elusive nature. Apparently fairly common to common in appropriate habitat. Thought to be an important disperser of seeds of *Calathea inocephala* in Costa Rica.
Bibliography. Armani (1985), Binford (1989), Dunning (2008), Griscom (1932), Hilty & Brown (1986), Howell & Webb (1995), Jones (2003), Miller *et al.* (1957), Moermond (1983), Monroe (1968), O'Daniel (1989), Olson (1983c), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Ridgway (1901), Skutch (1954), Stiles & Skutch (1989), Wetmore *et al.* (1984).

111. Golden-winged Sparrow

Arremon schlegeli

French: Tohi de Schlegel **German**: Goldflügel-Buschammer **Spanish**: Cerquero Alidorado

Taxonomy. *Arremon schlegeli* Bonaparte, 1850, Santa Marta, Colombia.



Has been suggested as forming a superspecies with *A. taciturnus*, *A. flavirostris*, *A. aurantiirostris* and *A. abeillei*. Three subspecies recognized.

Subspecies and Distribution.

A. s. schlegeli Bonaparte, 1850 – Caribbean coast of Colombia (except Guajira Peninsula) and Venezuela, and Venezuelan Andes.

A. s. fratruelis Wetmore, 1946 – Serrania de Macuira (on Guajira Peninsula), in N Colombia.

A. s. canidorsum J. T. Zimmer, 1941 – W slope of E Andes in Santander, in N Colombia.

Descriptive notes. 16 cm; 23–32 g. A stocky and pot-bellied, yet long-billed and short-tailed sparrow. Male nominate race has head down to malar area and side of neck black, connecting to large black patch on side of breast; upper mantle grey, scapulars and lower mantle to rump olive-greenish with yellow tinge, tail dark grey; flight-feathers dark grey, contrasting bright green upperwing-coverts and brighter yellow on bend of wing and shoulder; chin black, throat white; underparts white, flanks very pale grey; iris dark brown; bill bright yellow; legs pinkish-grey. Female is similar to male, but in direct comparison slightly duller in coloration. Juvenile lacks black on head and bright green on wing, is dull brownish-green above, paler below, with dusky streaking on belly, blackish bill; begins to acquire black on head as spots, gradually becoming more like adult. Race *fratruelis* is larger than nominate, with relatively larger bill; *canidorsum* has entirely grey upperparts, including back and rump (but wing-coverts greenish), rear end of black "helmet" blends in gradually with grey of back. Voice. Song, often from low hidden perch in early morning, mostly early in rainy season, a high and thin series of repeated notes, "soot soot soot see". Call "tzip".

Habitat. Open deciduous woodland and arid second growth, also clearings with dense shrubbery in arid areas; 250–1400 m.

Food and Feeding. Diet consists of fruits, insects and seeds. Forages on ground and in undergrowth, sometimes higher up in shrubs. May scratch at leaf litter in search of food items. Solitary and in pairs.

Breeding. Most singing activity occurs early in rainy season, suggesting rainy season breeding period; breeds between Apr and Sept in Colombia. Nest spherical with side entrance, or described as a cup with a domed roof, made from dead leaves and twigs, lined with fine grass, placed 0·5 m up in rock crevice. Eggs pinkish-white, with a few black spots around wide end. No other information available.

Movements. Sedentary.

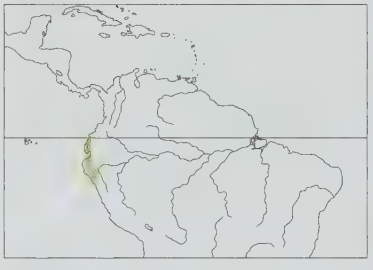
Status and Conservation. Not globally threatened. Uncommon to fairly common. Although this species has a small range, it seems generally to be reasonably numerous. No broad-scale threat apparent.

Bibliography. Armani (1985), Dunning (2008), Hilty (2003), Restall *et al.* (2006), Ridgely & Tudor (1989), Todd & Carriker (1922), Tye & Tye (1992).

112. **Black-capped Sparrow**

Arremon abeillei

French: Tohi d'Abeillé **German**: Kapuzenbuschammer **Spanish**: Cerquero Coroninegro
Other common names: Slaty-backed Sparrow (*abeillei*); Maranon Sparrow (*nigriceps*)



Taxonomy. *Arremon abeillei* Lesson, 1844, Guayaquil, Ecuador.

Has been suggested as forming a superspecies with *A. taciturnus*, *A. flavirostris*, *A. aurantiirostris* and *A. schlegeli*. Distinctive race *nigriceps* possibly merits elevation to full species rank; further study required. Two subspecies recognized.

Subspecies and Distribution.

A. a. abeillei Lesson, 1844 – SW Ecuador (from Manabí) S on Pacific slope to NW Peru (S to Cajamarca).

A. a. nigriceps Taczanowski, 1880 – upper Marañón Valley in E Cajamarca, in NW Peru.

Descriptive notes. 15 cm; average 25·9 g. A stocky, long-billed and short-tailed sparrow. Nominate race has head down to malar area black, except for bold white supercilium from above eye back to nape; upperparts, including wing and tail, blue-grey, very narrow pale wingbars on median and greater coverts of some individuals (possibly only females); throat white, contrasting strongly with well-demarcated black of face side and with black breastband; underparts below breastband white, flanks grey; iris dark brown; bill black; legs flesh-coloured to greyish. Sexes alike. Juvenile undescribed. Race *nigriceps* has upperparts greenish, and white supercilium extending anteriorly to bill base. Voice. Song of nominate race a variable series of high thin whistles and trills, "tsew tsew tsitetetetete"; song of *nigriceps* similar, but slower, "sweée, sweée, si-si-si-si-si-si". Call a dry and high-pitched "ti" or "tik", also a whistled "sweee".

Habitat. Undergrowth of deciduous forest and dry woodland, also second growth and dry scrub; 0–1800 m.

Food and Feeding. No information on diet. Forages on ground; usually scratches in leaf litter under cover of understorey. Singly and in pairs.

Breeding. Singing increases during rainy season, implying that breeding takes place then, Jan–May. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Fairly common within its rather small range. No evidence of any declines; not known to be experiencing any broad-scale habitat problem.

Bibliography. Armani (1985), Restall *et al.* (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

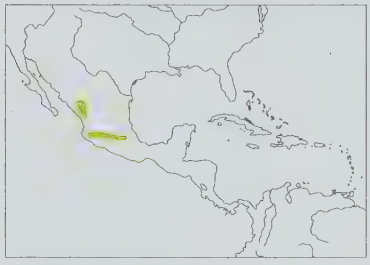
113. Chestnut-capped Brush-finch

Arremon brunneinucha

French: Tohi à nuque brune **Spanish**: Cerquero Coronicastaño
German: Braunkopf-Buschammer
Other common names: Mexican Chestnut-capped Sparrow, Chestnut-capped Atlapetes; Plain-breasted/San Martin Brush-finch (*apertus*)

Taxonomy. *Embernagra brunnei-nucha* Lafresnaye, 1839, Mexico = Jalapa, Veracruz.
Often placed in genus *Buarremon* or *Atlapetes*. Proposed race *nigrilatera*, described from Cerro Baúl (Oaxaca), in S Mexico, considered synonymous with *suttoni*. Nine subspecies currently recognized.
Subspecies and Distribution.
A. b. brunneinucha (Lafresnaye, 1839) – E Mexico from San Luis Potosí and Veracruz S to NE Oaxaca.
A. b. apertus (Wetmore, 1942) – Sierra de Tuxtla, in S Veracruz (Mexico).
A. b. suttoni (Parkes, 1954) – Guerrero E to C Oaxaca, in S Mexico.
A. b. macrourus (Parkes, 1954) – Chiapas (S Mexico) and SW Guatemala.
A. b. alleni (Parkes, 1954) – Honduras, N El Salvador and W Nicaragua.
A. b. elsae (Parkes, 1954) – Costa Rica and W & C Panama.
A. b. frontalis Tschudi, 1844 – extreme E Panama, Colombia, W & N Venezuela (except in Falcón and Yaracuy), Ecuador (except W slope from SW Chimborazo S to NW Azuay) and Peru.
A. b. allinornatus (Phelps, Sr & Phelps, Jr, 1949) – Sierra de San Luis (Falcón) and Sierra de Aroa (Yaracuy), in NW Venezuela.
A. b. inornatus (P. L. Sclater & Salvin, 1879) – SC Ecuador from SW Chimborazo S to NW Azuay (vicinity of R Chimbo and R Chachan).



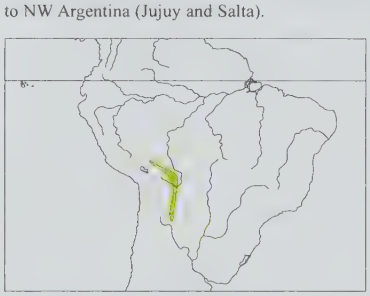
Descriptive notes. 16·3–19·5 cm; c. 32–47 g. Fairly large brush-finch. Nominate race has large black mask from forehead and forecrown down to gape and rearwards broadly around eye through ear-coverts to side of neck, small white supraloral spot, rest of crown and nape chestnut, becoming yellowish-tawny on side of crown; throat white (often puffed out), bordered below by narrow black pectoral band; upperparts olive-green, wing and tail darker olive, yellow bend of wing; underparts below breastband greyish, whiter on belly; iris dark brown to reddish-brown; bill black; legs dull blackish-brown. Sexes alike in coloration. Juvenile has cap sooty brown, upperparts dull greenish-brown to sooty brown, throat and breast dull sooty olive with heavy dusky streaking, upper mandible dull orange, base of lower mandible yellowish, tip dusky; pectoral band develops early, in Costa Rica (race *elsae*) in c. 2 months. Races differ mainly in plumage markings and coloration: *apertus* lacks (or nearly lacks) yellow supercilium, also lacks pectoral band, is greyish below, with white central line from chest down to vent; *suttoni* has brown of crown extending to mantle, yellow supercilium bold; *macrourus* is like nominate, but larger, longer-tailed and whiter below; *alleni* has pectoral band, but lacks supercilium; *elsae* is like nominate (although geographically distant), but has more black on crown, a narrow, short stripe on central forehead, and the yellow-tawny on side of crown reduced or absent, sometimes with strong olive-green tinge on flanks; *frontalis* has bill on average longer and thicker than in other races, three white marks on black frontal band, breastband variable; *inornatus* has irregular black marks on side of breast, lacks breastband, whitish below; *allinornatus* has all-white breast (no breastband), short bill, similar to previous but longer wing and tail. Voice. Song a jumble of high-pitched, slurred whistles and staccato notes, "peetee-zeer, peetee-súueet". Call a weak, high-pitched "pink", "seet" or "chink"; alarm of sharp, rapidly uttered notes.
Habitat. Thick undergrowth of dense tropical forest and thickets, at 400–3500 m; in Panama usually above 900 m. In Costa Rica found in epiphyte-laden subtropical forest, where seems to prefer thickest undergrowth; also in secondary forest in tangled lower growth. In Guatemala in temperate forests of oaks (*Quercus*) and other broadleaf trees, mixed with pines (*Pinus*), also in thick stands of "cypress" on some of the higher slopes, and at edges of corn fields; to 3050 m. Where sympatric with members of *A. torquatus* group, commonly found at lower elevations than latter; in some places the reverse, i.e. higher than *A. torquatus* group members.
Food and Feeding. Variety of insects and seeds. Forages on and near ground; hops on ground. Skulks. Turns over leaves to find food items, but does not scratch with feet. Sometimes follows army-ant (Formicidae) swarms. Often raises crown and throat feathers. Solitary and in pairs.
Breeding. In Mexico, laying mid-May to Jun and breeding Aug in Guerrero, breeding early Apr in C Oaxaca; fledglings in late Jul in Guatemala; nests in mid-Apr to Aug (most starting Apr) in Costa Rica; fledglings seen mid-Mar in Panamá; nesting Mar–Aug in Colombia. Nest a bulky, open cup of twigs and dry leaves, lined with finer materials such as rootlets and horsehair, placed below 2 m from ground in shrub or small dense tree. Clutch 2 eggs, sometimes only 1, white and unmarked; incubation by female, period 14 days; nestling period 13 days.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Status difficult to determine, as species skulks in dense undergrowth and is generally rather difficult to observe. Probably fairly common in appropriate habitat.
Bibliography. Armani (1985), Dickey & van Rossem (1938), Dunning (2008), Griscom (1932), Hilty (2003), Hilty & Brown (1986), Miller *et al.* (1957), Murray & Hardy (1981), Parkes (1959a), Remsen & Graves (1995b), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989), Ridgway (1901), Skutch (1967a), Stiles & Skutch (1989), Wetmore *et al.* (1984).

114. Green-striped Brush-finch

Arremon virenticeps

French: Tohi à raies vertes **German**: Grünscheitel-Buschammer **Spanish**: Cerquero Verdilistado

Taxonomy. *Buarremon virenticeps* Bonaparte, 1855, Mexico = Desierto de los Leones, near Mexico City, Distrito Federal, Mexico.
Sometimes placed in genus *Buarremon* or *Atlapetes*. Has sometimes been treated as conspecific with *A. torquatus*. Birds from Sinaloa described as race *verecundus*, but appear too poorly differentiated to warrant recognition. Monotypic.
Distribution. W Mexico in S Sinaloa, N Nayarit and S Durango, and from Jalisco and Colima E to W Puebla.



Descriptive notes. 18–20·5 cm; one male 41 g. Relatively large brush-finch. Has blackish head with white median stripe on forehead becoming greenish along midline of crown, short white supraloral stripe disconnected from long greenish to greenish-yellow stripe extending from above eye backwards onto nape; upperparts, including wings and tail, greyish-olive to olive-green; throat white; underparts grey, becoming whitish on belly and olive posteriorly; iris dark brown; bill dark grey; legs flesh-coloured to purplish-grey. Sexes similar in coloration. Juvenile has head blackish-brown with darker mask and indistinct paler stripes, upperparts, wings and tail brownish-olive, throat and underparts olive-brown, white mottling on throat, belly streaked buffy yellow. Voice. Song a variable, prolonged series of high, thin notes, "ssi ssi-ssi", etc. Call a thin, sharp "ssii".
Habitat. Undergrowth of humid montane evergreen forest and pine–oak (*Pinus–Quercus*) forest, at 1500–3500 m.
Food and Feeding. Little information; diet probably a variety of insect and plant food. Forages on and near ground. Singly and in pairs.
Breeding. Season Apr–Jun in Morelos, late Jun to early Aug in volcanic belt, and Jul on Pacific slope. Nest a deep cup of grasses, dried leaves and pine needles, lined with cattle hair and fine rootlets, well concealed 1–2 m up in vegetation. Clutch 2 eggs (Morelos). No further information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Sierra Madre Occidental and Trans-Mexican Range EBA. Status not well known. Apparently uncommon, but perhaps merely difficult to find.
Bibliography. Armani (1985), Dunning (2008), Howell & Webb (1995), Miller *et al.* (1957), Ridgway (1901), Rowley (1962).

115. White-browed Brush-finch

Arremon torquatus

French: Tohi à tête rayée **German**: Streifenkopf-Buschammer **Spanish**: Cerquero Cabecilistado
Other common names: Stripe-headed/Stripe-capped Brush-finch

Taxonomy. *Embernagra torquata* d'Orbigny and Lafresnaye, 1837, Carcuata, Yungas, Bolivia.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. costaricensis*, *A. atricapillus*, *A. basilicus*, *A. perijanus*, *A. assimilis*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Three subspecies currently recognized.
Subspecies and Distribution.
A. t. torquatus (d'Orbigny & Lafresnaye, 1837) – Andes of La Paz and W Cochabamba, in W Bolivia.
A. t. fimbriatus (Chapman, 1923) – Andes of E Cochabamba, W Santa Cruz and Chuquisaca, in SC Bolivia.
A. t. borellii (Salvadori, 1897) – lower elevations of Andes of S Bolivia (Chuquisaca and Tarija) S to NW Argentina (Jujuy and Salta).

Descriptive notes. 19 cm. Large brush-finch. Nominate race has white median stripe on forehead becoming grey along midline of crown, long white stripe extending from supraloral area back onto side of nape, broad blackish lateral crownstripe, broad blackish band from lores through ear-coverts; upperparts, including wings and tail, olive; throat white, conspicuous blackish chestband, whitish or light grey below, tinged with olive on flanks and side; iris dark brown; bill blackish; legs fleshy-brown to greyish. Sexes alike in coloration. Juvenile has dark parts of head sooty black, duller than on adult, upperparts olive-green, and is grey below, fading to dull buff on belly. Race *fimbriatus* similar to nominate but supraloral stripe reaches almost to base of bill, and chestband margined white; *borellii* lacks dark chestband. Voice. Song, from ground or low vegetation, a high-pitched sibilant series of whistles, lasting c. 3 seconds, e.g. "pze-zee-psee zaa sweee"; sometimes a longer more complex song, and sometimes short songs lasting 1·5 seconds spaced c. 1 second apart. Call a short sharp note.
Habitat. Occupies understorey in moist forest, also second growth and shrubby borders; 700–3050 m.
Food and Feeding. Little information on diet; probably insects and seeds. Forages on ground; usually rummages around in leaf litter, moving and flipping leaves with its bill. Generally occurs in singles and in pairs.

On following pages: 116. Costa Rican Brush-finch (*Arremon costaricensis*); 117. Black-headed Brush-finch (*Arremon atricapillus*); 118. Bangs's Brush-finch (*Arremon basilicus*); 119. Perija Brush-finch (*Arremon perijanus*); 120. Grey-browed Brush-finch (*Arremon assimilis*); 121. Caracas Brush-finch (*Arremon phaeopleurus*); 122. Paria Brush-finch (*Arremon phygas*); 123. Sooty-faced Finch (*Arremon crassirostris*); 124. Olive Finch (*Arremon castaneiceps*); 125. Tanager Finch (*Oreothraupis arremonops*); 126. Large-footed Finch (*Pezopetes capitalis*); 127. Yellow-thighed Finch (*Pselliophorus tibialis*); 128. Yellow-green Finch (*Pselliophorus luteoviridis*).

Breeding. Season Dec–Feb. Nest placed in dense shrub, usually within 2 m of ground. Clutch 2 eggs, white or palest blue; incubation by female, period 15·75 days (in NW Argentina); nestling period 12·75 days (NW Argentina).
Movements. Sedentary.
Status and Conservation. Not assessed. Uncommon to locally common. This species has a broad distribution, and appears to be generally common within its range; may even benefit from some forest disturbance.
Bibliography. Armani (1985), Auer *et al.* (2007), Cadena & Cuervo (2010), Canevari *et al.* (1991), Dunning (2008), Fjeldså & Krabbe (1990), Remsen & Graves (1995b), Ridgely & Tudor (1989).

116. **Costa Rican Brush-finch**

Arremon costaricensis

French: Tohi du Costa Rica **German**: Panamabuschammer **Spanish**: Cerquero Costarricense

Taxonomy. *Buarremon costaricensis* Bangs, 1907, Boruca, Costa Rica.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. atricapillus*, *A. basilicus*, *A. perijanus*, *A. assimilis*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Monotypic.
Distribution. Mountains of SW Costa Rica and adjacent W Panama (Chiriquí).

Descriptive notes. 17·4–20 cm; 40–49·5 g. Large brush-finch. Head is black, with broad grey median crownstripe and grey stripe extending from supraloral area back onto side of neck and nape; upperparts, wing and tail olive-green; throat, breast and belly white, becoming grey on sides and flanks, and olive-tinged on rear flanks, vent and undertail-coverts; iris dark reddish; bill dark grey; legs dark pink. Sexes alike. Juvenile has dark areas of head sooty black, duller than those of adult, upperparts olive-green, grey below, fading to dull buff on belly. Voice. Song high-pitched and thin, a relatively simple series of 1–3 alternated, distinct high-pitched phrases interspersed with silent periods. Call sharp and metallic.
Habitat. Undergrowth of dense, humid tropical forest and thickets, at 240–1500 m. Sometimes found in dense bamboo thickets, also sometimes at forest edge and openings close to dense vegetation.
Food and Feeding. Variety of insects and seeds; has been seen to eat decaying leaves. Forages on or near ground.
Breeding. Season Feb–Sept. Nest built by both sexes, a bulky open cup made from stems, vines, leaves and rootlets, lined with fine rootlets, fungal filaments and fibres stripped from leaves, placed 2–4 m (usually less than 3 m) up in dense vegetation such as vine thicket or tangle. Clutch 2 eggs; incubation carried out by female, period 15 days; chicks fed by both parents, nestling period 12 days.
Movements. Sedentary.
Status and Conservation. Not assessed. Status unclear; perhaps common in appropriate habitat, but difficult to find.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Ridgely & Gwynne (1989), Ridgway (1901), Stiles & Skutch (1989), Wetmore *et al.* (1984).

117. **Black-headed Brush-finch**

Arremon atricapillus

French: Tohi à tête noire **German**: Schwarzkopf-Buschammer **Spanish**: Cerquero Cabecinegro

Taxonomy. *Buarremon atricapillus* Lawrence, 1874, Bogotá, Colombia.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. basilicus*, *A. perijanus*, *A. assimilis*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Two subspecies currently recognized.
Subspecies and Distribution.
A. a. tacarcunae (Chapman, 1923) – E Panama (lower subtropical zone E from Panamá province).
A. a. atricapillus (Lawrence, 1874) – N Colombia in W, C & E Andes.

Descriptive notes. 19 cm; average 49·5 g. A stocky brush-finch looking relatively large-headed, and with longish bill; bill larger and thicker than those of other members of "*A. torquatus* complex". Nominate race has cap and face black (looks black-hooded), black ends discretely below cheek and ear-coverts and contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); below, white of throat extends to underparts, with grey on side of breast and greyish-olive flanks and vent; iris dark chestnut-brown; bill black; legs blackish. Sexes alike in coloration. Juvenile is dull greenish-olive above, slightly darker on head and dull brown on wings and tail, tawny below from throat to vent; adult plumage moults in patchy manner. Race *tacarcunae* has vague greyish median crownstripe and supercilium. Voice. Song a high-pitched series of rambling notes which proceed without breaks. Call a sharp note.
Habitat. Humid and wet forest and brushy borders, also dense old second growth. Favours dense undergrowth and edges in moist montane forest; likes thick and tangled habitat. Occurs at 500–1500 m.
Food and Feeding. Stomach contents insects, including ants (Formicidae) and beetles (Coleoptera), as well as seeds. Forages on ground, tending to keep under cover. Uses bill, not legs, to scratch at leaf litter. In pairs or singly.
Breeding. Season late Apr to Jun. No other information.
Movements. Sedentary.
Status and Conservation. Not assessed. Until recently was treated as a race of *A. torquatus*, and requires assessment. Uncommon and local, sometimes fairly common. Has a relatively small global range, but appears not to be under any particular large-scale threat.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Hilty & Brown (1986), Paynter (1978), Remsen & Graves (1995b), Ridgely & Gwynne (1989), Wetmore *et al.* (1984).

118. **Bangs's Brush-finch**

Arremon basilicus

French: Tohi de Bangs **German**: Bangsbuschammer **Spanish**: Cerquero de Bangs
Other common names: Colombian/Sierra Nevada Brush-finch

Taxonomy. *Buarremon basilicus* Bangs, 1898, Pueblo Viejo, 8000 feet [c. 2440 m], Magdalena, Colombia.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. atricapillus*, *A. perijanus*, *A. assimilis*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Monotypic.
Distribution. Santa Marta Mts, in N Colombia.

Descriptive notes. 19 cm. A stocky brush-finch looking relatively large-headed, and with longish bill. Has cap and face black, with grey median crownstripe and grey supercilium from above eye; black well demarcated below cheek and ear-coverts, not reaching back onto side of neck (as in closely related species) and contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); white of throat divided from white underparts by black pectoral band, otherwise side of breast grey and flanks to vent brownish-olive; iris dark chestnut-brown; bill black; legs blackish. Sexes alike in coloration. Juvenile is browner than adult above, head dusky and lacking striping, and is pale brownish with darker brown streaking below. Voice. Song a high-pitched sibilant series of notes, typical of "*A. torquatus* group", but with very fast delivery and almost nervous sound, this due also to inclusion of some quavering high-pitched whistles. Call a sharp note.
Habitat. Occupies undergrowth in humid montane forest, particularly near edges and borders; 600–2800 m.
Food and Feeding. Little information on diet. Forages on ground; tends to feed under cover of vegetation. Scratches at leaf litter with bill. In pairs and singly.
Breeding. Fledglings observed Mar–Jul. No other information.
Movements. Resident.
Status and Conservation. Not assessed. Until recently was treated as a race of *A. torquatus*, and requires assessment. Locally common. Has a relatively very small global range, but may be stable in terms of population numbers. In view of its small range, however, any potential threats need to identified.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Paynter (1978), Remsen & Graves (1995b), Restall *et al.* (2006), Todd & Carriker (1922).

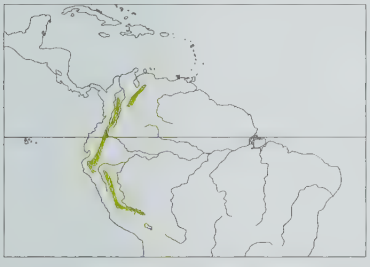
119. **Perija Brush-finch**

Arremon perijanus

French: Tohi de la Perija **German**: Perijábuschammer **Spanish**: Cerquero de Perijá
Other common names: Phelps's Brush-finch

Taxonomy. *Atlapetes torquatus perijanus* Phelps, Sr and Gilliard, 1940, La Sabana, 1200 m, Río Negro, Zulia, Venezuela. Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. atricapillus*, *A. basilicus*, *A. assimilis*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Monotypic.
Distribution. Perijá Mts, on N Colombia–W Venezuela border.

Descriptive notes. 19 cm. A stocky brush-finch looking relatively large-headed, and with longish bill. Has cap and face black, with grey median crownstripe and grey supercilium reaching nearly to bill base, both median crownstripe and supercilium becoming more whitish near bill, supercilium widening behind eye and meeting grey side of neck, grey colour extending down to side of breast; black ends discretely below cheek and ear-coverts, contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); white of throat separated from white underparts



by narrow and sometimes nearly broken black pectoral band, grey on side of breast passes on to greyish-cinnamon from flanks to vent; iris chestnut-brown to deep reddish; bill black; legs blackish. Sexes alike. Juvenile undescribed. Voice. No information.
Habitat. Occupies undergrowth in humid montane forest, particularly near edges and borders; 700–1800 m.
Food and Feeding. No details of diet. Forages on ground, using bill to scratch at leaf litter. In pairs and singly.
Breeding. Birds in breeding condition between Feb and Aug. No other information.
Movements. Resident.
Status and Conservation. Not assessed. Status not known. Until recently was treated as a race of *A. torquatus*, and requires assessment. Has relatively small global range. Any potential threats need to be identified.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Remsen & Graves (1995b), Restall *et al.* (2006).

120. Grey-browed Brush-finch

Arremon assimilis

French: Tohi à raies grises **German**: Schmalschnabel-Buschammer **Spanish**: Cerquero Picofino
Other common names: Grey-striped/Slender-billed Brush-finch

Taxonomy. *Tanagra assimilis* Boissonneau, 1840, Santa Fe de Bogotá, Colombia.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. atricapillus*, *A. basilicus*, *A. perijanus*, *A. phaeopleurus* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Four subspecies currently recognized.
Subspecies and Distribution.
A. a. larensis (Phelps, Sr & Phelps, Jr, 1949) – Andes of W Lara and W Táchira, in W Venezuela.
A. a. assimilis (Boissonneau, 1840) – Andes of Merida, in W Venezuela, and Colombia (all three ranges, but not W slope of W Andes; and S from Antioquia and Cundinamarca) S to Andes of NW Peru (Amazonas and Cajamarca).
A. a. nigrifrons (Chapman, 1923) – subtropical zone of Andes in SW Ecuador (El Oro and Loja) and NW Peru (Piura S to La Libertad).
A. a. poliophrys (Berlepsch & Stolzmann, 1896) – temperate zone of Andes in C & S Peru (Huánuco, Junín and Cuzco).

Descriptive notes. 19–20 cm. A stocky brush-finch which looks relatively large-headed, with longish bill. Nominate race has cap and face black, with grey median crownstripe and grey supercilium reaching nearly to bill base, both median crownstripe and supercilium becoming more whitish near bill, supercilium also widening behind eye and joining to grey side of neck, grey colour reaching down to side of breast; black ends discretely below cheek and ear-coverts, contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); underparts white, like throat, with grey side of breast extending to flanks and then onto greyish-olive vent; iris deep chestnut-brown; bill black; legs fleshy-pink to grey. Sexes alike. Juvenile is olive, with dusky cheeks and yellowish bill. Race *nigrifrons* has less extensive median crownstripe not reaching forehead, grey supercilium greatly reduced, almost absent behind eye; *larensis* has broad grey supercilium, becoming white in supraloral area, also has black pectoral band; *poliophrys* is similar to previous, also having black pectoral band, but with supercilium more extensive. Voice. Song a high, sibilant series of thin whistles with short spaces between separate phrases (often of three elements), e.g. "weseer-twee twesee? Sewtsee? Weseer-twee twesee? Sewtsee?...". Race *larensis* may intersperse nasal notes within high-pitched song. Call a high "ti" and a "tseer".
Habitat. Occupies humid montane forest, also forest edge and older second growth; occurs at elevations of 1500–3600 m.
Food and Feeding. No information on diet. Forages on ground; tends to scratch at leaf litter with its bill, not its feet. Singly and or in pairs.
Breeding. Fledglings recorded in Jun in Colombia (Cauca); in Ecuador in Aug (in NW), Jul (El Oro) and Sept (Loja), and in Peru in Aug (Amazonas), Jun (Huánuco) and Nov (Puno). No other information.
Movements. Resident.
Status and Conservation. Not assessed. Until recently was treated as a race of *A. torquatus*. Uncommon to locally common. Has a very large range within which it is generally reasonably widespread and numerous. No imminent threat to habitat or populations known.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Fjeldså & Krabbe (1990), Hilty (2003), Remsen & Graves (1995b), Schulenberg *et al.* (2007).

121. Caracas Brush-finch

Arremon phaeopleurus

French: Tohi de Sclater **German**: Sclaterbuschammer **Spanish**: Cerquero de Sclater
Other common names: Buffy-flanked/Sclater's Brush-finch

Taxonomy. *Buarremon phaeopleurus* P. L. Sclater, 1856, Caracas, Venezuela.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. atricapillus*, *A. basilicus*, *A. perijanus*, *A. assimilis* and *A. phygas*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Monotypic.
Distribution. Mountains of Aragua, Miranda and Distrito Federal, in N Venezuela.

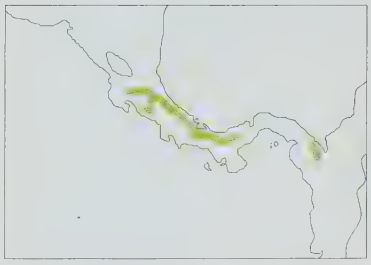
Descriptive notes. 19 cm. A stocky brush-finch which looks relatively large-headed, with longish bill. Has cap and face black, with grey median crownstripe and greyish-white supercilium that nearly reaches to bill base, both median crownstripe and supercilium becoming more whitish near bill, supercilium also widening behind eye and joining with grey neck side, grey colour extending down to side of breast; black ends discretely below cheek and ear-coverts, contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); white of throat separated from underparts by black breastband, with side of breast grey, flanks to vent olive-buff; iris chestnut-brown; bill black; legs dull fleshy to blackish. Sexes alike. Juvenile apparently undescribed. Voice. No information.
Habitat. Undergrowth in humid montane forest, particularly near edges and borders; 700–1800 m.
Food and Feeding. No information on diet. Forages on ground; scratches at leaf litter with its bill. Singly and in pairs.
Breeding. Season May–Jul. No other information.
Movements. Resident.
Status and Conservation. Not assessed. No information on status. Has relatively small global range, but may be stable in terms of numbers. Until recently was treated as a race of *A. torquatus*, and requires assessment; any potential threats need to be identified.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Hilty (2003), Paynter (1978), Restall *et al.* (2006).

122. Paria Brush-finch

Arremon phygas

French: Tohi de Berlepsch **German**: Berlepschbuschammer **Spanish**: Cerquero de Berlepsch
Other common names: Berlepsch's/Venezuelan Brush-finch

Taxonomy. *Buarremon torquatus phygas* Berlepsch, 1912, Los Palmares, Sucre, Venezuela.
Until recently was often placed in genus *Buarremon* (or *Atlapetes*), and considered conspecific with *A. torquatus*, *A. costaricensis*, *A. atricapillus*, *A. basilicus*, *A. perijanus*, *A. assimilis* and *A. phaeopleurus*. Recent molecular data indicated that this group was sister to present genus, while other *Buarremon* might be more closely related to another genus then used, *Lysurus*, rendering *Buarremon* polyphyletic; decision was therefore made, on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, to subsume *Buarremon* and *Lysurus* in present genus. In addition, molecular and morphological data indicated that all members of above-mentioned group should be treated as separate species. Monotypic.
Distribution. Mountains of N Anzoátegui, Sucre and N Monagas, in NE Venezuela.



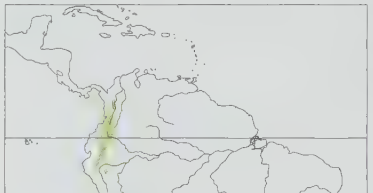
Descriptive notes. 19 cm. A stocky brush-finch looking relatively large-headed, with longish bill. Has cap and face black, vestigial trace of grey median crownstripe, and whitish rear supercilium that begins behind eye; neck side grey, this colour reaching down to side of breast; black ends discretely below cheek and ear-coverts, contrasting strongly with white throat; upperparts, including wings and tail, olive-green (looking more grass-green in good light); white throat separated from white underparts by black breastband, with side of breast and flanks grey, flanks with greenish tinge; iris deep chestnut-brown; bill black; legs blackish. Sexes alike. Juvenile is dusky olive above, darker on head, with indistinct pale olive supercilium, greyish-cinnamon with darker streaking below, slightly whiter throat, greyish lower mandible. Voice. Song described as a high-pitched and sibilant "éé-sit, ezzaweet...éé-sit...ezzaseet...ease-sit...tséé-a-teet..." that continues in rambling fashion without a clear break.
Habitat. Undergrowth in humid montane forest, particularly near edges and borders; 1000–1200 m.
Food and Feeding. No details of diet. Forages on ground, scratching at leaf litter with its bill. Singly and in pairs.
Breeding. Season May–Jul. No other information.
Movements. Resident.
Status and Conservation. Not assessed. Status not known. Until recently treated as a race of *A. torquatus*. Has small global range, but it may be stable in terms of numbers; any potential threats need to be identified.
Bibliography. Armani (1985), Cadena & Cuervo (2010), Hilty (2003), Paynter (1978), Restall *et al.* (2006).

123. Sooty-faced Finch

Arremon crassirostris

French: Tohi masqué **German**: Dickschnabel-Buschammer **Spanish**: Cerquero Carisucio
Other common names: Sooty-faced/Barranca Brush-finch, Barranca Finch

Taxonomy. *Buarremon crassirostris* Cassin, 1865, Barranca, Costa Rica.
Often placed in genus *Lysurus*; on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, this genus, and also, *Buarremon*, now subsumed in present genus. Probably forms a superspecies, and sometimes considered conspecific, with *A. castaneiceps*. Proposed race *eurous* (described from Cerro Tacarcuna, in E Panama), supposedly duller and with darker crown, known from only a single specimen; considered untenable. Monotypic.
Distribution. Mountains of C Costa Rica (Aguacate Mts) S through Panama (Bocas del Toro, Chiriquí, Veraguas, Coclé and E Darién) to adjacent W Colombia (Cerro Tacarcuna).
Descriptive notes. 15·0–17·1 cm; 37–40·5 g. Fairly large. Has crown rusty, side of face and throat blackish-grey, white submoustachial stripe; upperparts dark olive-green, upperwing and tail slightly browner; underparts mostly dark olive-green, lower breast and belly extensively yellow; iris dark brown or chocolate-brown; upper mandible dark grey, lower mandible pale yellow or whitish; legs dull flesh-coloured. Sexes alike in coloration. Juvenile is rich olive-brown above, with centre of



belly dull yellow, with blackish smudges. Voice. Song high-pitched, thin, emphatic "pseee-pséét"; also high-pitched, thin whistled "see see seeya sue sue sisi see". Call a sharp, thin, whistled "pu-pee".
Habitat. Dense, humid tropical forests and thickets, at 600–2340 m. Found in dense undergrowth in ravines and stream bottoms, or near wet forests in hilly areas.
Food and Feeding. Diet includes a variety of insects, spiders (Araneae), also berries. Forages on and near ground; hops over the ground, flicking wings and tail. Sometimes follows army ants (Formicidae).
Breeding. One nest found, in Costa Rica in May. Nest a domed structure with side entrance, made from moss, fern leaves and spike-moss (*Selaginella*), lined with bamboo leaves and fern rootlets, placed 1·5 m above ground and attached to fern stem, soft moss extending for 67 cm below the structure; contained 2 eggs, ivory-coloured with vinaceous-pink spots and speckles, spots concentrated at wide end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA and Darién Highlands EBA. Uncommon and local. Probably overlooked, as it is difficult to find.
Bibliography. Barrantes (1994a), Dunning (2008), Hilty & Brown (1986), Ridgely & Gwynne (1989), Ridgway (1901), Stiles & Skutch (1989), Wetmore *et al.* (1984).

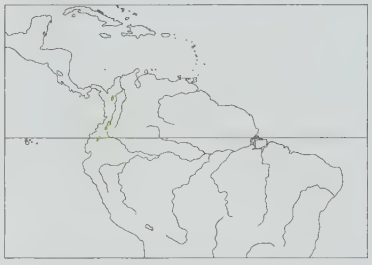
124. **Olive Finch**

Arremon castaneiceps

French: Tohi lysure **German**: Olivbuschammer **Spanish**: Cerquero Capirrufo
Other common names: Olive Brush-finch

Taxonomy. *Buarremon castaneiceps* P. L. Sclater, 1860, Río Napo, Ecuador.
Often placed in genus *Lysurus*; on basis of similarities in molecular data, plumage, voice, behaviour and micro-habitat, this genus, and also, *Buarremon*, now subsumed in present genus. Probably forms a superspecies, and sometimes considered conspecific, with *A. crassirostris*. Monotypic.
Distribution. W Andes of Colombia (W slope S from Antioquia, also E slope in Nariño) S on both slopes in Ecuador to Peru (to Cajamarca and Amazonas; also on E slope from Pasco S to Marcapata Valley, in Cuzco).

Descriptive notes. 15·5–16·5 cm; 34·5–39 g. A thickset, pot-bellied finch with relatively thick-based triangular bill. Face and throat to upper breast are dark grey, contrasting with rusty cap; rest of body, including upperparts, and lower breast to undertail-coverts, entirely olive-coloured and unstreaked; wing slightly darker, and tail blackish-grey with wide olive fringes and more olive central rectrices; iris dark brown; upper mandible dark grey, lower mandible pale grey; legs dusky. Sexes alike. Juvenile is similar to adult, but crown duller and face and throat olive, overall slightly more uneven-looking in general plumage colour than adult. Voice. Song a pleasant yet fast series of high-pitched sibilant whistles, duration more than 10 seconds, cascades up and down somewhat in pitch, but all notes quite high in frequency, individual notes rather strident in nature. Call a high, descending "tsew"; alarm call a chattering whistle, "tststststsi".
Habitat. Occupies dense understorey in humid lower montane forest, also vine tangles in ravines or at forest edge; fondness for habitat near streams, particularly mossy ravines. Occurs at elevations of 750–1800 m.
Food and Feeding. Poorly known. No details of diet. Forages at or near ground.
Breeding. Season mainly Mar–Apr in NE Ecuador (Napo). Twelve nests studied in Napo: nest is a large green ball of moss, rootlets and live fern leaves, with hooded side entrance opening into chamber lined with green fern leaves mixed with rootlets and dry strips of *Asplundia* (Cyclanthaceae) leaves, three were built on rock face and anchored to plants which supported base, remaining nine in vine tangle or supported by fine twigs in shrubbery. In another study, nest a fully domed structure with side entrance, made from mosses, lining of dry leaves, placed 1·5 m above a stream and attached to small ferns which secured it to a rock face on bank. Clutch 2 eggs, immaculate white in one study, in another (Napo) eggs white with red-brown speckling, sometimes concentrated at wide end. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Local and uncommon to rare. Rare to uncommon and local in Ecuador; rare and local in Peru. Possibly overlooked. Has a moderately sized global range, within which no evidence of any significant population declines.
Bibliography. Armani (1985), Cadena, Klicka & Ricklefs (2007), Greeney & Gelis (2006a), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg & Gill (1987), Schulenberg *et al.* (2007).



Genus *OREOTHRAUPIS* P. L. Sclater, 1856

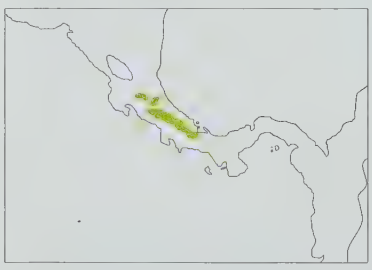
125. **Tanager Finch**

Oreothraupis arremonops

French: Tohi élégant **German**: Tangarenbuschammer **Spanish**: Cerquero Tangarino
Other common names: Finch-like Tanager

Taxonomy. *Saltator arremonops* P. L. Sclater, 1855, north of Quito, Ecuador.
Relationships unclear. Originally thought to be a saltator (*Saltator*) in the cardinal family (Cardinalidae) on basis of thick bill, and has been considered a tanager (Thraupidae), yet aspects of plumage, behaviour, voice and nesting suggest affiliation with *Atlapetes*. Monotypic.
Distribution. Very patchily in W Andes of Colombia (Antioquia, Valle del Cauca, Cauca and Nariño) and NW Ecuador (Imbabura and Pichincha).

Descriptive notes. 20–20·5 cm. A big bulky finch with pot-bellied structure, relatively short bill with curved culmen, and upper mandible sometimes overhanging lower. Head is black, broken by broad whitish-grey median crown-stripe and bold, wide whitish-grey stripe from above and just in front of eye extending backwards and broadening distinctly, terminating on rear side of neck; hindneck and entire upperparts to uppertail-coverts tawny with olive wash, upperwing and tail blackish with tawny edgings; chin and upper throat black, lower throat and underparts bright tawny, washed olive on flanks, with contrasting white belly patch that reaches forwards to lower breast in distinct V-shape; iris dark chestnut; bill black; legs dull brownish. Sexes alike. Juvenile is duller and browner than adult, brown above with dusky side of head, and with throat and belly partly yellow, breast olive and obscurely streaked. Voice. Song high-pitched and buzzy, starting with 3–5 more nasal notes before continuing as stilting chatter, "tzz tzz tzzz tz-zz-zz-tz tz tz tz tz tz", sounding stronger towards end; longer and more complex version given as duet. Call a high-pitched "tseet"; a frog-like "wert" also described.
Habitat. Undergrowth of montane forest, often mossy cloudforest; 1200–2700 m.
Food and Feeding. No information on diet. Forages on and near ground, usually in moist undergrowth, under low shrubs, in leaf litter of mossy forest; tends to be secretive. Often scratches at leaf litter. Generally in pairs or family groups.
Breeding. One nest with egg found in Nov and dependent juveniles in Nov and Dec in Ecuador (Pichincha), and juveniles with adults observed in Jun in Colombia (Cauca). Nest was cup-shaped, constructed largely from moss, with partial roof covering back half and a mossy lip at front, with an orchid (*Elleanthus tetrogeiton*) incorporated into the nest structure, placed c. 1 m above ground on a near-vertical bank; nest sheltered by roof of sticks and twigs, but unclear whether nest was built below roof or roof was constructed by the birds themselves. Nest contained 1 egg, bluish-white. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Chocó EBA. Rare and very local. Has fragmented range; known from only a handful of localities, and these generally under land-use pressures. Estimated global population in range 10,000–19,000 mature individuals; believed to be decreasing. In Colombia, population in Munchique National Park (Cauca) estimated at 1000 mature individuals. In Ecuador, modern records from Tandayapa area (Pichincha) and from Cotacachi–Cayapas National Park (Imbabura). Impression of rarity may be due in part to the inaccessibility of its habitat (wet, with steep slopes). Nevertheless, much habitat lost in recent decades. Human colonization following road-building, in Colombia especially the Cali–Buenaventura (Valle del Cauca) and Pasto–Tumaco (Nariño) highways, coupled with extensive logging concessions, have been main causes of habitat loss; further, deforestation rates increasing, primarily as a result of logging, human settlement, livestock grazing, cultivation of coca, and gold-mining. Although montane forests less threatened than those in lowlands, some habitat already lost, especially below 2000 m; rarely, areas of cloudforest illegally burnt, e.g. during severe drought, in order to provide grazable terrain. Occurs in a few protected areas, including Munchique and Farallones de Cali National Parks and Tambito and La Planada Nature Reserves (Colombia) and Cotacachi–Cayapas National Park and Mindo–Nambillo Protection Forest (Ecuador).
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Greeney *et al.* (1998), Lowen *et al.* (2000), Restall *et al.* (2006), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Stattersfield & Capper (2000), Storer (1958).



Genus *PEZOPETES* Cabanis, 1861

126. **Large-footed Finch**

Pezopetes capitalis

French: Tohi à grands pieds **German**: Großfuß-Buschammer **Spanish**: Cerquero Patigrande
Other common names: Big-footed Sparrow

Taxonomy. *Pezopetes capitalis* Cabanis, 1861, Costa Rica.
Genus sometimes subsumed in *Atlapetes*. Monotypic.
Distribution. Mountains of Costa Rica (Cordillera Central) S to extreme W Panama (W Bocas del Toro and W Chiriquí).

Descriptive notes. 17·4–20 cm; 55·8–55·9 g. A chunky, large, dark finch with rather slender bill, and large legs and feet. Forecrown, sides of crown, nape, thin postocular streak, and foreface to area around eye, malar area and throat dark charcoal, otherwise head and neck grey; upperparts darkish golden-olive, remiges and tail dusky grey with darkish golden-olive fringes, broadest on secondaries and tertials; underparts slightly paler golden-olive than back; iris mouse-brown or reddish; bill black; legs dull brownish to dusky or blackish. Sexes alike in coloration. Juvenile is buffy brown below, paler on centre of belly and breast; immature has grey of head replaced with dark olive, smudged with black, upperparts scaled black, underparts buff-olive, streaked black, flanks washed brown. Voice. Song, especially in Apr (less often in May, rarely after Jun) a medley of short, rich warbles and whistles, often with disjointed, dry trills, or a loud, high-pitched "pee pee pee pee", followed by lower "chu chu chu". Call a high, thin, soft "psee".

Habitat. Forest understorey, bamboo-choked ravines, open stands of bamboo under oaks (*Quercus*), second growth, and brushy pastures in high mountains. At 1500–3350 m, mostly above 3000 m.
Food and Feeding. Probably eats a variety of insects, spiders (Araneae), and worms; picks berries from shrubs (e.g. melastomes) and small trees. Forages on and near ground; hops, rather than walks. Searches in soil and leaf litter, using powerful two-foot scratches. In pairs throughout year.
Breeding. Season Mar–Jun, peaks in Mar–Apr. Nest built by one member of pair, presumably female, most material collected, all from ground, in immediate environs of nesting shrub; a loosely constructed cup of mosses, bamboo leaves and other plants, lined with finer pale-coloured grasses, often built on thick foundation of bamboo leaves or in dense bush, 0·3–2·5 m above ground. Clutch 1–2 eggs, most commonly 1 (rare within this family), whitish or pale blue with lilac spots or brownish marks, most heavily distributed at wide end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Common in Costa Rica in appropriate habitat; fairly common in highlands of W Chiriquí and adjacent Bocas del Toro, in Panama.
Bibliography. Armani (1985), Dunning (2008), Klein *et al.* (1991), Ridgely & Gwynne (1989), Ridgway (1901), Sassi (1939), Skutch (1967a), Stiles & Skutch (1989), Wetmore *et al.* (1984).

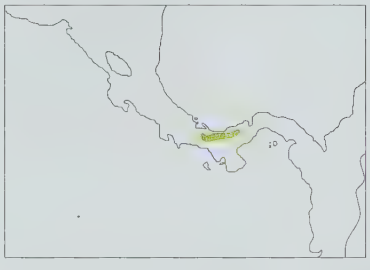
Genus *PSELLIOPHORUS* Ridgway, 1898

127. Yellow-thighed Finch

Pselliophorus tibialis

French: Tohi à cuisses jaunes **German**: Gelbschenkel-Buschammer **Spanish**: Cerquero Musliamarillo
Other common names: Yellow-thighed Sparrow/Sparrow-finch

Taxonomy. *Tachyphonus tibialis* Lawrence, 1864, San José, Costa Rica.
Genus sometimes subsumed in *Atlapetes*. Sometimes considered conspecific with *P. luteoviridis*. Monotypic.
Distribution. Mountains of Costa Rica (S from Cordillera de Tilarán) and extreme SW Panama (W Chiriquí).



Descriptive notes. 17–18·5 cm; 26·8–34·8 g. A medium-sized, slender dark finch with long tail and rather long, slender bill. Head is mostly dull black, except for slate-grey on rear ear-coverts to lower throat, sometimes extending to all of ear-coverts, cheek, chin and throat; can have a few whitish feathers, especially on upper eyelid and on side of forehead; upperparts slate-grey, with darker to blackish wings and tail; underparts slate-grey, sometimes with olive-green tinge, especially on breast; conspicuous swollen yellow thigh; iris dark brown to red-brown; bill black; legs flesh-coloured or dusky. Sexes alike in coloration. Juvenile is similar to adult, but duller above, tinged with brownish below, and thigh are dark grey. Voice. Song a short, breezy phrase in high, dry tone, "cheedle tweep sher tweeip", or "pitty me sweet sweet"; sometimes given by two birds together. Call a heavy metallic "tchuk" or "tchek", also an accelerated hard chatter.
Habitat. Humid forest, brushy openings, second growth, bamboo-choked ravines, and adjacent shady pastures; at 1200–1700 m.
Food and Feeding. Probably a variety of insects, spiders (Araneae) and berries, and nectar of tubular flowers. Feeds on and near ground, also higher, to treetops. Active and noisy. On the ground, often searches among litter for arthropods. Plucks small, white protein capsules (Müllerian bodies) from brown hairy bases of petioles of *Cecropia* leaves. Sometimes follows army ants (Formicidae). Found in pairs and family groups; joins mixed-species flocks, but does not gather in single-species flocks.
Breeding. Season Mar–May. Nest a bulky cup of straw, grass and dried bamboo leaves, lined with fine vegetable fibres or bamboo leaves, placed 0·7–4 m up in coarse grasses, bamboo or densely foliaged tree in wood or clearing. Clutch 2 eggs, white to palest blue with brown to lilac speckles or spots throughout; no information on incubation period; nestling period 12 days.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Common in Cordillera Central and Cordillera de Talamanca, and fairly common in the Cordillera de Tilarán, in Costa Rica. Common in highlands of W Chiriquí, in Panama.
Bibliography. Armani (1985), Dunning (2008), Ridgely & Gwynne (1989), Ridgway (1901), Sassi (1939), Skutch (1967a), Stiles & Skutch (1989), Wetmore *et al.* (1984).

128. Yellow-green Finch

Pselliophorus luteoviridis

French: Tohi jaune-vert **German**: Griscombuschammer **Spanish**: Cerquero Verdiamarillo
Other common names: Yellow-green Sparrow/Sparrow-finch

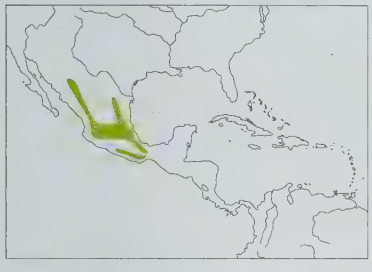
Taxonomy. *Pselliophorus luteoviridis* Griscom, 1924, Cerro Flores, 6000 feet [c. 1830 m], eastern Chiriquí, Panama.
Genus sometimes subsumed in *Atlapetes*. Sometimes considered conspecific with *P. tibialis*. Monotypic.
Distribution. Highlands of E Chiriquí and Veraguas, in WC Panama.

Descriptive notes. 17·2–18·5 cm. A medium-sized, slender dark finch with long tail. Head and throat are black, with dark slate-grey rear ear-coverts, yellowish-olive hindcollar; upperparts dark olive, becoming dullest towards rear; wing and tail blackish, bend of wing yellow; breast yellow-olive, darker olive below, only slightly paler than mantle; swollen yellow to orange-yellow thigh; iris dark brown to red-brown; bill black; legs flesh-coloured or dusky. Sexes alike in coloration. Juvenile apparently undescribed. Voice. Little information. Pairs or family groups give excited squeaky chatter-duet which incorporates sweet notes delivered in hurried manner, with tinkling quality; also "tsweet tsweet" calls.
Habitat. Highland cloudforest, borders and clearings, at 1200–1800 m.
Food and Feeding. Little known. Probably feeds on variety of arthropods and berries, taken on and near ground.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. VULNERABLE. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Little information. Probably scarce to locally fairly common; numbers thought to be decreasing. Estimated population 10,000–19,999 mature individuals. Has small global range, within which recorded at few localities. Range extends along the Serranía de Tabasará in Chiriquí and Veraguas, probably also reaching Bocas del Toro and Coclé. Has been recorded at Fortuna Forest Reserve, Cerro Flores and Cerro Colorado (adjacent peaks of Cerro Santiago massif), and above Santa Fe and Chitra (Cerro San Antonio), where scarce and poorly known. Main threat is habitat loss. Only isolated forest patches remain in E Chiriquí, and Serranía de Tabasará generally is threatened by clearance for coffee-growing, grazing, pesticides and fires; core area of the species' distribution, around Cerro Santiago (in Ngöbe-Buglé Indigenous Homeland), is suffering rapid deforestation associated with subsistence agriculture and cattle-rearing, and deforestation is now spreading to the higher elevations favoured by this species; habitat destruction occurs even within protected areas. Known to occur in Fortuna Forest Reserve (Chiriquí) and at W edge of Santa Fe National Park (Coclé); may occur also in Omar Torrijos Herrera National Park (Bocas del Toro).
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Ridgely & Gwynne (1989), Ridgway (1901), Stattersfield & Capper (2000), Wetmore *et al.* (1984).

PLATE 52

inches 3

cm 8



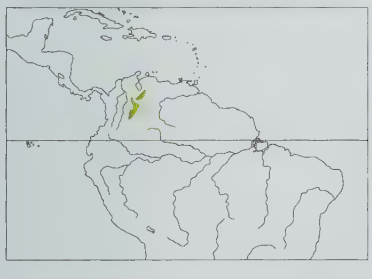
Genus *ATLAPETES* Wagler, 1831

129. Rufous-capped Brush-finch

Atlapetes pileatus

French: Tohi à calotte rousse **German**: Rotkappen-Buschammer **Spanish**: Atlapetes Coronirrufo
Other common names: Rufous-capped Sparrow

Taxonomy. *Atlapetes pileatus* Wagler, 1831, Mexico = state of Veracruz, Mexico.
Two subspecies recognized.
Subspecies and Distribution.
A. p. dilutus Ridgway, 1898 – N Mexican Plateau in SW Chihuahua, Durango, SE Coahuila, Nuevo León, SW Tamaulipas and San Luis Potosí.
A. p. pileatus Wagler, 1831 – S Mexican Plateau and S mountains from Sinaloa S to Michoacán, Guanajuato, Hidalgo and Veracruz, and in Guerrero, Oaxaca and Puebla.



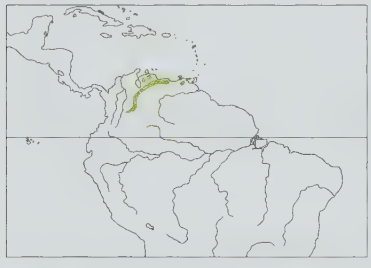
Descriptive notes. 14·5–16·5 cm; 21·5–27·5 g. Nominate race has crown rufous, side of face dark charcoal, nape and rest of head grey, throat broadly yellow; upperparts, including wings and tail, dull olive-green; underparts yellowish, olive tinge on side of breast, and usually more cinnamon on flanks and undertail-coverts; iris brown to dark red-brown; bill blackish; legs flesh-coloured to brownish. Sexes alike in coloration. Juvenile is like adult, but lacks rufous on crown, has pale wingbars, and is paler below. Race *dilutus* is paler in appearance and larger than nominate. Voice. Song 1–2 thin notes followed by 4 chipping notes, occasionally run into a trill. Call an excited "chik" or "chi-chi-chi-chi".
Habitat. Brush and undergrowth of humid pine–oak (*Pinus–Quercus*) belt of Mexican plateau, at 900–3500 m.
Food and Feeding. Variety of insects and seeds. Forages mainly on and near ground; also sometimes in bushes, keeping to tips of shrub branches. Hops on ground, and turns over leaves to find insects and other food items. Sometimes follows army-ant (Formicidae) swarms. Generally in pairs or small groups.
Breeding. Little known. Season Apr–Aug. Nest a cup made largely from dry grass, one in Morelos was placed c. 0·6 m above ground in dense vegetation. Clutch 2 eggs. No further information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common to fairly common in appropriate habitat. No known threats.
Bibliography. Armani (1985), Binford (1989), Dunning (2008), Howell & Webb (1995), Miller *et al.* (1957), Murray & Hardy (1981), Paynter (1978), Ridgway (1901), Rowley (1962), Sutton (1942), Urban (1959).

130. Moustached Brush-finch

Atlapetes albofrenatus

French: Tohi moustachu **German**: Weißbart-Buschammer **Spanish**: Atlapetes Bigotudo

Taxonomy. *Tanagra* (*Arremon*) *albo-frenatus* Boissonneau, 1840, Santa Fe de Bogotá, Colombia.
In Perijá Mts (NE Colombia–NW Venezuela border) there may be an undescribed taxon that is related to nominate race, intergrading with it in Norte de Santander; further study required. Two subspecies recognized.
Subspecies and Distribution.
A. a. albofrenatus (Boissonneau, 1840) – E Andes of Colombia from Norte de Santander S to Cundinamarca.
A. a. meridae (P. L. Sclater & Salvin, 1871) – Andes of Mérida and E Táchira, in W Venezuela.



Descriptive notes. 17·5 cm; average 30 g (nominate). A relatively large-headed brush-finch with long and somewhat droopy bill. Nominate race has boldly patterned head, with rufous cap from forehead to nape, contrasting black mask, and bright white submoustachial stripe bordered below by black malar stripe, which in turn borders clean white throat; upperparts, including wings and tail, olive-green; underparts lemon-yellow, cleaner in centre, more tinged olive on sides and flanks; iris chestnut to deep red or dark brown; bill black; legs brownish to fleshy-grey. Sexes alike. Juvenile is olive above, dusky yellowish below, moustachial area dull yellow, malar stripe weakly formed, also mask duller blackish, and crown olive, rather than chestnut; in fresh plumage marginally paler tips of upperwing-coverts, forming two obscure wingbars. Race *meridae* has yellow throat and brighter, cleaner yellow underparts, malar stripe narrower or absent. Voice. Song variable, usually two parts, starting with musical set of notes and then a longer, faster series of clattering notes, "czeet czeet czeet czeet tswit-tswit-tswit-tsu-tsu-tsu-tsu-tsu-tsu"; some songs shorter, with several introductory whistles and then a slightly lower-pitched trill; also a duet, high-pitched and rollicking, with quavering quality that is distinctive. Call a high "ptiip", often repeated; also a nasal "bzzzp".
Habitat. Shrubby borders and undergrowth of humid subtropical forest, regenerating clearings, and thick growth along roads; quite tolerant of disturbed habitats. Sometimes edges of drier woodland, but where thick undergrowth present. Mostly at 1500–2500 m; down to 1000 m in Colombia.
Food and Feeding. Food includes arthropods, fruits and berries. Forages in trees and shrubs, as well as on ground. Usually in pairs or family parties.
Breeding. Fledglings found in Venezuela during May and Jun. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cordillera de Mérida EBA and Colombian East Andes EBA. Fairly common. Has fairly extensive range, within which no evidence of any significant declines in populations.
Bibliography. Armani (1985), Hilty (2003), Hilty & Brown (1986), Paynter (1978), Ridgely & Tudor (1989).

131. Ochre-breasted Brush-finch

Atlapetes semirufus

French: Tohi demi-roux **German**: Ockerbrust-Buschammer **Spanish**: Atlapetes Semirrufo

Taxonomy. *Tanagra* (*Arremon*) *semirufus* Boissonneau, 1840, Santa Fe de Bogotá, Colombia.
Sometimes considered to form a superspecies with *A. personatus* and *A. fulviceps*; likely closely related to former, but latter may not belong in such a group. Six subspecies recognized.
Subspecies and Distribution.
A. s. benedettii Phelps, Sr & Gilliard, 1941 – mountains of Falcón, Lara and Trujillo, in NW Venezuela.
A. s. denisei (Hellmayr, 1911) – N & NE Venezuela (Carabobo and Aragua E to Monagas and Sucre).
A. s. albigula J. T. Zimmer & Phelps, Sr, 1946 – N Táchira, in W Venezuela.
A. s. zimmeri Meyer de Schauensee, 1947 – E slope of E Andes of Colombia (S Norte de Santander and NE Boyacá) and Venezuela (W Táchira).
A. s. majusculus Todd, 1919 –E slope of E Andes in N Boyacá (Colombia).
A. s. semirufus (Boissonneau, 1840) – E slope of E Andes in Cundinamarca (Colombia).

Descriptive notes. 18 cm; 29–33 g. A slim brush-finch with finely tipped and pointed bill. Nominate race has head to nape and down to breast plain tawny-orange; upperparts, including wings and tail, olive; underparts below breast yellowish, washed greenish on flanks, and yellow on undertail-coverts; iris chestnut; bill grey; legs pinkish to dusky grey. Sexes alike. Juvenile is brownish-olive above, including head, dull yellowish below, with olive chest and narrow dark streaking from breast to undertail-coverts, also often shows darker malar stripe; older immature intermediate between juvenile and adult, with tawny appearing patchily on face, and breast becoming fully tawny early on. Race *benedettii* is like nominate, but paler orange on breast, brighter greenish on flanks, juvenile dark and with wide, bold malar stripe; *denisei* is much more colour-saturated than nominate, deeper orange-tawny on head, darker olive on flanks, olive colour extending to undertail-coverts; *albigula* is paler orange on head, white on centre of throat, otherwise mostly pale yellowish below, with tawny wash on side of breast, cinnamon undertail-coverts, juvenile with pinkish bill and rather pale and nearly unstreaked below; *majusculus* has paler head and bill than nominate, whitish wash on ear-coverts and throat, undertail-coverts yellowish; *zimmeri* is like previous, but washed pale tawny on undertail-coverts and with darker bill. Voice. Song, early in morning largely during start of rainy season, a rapid "wheet-wheet, tsu-tsu-tsu" or "pi-pit, chew chew chew!".
Habitat. Shrubbery and understorey in forest borders, also secondary growth such as regenerating clearings. At 1000–2500 m in Venezuela; 2000–3500 m in Colombia.
Food and Feeding. Seeds and arthropods, also berries and small fruits. Forages on and near ground, under dense understorey; also in shrubs and small trees. On forest floor often uses bill to flick at leaves, looking for seeds and arthropods. Found in pairs and in small groups, perhaps family parties.
Breeding. Season Mar–Jul (spanning end of dry season and first half of rainy season), with peak Apr to late May. Nest built by female, a cup constructed from thick grasses, at times some small sticks on perimeter, lining of thin grasses and rootlets, usually placed 0·2–3 m from ground and concealed in grass, vine or bush, often at edge of clearing or trail. Clutch typically 2 eggs, whitish with reddish-brown spots, which are concentrated around large end; incubation by female, period 14–15 days; nestling period 10·5 days. In one study, nest failure found to be due essentially to predation of nest contents.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon in Colombia; fairly common in Venezuela. Has reasonably broad range, within which no evidence of any significant population declines or threats to habitat.
Bibliography. Armani (1985), Biancucci & Martin (2008), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Paynter (1978), Restall *et al.* (2006), Ridgely & Tudor (1989).

132. Tepui Brush-finch

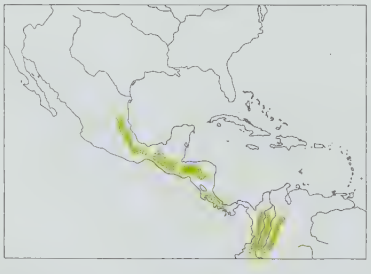
Atlapetes personatus

French: Tohi des tépuis **German**: Tepuibuschammer **Spanish**: Atlapetes de Tepuí

Taxonomy. *Arremon personatus* Cabanis, 1848, Roraima, 6500 feet [c. 1980 m], Venezuela.
Sometimes considered to form a superspecies with *A. semirufus* and *A. fulviceps*; likely closely related to former, but latter may not belong in such a group. Six subspecies recognized.
Subspecies and Distribution.
A. p. paraquensis Phelps, Sr & Phelps, Jr, 1946 – Cerro Paraque and Cerro Yavi, in NW & NE Amazonas (S Venezuela).
A. p. parui Phelps, Sr & Phelps, Jr, 1950 – Cerro Parú, in NC Amazonas (S Venezuela).
A. p. duidae Chapman, 1929 – tepui region of S Venezuela, in C Amazonas (Mt Duida) and WC Bolívar (Mt Guaiquinima).

On following pages: 133. White-naped Brush-finch (*Atlapetes albinucha*); 134. Santa Marta Brush-finch (*Atlapetes melanocephalus*); 135. Pale-naped Brush-finch (*Atlapetes pallidinucha*); 136. Yellow-headed Brush-finch (*Atlapetes flaviceps*); 137. Dusky-headed Brush-finch (*Atlapetes fuscoolivaceus*); 138. Tricolored Brush-finch (*Atlapetes tricolor*); 139. White-rimmed Brush-finch (*Atlapetes leucopis*); 140. Yellow-breasted Brush-finch (*Atlapetes latinuchus*).

A. p. jugularis Phelps, Sr & Phelps, Jr, 1955 – Cerro La Neblina in S Venezuela (SE Amazonas) and adjacent N Brazil (Amazonas).
A. p. collaris Chapman, 1939 – Mt Auyan-tepui, in SE Bolívar (SE Venezuela).
A. p. personatus (Cabanis, 1848) – Mt Roraima and nearby tepuis of SE Bolívar, in SE Venezuela.

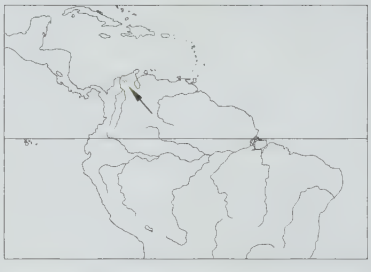


Descriptive notes. 18 cm; 29–37 g. A stocky brush-finch with long bill with slightly curved culmen. Nominate race has head to nape plain cinnamon-rufous; upperparts olive, upperwing and tail similarly coloured, but slightly more blackish; rufous head coloration stops abruptly below malar area and contrasts with yellow throat; underparts from breast to lower belly yellow, flanks, vent and undertail-coverts dusky olive; iris chestnut; bill black; legs dusky pink. Sexes alike. Juvenile is slightly browner above, most notably with brownish-grey head; rufous colour begins to appear at early stage in patchy manner. Races differ mainly in extent of rufous on head to breast: *collaris* similar to nominate but gular yellow tends to be more restricted to central throat, collar of olive or rusty streaking on breast, juvenile very dark brown above, buffy tawny with extensive streaking below; *duidae* has entire head to breast rufous, is more deeply colour-saturated and darker olive on flanks and vent, upperparts darker, juvenile reddish-brown above and dull yellowish with brown streaking below; *jugularis* has entire head and throat rufous, but extensively yellow below, with little olive wash on flanks, juvenile pale brownish above and only slightly streaked below; *paraquensis* has forehead and chin blackish, rufous on throat (not extending to breast), pale olive wash on flanks and vent, juvenile pale brown above and unstreaked pale buffy yellow below; *parui* is dark, heavily colour-saturated, and rufous extends to throat and breast, belly deep yellow, flanks and undertail-coverts dark olive, latter fringed with bright yellow. Voice. Usually rather quiet. Song, mostly at dawn, quick and sweet-sounding, from a simple "tweet swee-tee-tee-tee" to a more complex "speek! speek! speeu-téé-tu'tu'tu"; also, in duet, a rather mechanical sounding trilling chatter, starts with more widely spaced notes and blends into a trill.
Habitat. Shrubby borders and clearings, also understorey in closed wet forest in tepuis; also young as well as old second growth, particularly when associated with white sandy soil. At 1000–2500 m.
Food and Feeding. Little information. Diet arthropods and berries (often melastomes). Forages close to ground, typically cocking or flipping up tail as it does so. Sometimes drops to forage on ground, seeking insect prey and berries in shrubbery. Found in pairs and in family groups of up to four individuals.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Locally very common. Range very fragmented. Although patchy in its distribution, there is no evidence of significant declines in its numbers.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Paynter (1978), Restall *et al.* (2006), Ridgely & Tudor (1989), Willard *et al.* (1991).

133. White-naped Brush-finch
Atlapetes albinucha

French: Tohi à calotte blanche **Spanish**: Atlapetes Nuquiblanco
German: Weißnacken-Buschammer
Other common names: White-naped Atlapetes; Yellow-throated Brush-finch/Sparrow ("*gutturalis* group")

Taxonomy. *Embernagra albinucha* d'Orbigny and Lafresnaye, 1838, Cartagena; error = Caribbean slope of Mexico.
Often placed in genus *Buarremon* or *Arremon*. Races form two groups, the "*albinucha* group" (nominate and *griseipectus*) and "*gutturalis* group" (remaining races); these often treated as two separate species, but differences between them appear to be insufficient to justify such treatment. Race *fuscipygius* appears to intergrade with *griseipectus* in NW El Salvador. Poorly differentiated race *coloratus* possibly better merged with *brunnescens*. Eight subspecies recognized.
Subspecies and Distribution.
A. a. albinucha (d'Orbigny & Lafresnaye, 1838) – Caribbean slope of Mexico from Puebla and Veracruz S to Oaxaca and Chiapas.
A. a. griseipectus Dwight & Griscom, 1921 – Pacific slope of SW Chiapas (S Mexico), highlands of W Guatemala and El Salvador (San José del Sacre and Volcán de Santa Ana).
A. a. fuscipygius Dwight & Griscom, 1921 – highlands of Honduras, NW El Salvador (Los Esesmiles) and NW Nicaragua.
A. a. parvirostris Dwight & Griscom, 1921 – subtropical zone of Costa Rica.
A. a. brunnescens Chapman, 1915 – subtropical zone of W Panama (W Chiriquí).
A. a. coloratus Griscom, 1924 – subtropical zone of E Chiriquí (Panama).
A. a. azuerensis Aldrich, 1937 – Azuero Peninsula, in S Panama.
A. a. gutturalis (Lafresnaye, 1843) – upper tropical and subtropical zones of Colombian Andes S from Antioquia, Santander and Norte de Santander.

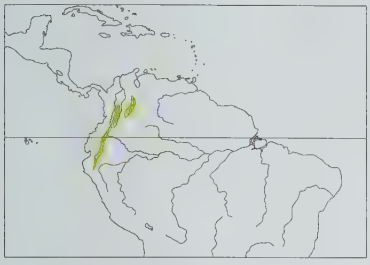


Descriptive notes. 17–21 cm; 31–37·2 g. Nominate race has black head with broad white median crownstripe; upperparts, including wings and tail, dark slaty grey with slight olive tinge; throat and underparts yellow, flanks washed dusky yellowish-grey; iris red-brown to dark brown; bill blackish; legs flesh-coloured to dark grey-brown. Sexes similar. Juvenile is like adult, but dark sooty brown above, blacker on head, yellow below, throat brightest, contrasting with dark-streaked breast, flanks tinged brownish-cinnamon. Races differ mainly in size, colour tones and pattern of underparts, nominate the only one all yellow below: *griseipectus* is lighter-coloured and more olive above than nominate, throat to uppermost breast light yellow, breast grey; *fuscipygius* is brownest of all races, median crownstripe narrow like *brunnescens*; *gutturalis* is larger and larger-billed than other races, yellow on throat, whitish on breast and underparts, with flanks and vent olive-grey; *parvirostris* is like previous, but smaller, with smaller bill, upperparts darker grey, throat paler yellow; *brunnescens* is browner than *gutturalis*, with crownstripe narrower, flanks and vent buffy brown; *coloratus* is like previous, but throat deeper yellow (sometimes orange-tinged); *azuerensis* is dark brown (not greyish) above, has blackish remiges edged reddish-brown, grey band on breast, reddish-brown flanks and vent. Voice. Song a deliberate series of notes, "tsee tseea tseea tseea tseer", sometimes transliterated as "o see, I'm weary, pity me".
Habitat. Thick undergrowth, shrubby clearings, openings in cloudforest, and borders of dense tropical forests and thickets, at 1200–3150 m. In Guatemala in temperate forests of oaks (*Quercus*) and other broadleaf trees, mixed with pines (*Pinus*), also in thick stands of "cypress" on some higher slopes. In El Salvador found in upper tropical zones, 1950–2600 m, at edges of clearings in cloudforest; recorded in pines and bracken (*Pteridium*). In Costa Rica in epiphyte-laden subtropical forest, where seems to prefer thickest undergrowth. Occurs also in tangled lower growth in secondary forest. In Colombia also in forest borders with dense shrubs and in thickets, sometimes along roadsides.
Food and Feeding. Variety of insects and seeds. Forages on and near ground. Hops on ground; turns over leaves to find insects and other foods. Sometimes follows army-ant (Formicidae) swarms. Found singly or in pairs.
Breeding. Nesting recorded in late Apr in S Mexico (Oaxaca), Apr–Jul in Costa Rica and Panama, and Mar–Sept in Colombia. Nest is an open bulky cup of twigs, dry grass and leaves, lined with pine needles and other finer materials, placed 0·6–3 m up in dense vegetation (e.g. clipped bamboo), or sometimes on ground. Clutch 2 or 3 eggs, rarely only 1, white and unmarked. No further information available.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common to fairly common in Mexico; common in appropriate habitat in El Salvador, Costa Rica and W & S Panama; fairly common in Colombia. In Mexico, reports of nominate race also from Valley of Mexico and San Luis Potosí considered doubtful. No known threats.
Bibliography. Armani (1985), Binford (1989), Dickey & van Rossem (1938), Dunning (2008), Dwight & Griscom (1921), Griscom (1924, 1932), Hilty & Brown (1986), Land (1970), Monroe (1968), Palacios (2005), Paynter (1964b), Ridgely & Tudor (1989), Ridgway (1901), Stiles & Skutch (1989), Wetmore *et al.* (1984).

134. Santa Marta Brush-finch
Atlapetes melanocephalus

French: Tohi des Santa Marta **Spanish**: Atlapetes de Santa Marta
German: Grauohr-Buschammer

Taxonomy. *Buarremon melanocephalus* Salvin and Godman, 1880, San Sebastian, Colombia.
Monotypic.
Distribution. Santa Marta Mts (Magdalena, César and Guajira), in N Colombia.



Descriptive notes. 17 cm; average 25 g. A large-bodied brush-finch with large and rounded head, relatively thick-based bill. Head to chin and malar region is black except for variable grey ear-coverts, creating pale-cheeked look; upperparts olive, upperwing and tail blackish with olive edgings; throat to undertail-coverts lemon-yellow, flanks washed olive mixed with grey; iris red-brown to dark brown; bill black; legs blackish. Sexes alike. Juvenile is similar to adult, but pale cheek patch obscured, dull yellowish with fine dark streaks below. Voice. Song loud and cascading, usually given as duet with a lot of buzzy notes, "bzt-bzt-bzt, bzbzbzbzbzzbzbzbzbz", speeding up and becoming louder towards end. Call a high nasal "bzzt...bzzt...bzzt", repeated at regular intervals.
Habitat. Shrubbery and forest borders within humid subtropical forest, also second growth and overgrown brushy pastures; absent from interior of mature forest. At 1000–3000 m.
Food and Feeding. Few data on diet. Forages in and near ground, in or beneath thickets; may forage also as high as 10 m from ground, but usually below eye level. Often accompanies mixed-species foraging flocks.
Breeding. Birds in breeding condition in Jan–Apr, and fledglings recorded Nov–Jun. Nest reported as a domed structure. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Santa Marta Mountains EBA. Common within its small area of distribution. Has a small range, but because of its apparent abundance and lack of any known population-level declines it is considered not to be at risk.
Bibliography. Fjeldså & Krabbe (1990), Hilty & Brown (1986), Restall *et al.* (2006), Ridgely & Tudor (1989), Todd & Carriker (1922).

135. Pale-naped Brush-finch
Atlapetes pallidinucha

French: Tohi à nuque claire **German**: Zimtstirn-Buschammer **Spanish**: Atlapetes Nuquipálido

Taxonomy. *Tanagra* (*Arremon*) *pallidinucha* Boissonneau, 1840, Santa Fe de Bogotá, Colombia.
Two subspecies recognized.
Subspecies and Distribution.
A. p. pallidinucha (Boissonneau, 1840) – SW Venezuela (Táchira) and E Andes of Colombia (Norte de Santander S to Cundinamarca).
A. p. papallactae Hellmayr, 1913 – C Andes of Colombia (S from Caldas) and E slope of Ecuador S to extreme N Peru (Piura–Cajamarca border).
Descriptive notes. 18 cm; 21·4–40·2 g. A relatively large-headed brush-finch with high rounded crown, and relatively thick but short and pointed bill. Nominate race has broad pale cinnamon central stripe from forehead to mid-crown, becoming white on hindcrown and nape, contrasting with black side of head; upperparts dark slate-grey, upperwing and tail blackish; throat bright yellow, this colour extending to breast and belly, washed olivaceous to grey on sides, flanks and undertail-coverts; iris dark chestnut; bill black; legs pinkish-dusky. Sexes alike. Juvenile is duller than adult, washed brownish above, narrowly streaked on crown, and streaked dusky on breast. Race *papallactae* has forehead very pale cinnamon or yellow, and olivaceous to grey wash of

underparts extends to breast, isolating yellow throat, juvenile browner and with darker underparts than nominate. Voice. Territorial song in N Peru noted as a musical and whistled "wheet-tew-tew-tew"; one vocalization a rapidly delivered cacophony of sweet, strident, buzzy and high notes, and single individuals give slightly slower song reminiscent of a siskin (*Carduelis*) owing to frequent repetition of notes; chatter-duet more complex, very hard to describe, mixes notes of various types in quick succession. Call a high-pitched soft "tip"; also a nasal "pffe", repeated several times.

Habitat. Subtropical to temperate zone in borders and understorey of humid forest, most often at or near tree-line; often in stunted shrubby second growth, elfin forest and shrubs. Occurs also in interior of temperate forest, where has preference for bamboo thickets. At 2800–3600 m.

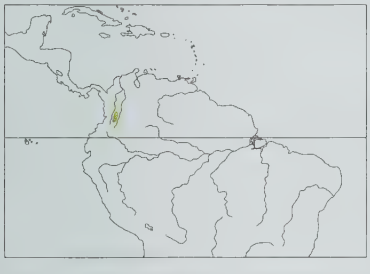
Food and Feeding. Berries, such as those of *Miconia* or Ericaceae; also insects. Stomach contents have included seeds and other plant material, as well as insects. Tends to forage on ground or near ground, concealed in dense understorey and edges of thickets; often in shrubbery close to the ground. In pairs and family groups; often joins mixed-species foraging flocks.

Breeding. In Colombia, nest found in Sept in Bogotá, birds in breeding condition Feb–Sept in C & E Andes, and fledglings found in Mar and Jun; fledglings in Nov in Ecuador (Pichincha). One nest found, a bulky cup mostly of dry twigs and grasses, base covered with mosses, some dry leaves of *Chusquea* bamboo attached around outside, lining of tightly interwoven thin dry grass leaves, external diameter 12 cm, height 10 cm, internal diameter 6·5 cm, depth 6 cm; placed 40 cm above ground in dense thicket of grasses, supported by tall grasses (1·5 m) and one bamboo stem, these creating roof-like covering. Nest contained 1 egg, pale greenish-blue with brownish-ochre and dark lilac spots and blotches, these concentrated around larger end; egg was being incubated. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common; usually most common at higher elevations, above 3000 m. Has reasonably large range, high abundance in parts of that range, and no evidence of widespread habitat problems or significant population declines.

Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Parker *et al.* (1985), Peraza (2009), Restall *et al.* (2006), Ridgely & Tudor (1989), Stiles *et al.* (2000).



136. **Yellow-headed Brush-finch**

Atlapetes flaviceps

French: Tohi à tête olive **German**: Goldkopf-Buschammer **Spanish**: Atlapetes Cabecigualdo
Other common names: Olive-headed Brush-finch

Taxonomy. *Atlapetes flaviceps* Chapman, 1912, River Toche, 6800 feet [c. 2070 m], Tolima, Colombia.
Monotypic.

Distribution. E slope of C Andes in N Tolima, in Colombia.

Descriptive notes. 17 cm. A relatively short-billed brush-finch with large head and distinctly graduated tail; crown feathers often raised, giving round-headed appearance, and bill has even curve to culmen and gonys, making it look relatively blunt. Has head entirely yellowish, grizzled with olive on crown and face (amount of olive wash varies individually, and possibly related to age); supercilium and submoustachial stripe cleaner yellow, yellow extending to nape and back of head; upperparts, including upperwing-coverts, olive, flight-feathers and tail blackish; throat to undertail-coverts bright yellow, flanks washed olive; iris dark reddish-brown; bill blackish; legs dusky brown. Sexes alike. Juvenile has strong olive wash on head, breast and flanks. Voice. Song lasts 1·5–2 seconds, has two parts, some introductory notes and then a trilled end, "tseep-tseep-tseetp, twtitititititit", another variation "chweet-twee, to-tee-tee-tee". Partners also duet, with much longer song (5–9 seconds) with many stuttering trills and chatters, and less "clean" sound as two birds singing on top of each other and not entirely in synchrony. Call a high-pitched "tsiip", repeated at even intervals; also louder and harsher "szeeet".

Habitat. Brush adjacent to cleared areas on mountainsides, also in undergrowth within moist montane forest; will accept second growth, borders and edges of plantations and fruit orchards, as well as forest fragments. At 1900–2440 m.

Food and Feeding. Takes small fruits, insects and seeds. Fairly arboreal. Forages mostly in pairs, sometimes in small groups of up to four individuals; will join mixed-species foraging flocks with various tanagers (Thraupidae) and Golden-fronted Whitestart (*Myioborus ornatus*).

Breeding. Juveniles with parents observed in Jun, and collection of nesting material in Nov. No other information.

Movements. Thought to be resident; present all year at known sites.

Status and Conservation. ENDANGERED. Restricted-range species: present in Colombian Inter-Andean Slopes EBA. Has a very small range and very small global population, estimated at 680 mature individuals. Numbers thought to be in continuing slow decline owing to rates of habitat loss. For a long time was known from only three specimens, all from type locality in the Toche Valley (Tolima); in 1967 was captured at a second site, in La Plata Vieja Valley (in Huila). For many decades little else was known about this species, but it is now known to be locally common at type locality. No further records from the Huila locality. Continuing habitat degradation is occurring within its range.

Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), Chapman (1912), Hilty & Brown (1986), Losada-Prado *et al.* (2005), Restall *et al.* (2006), Ridgely & Tudor (1989), Stattersfield & Capper (2000).

137. **Dusky-headed Brush-finch**

Atlapetes fuscoolivaceus

French: Tohi sombre **German**: Rußkopf-Buschammer **Spanish**: Atlapetes Sombrío

Taxonomy. *Atlapetes fusco-olivaceus* Chapman, 1914, San Agustín, 5000 feet [c. 1520 m], Huila, Colombia.
Monotypic.

Distribution. Upper Magdalena Valley (in Huila), in SW Colombia.

Descriptive notes. 17–18 cm; two males average 32·5 g. A dull-coloured brush-finch with distinctly graduated tail. Has crown down to lores, cheek and ear-coverts dusky olive, often nearing blackish on side of face, contrasting yellow submoustachial area, this in turn highlighted by narrow dark malar stripe; nape and upperparts similarly olive-dusky, slightly brighter olive on rump, and upperwing and tail slightly darker, flight-feathers with fine olive edging; throat and underparts yellow, becoming olive-washed on breast and flanks; iris reddish to deep brown; bill black; legs dusky brown. Sexes similar. Juvenile is similar to adult, but lacks blackish on face, is obscurely streaked below, and yellow submoustachial stripe is washed olive. Voice. Song a short and quickly delivered series lasting c. 1 second, "swee-see chipi", with springy and bouncy nature; chatter-duet a multi-parted series of chips, trills and other repeated notes, e.g. "ti-ti-ti-ti-ti-ti, tch-tch-tch-tch-tch, chew chew chew", lower-pitched and slower towards end. Call a high "seep".

Habitat. Humid forest edge, in shrubbery and understorey, also low second growth and clearings with dense shrub component such as overgrown pastures; not common inside forest, and if present usually near a treefall gap, or tangled opening. At 1600–2400 m.

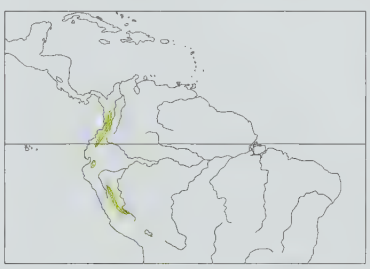
Food and Feeding. Little information on diet. Relatively arboreal, but forages also on ground; foraging strata mainly 0·5–6 m above ground. Much foraging is through dense thickets, and moves quickly through, pecking and probing rapidly in search of food. Usually in pairs or small groups.

Breeding. Birds in breeding condition in Feb–Apr in S Huila. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Colombian Inter-Andean Slopes EBA. Fairly common to common. Has small global range, and likely to be declining moderately rapidly as a result of habitat loss and degradation. Tolerant of some degree of degradation of habitat, and able to survive, at least temporarily, in second growth and degraded forest. Study of this species' ecology needed in order to determine its precise habitat requirements and any potential threats.

Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), Chapman (1914a), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Restall *et al.* (2006), Ridgely & Tudor (1989), Stattersfield & Capper (2000).



138. **Tricolored Brush-finch**

Atlapetes tricolor

French: Tohi tricolore **German**: Dreifarben-Buschammer **Spanish**: Atlapetes Tricolor
Other common names: Choco Brush-finch (*crassus*)

Taxonomy. *Buarremon tricolor* Taczanowski, 1875, Chilpes, Paltaypampa, Ninabamba, Pumarca and "Tembopata", Junín, Peru. Race *crassus* occasionally placed in *A. leucopis*, or treated as a separate species. Two subspecies currently recognized.

Subspecies and Distribution.
A. t. crassus Bangs, 1908 – W Andes of Colombia (Caldas, Valle and Nariño) and W Ecuador (Pichincha and El Oro).
A. t. tricolor (Taczanowski, 1875) – Andes of C Peru (La Libertad S to Junín and Cuzco).

Descriptive notes. 16–18 cm; 29·5–40 g. Nominate race has side of head black, contrasting wide yellowish crownstripe reaching to hindcrown and nape; upperparts dark olive to dark grey, rump and uppertail-coverts olive, tail blackish; upperwing dusky grey, feathers edged dark olive; throat and underparts bright yellow, washed olive on sides and flanks, vent and undertail-coverts; iris deep reddish-brown; bill black; legs greyish. Sexes alike. Juvenile has dull, dark rufous crown, dark brown back, and brown underparts sometimes streaked. Race *crassus* differs from nominate in having larger bill, darker back, tawny-gold headstripe, and more extensive olive on underparts. Voice. Song, given quite persistently, high-pitched and in two or three parts, tends to begin with 2 downslurred introductory notes, "tsuwee tsuwee, tsee-tsee, tsi-tsi-tsi", also described as a long series of accelerating notes terminating in dry trill; chatter-duet includes trills and descending nasal notes, and is relatively quick, high-pitched and sibilant, "pi tuee-chi tu-tu-tu zzz téw téw téw téw". Call a high "ti".

Habitat. Undergrowth in shrubby clearings and edge of humid forest; forest openings, and open mossy cloudforest. At 700–3050 m.

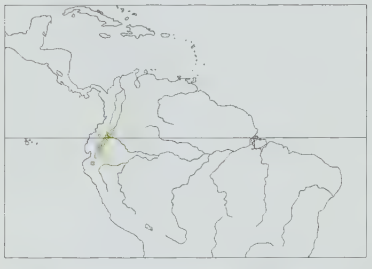
Food and Feeding. No details of diet. Forages at variable heights; can be distinctly more arboreal than many brush-finches, foraging 5–10 m from ground. Found alone and in pairs.

Breeding. Egg dates in Apr in Colombia (Valle), and fledglings in Jun–Jul in Cauca (Colombia) and NW Ecuador. One nest was a thick cup, placed near ground in rotten stump; contained 1 egg, white and densely spotted all over with dusky.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common; somewhat local. Has a reasonably wide global range, and no evidence of any widespread and/or significant population decline.

Bibliography. Armani (1985), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Hilty & Brown (1986), Paynter (1978), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).



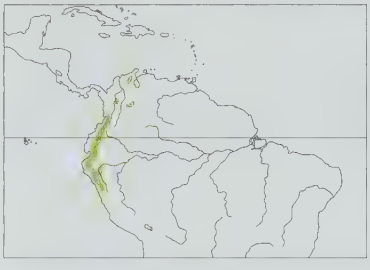
139. **White-rimmed Brush-finch**

Atlapetes leucopis

French: Tohi bridé **German**: Brillenbuschammer **Spanish**: Atlapetes de Anteojos

Taxonomy. *Buarremon leucopis* P. L. Sclater and Salvin, 1878, Yanayacu, Ecuador.

Race *crassus* of *A. tricolor* occasionally placed in present species. Monotypic.
Distribution. Colombian Andes from head of Magdalena Valley (S base of C Andes of SW Huila) and E slope of E Andes from W Caquetá S to W Putumayo and SE Nariño, and Ecuador on W slope (Imbabura) and E slope (at least Cordillera de Guacamayos, in Napo, also E Azuay and NW Morona-Santiago, also S Loja).



Descriptive notes. 18 cm. A very dark brush-finch with bold white "spectacles", bill rather thick at base with culmen evenly curved. Has dark rusty crown to hindcrown and upper nape, black face extending to malar region, contrasting bold white ring around eye and short white postocular stripe; upperparts, including wings and tail, blackish-grey, slight hint of olive on rump and uppertail-coverts; throat dark grey, underparts dark olive, slight darker scaling on breast (giving somewhat mottled appearance), flanks and undertail-coverts slightly darker olive than middle of belly and breast; iris dark brown; bill blackish; legs dull fleshy to dusky grey. Sexes alike. Immature has olive wash on crown, more noticeably barred appearance on throat and breast, and obscurely streaked belly. Voice. Song, heard in Mar, a slowly delivered series of 4–15 strident notes, either upslurred or downslurred whistles, varying from "swee twuu twuu twuu" to a longer "swee swee chewit chewit chewit tweew tweew chu chu"; also a rambling duet which includes many sweet whistles, trills and more complex notes. Contact call a high-pitched "zeee".
Habitat. Dense undergrowth of wet montane forest and forest edge; prefers a mix of forest with regenerating thickets and low montane woodland. At 2000–3100 m.
Food and Feeding. Little information on diet; observed to eat berries, particularly blue berries of Melastomataceae. Usually found on ground or low in understorey; foraging heights range up to 5 m above ground. Singly, in pairs and in groups of up to three individuals; may join mixed-species foraging flocks in some areas, but reported by some observers as not doing so.
Breeding. Recorded Oct–Dec in Colombia and Ecuador, and juveniles with adults seen in Dec in S Colombia (Nariño). Two nests described, one (under construction) a large ball of moss with large side entrance, 8 m above ground in fork of tree; the other was a bulky cup measuring 20 × 15 cm, made from twigs and grasses, placed c. 1·5 m above ground in a cavity 35 cm long, with entrance 25 × 18 cm, at base of a landslide. The cavity nest contained 1 egg, pale cream with greenish wash, and with chestnut-rufous blotches concentrated at wide end; egg being incubated. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Central Andes EBA and Southern Central Andes EBA. Rare to uncommon. Until recently was considered Near-threatened, but distribution appears to be more extensive and populations larger than had previously been realized. Abundant landslides occur in areas occupied by this brush-finch, and these may create the habitat mosaic it prefers.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Restall *et al.* (2006), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Salaman *et al.* (1998).

140. **Yellow-breasted Brush-finch**

Atlapetes latinuchus

French: Tohi à miroir **German**: Gelbbrust-Buschammer **Spanish**: Atlapetes Pechiamarillo
Other common names: Cloud-forest Brush-finch; Rufous-naped Brush-finch (*latinuchus*); Perija Brush-finch (*nigrifrons*); Yariguies Brush-finch (*yariguierum*)

Taxonomy. *Buarremon latinuchus* du Bus de Gisignies, 1855, Colombia and Peru.
Traditionally treated as conspecific with *A. rufinucha*, but molecular-genetic studies indicate that the two are not even each other's closest relatives. It has been suggested that these two species, together with *A. terborghi* and *A. melanolaemus*, and *A. schistaceus*, are related in a complex manner, with yellow coloration lost or gained in a leap-frog pattern, such that taxa which do not look alike visually may in fact be closely related to each other. Vocal data and molecular studies suggest that race *nigrifrons* may not belong with present species, is perhaps not even closely related to it, and possibly merits elevation to species rank; it should be noted that, when *Arremon torquatus* is placed in present genus, name *nigrifrons* becomes preoccupied and must then be replaced by name *phelpsi*. Proposed race *simplex* (described from Bogotá, and probably originating from E Andes of Colombia), appears indistinguishable from *spodionotus* and is synonymized with it. Nine subspecies currently recognized.
Subspecies and Distribution.
A. l. nigrifrons Phelps, Sr & Gilliard, 1940 – Perijá Mts, on N Colombia–W Venezuela border.
A. l. elaeoprorus (P. L. Sclater & Salvin, 1879) – NC Andes of Colombia in Antioquia.
A. l. yariguierum Donegan & Huertas, 2006 – Serranía de los Yariguíes (Santander), in Colombia.
A. l. caucae Chapman, 1927 – W Andes and W slope at S end of C Andes in Valle and Cauca, in Colombia.
A. l. spodionotus (P. L. Sclater & Salvin, 1879) – Andes in S Colombia (Nariño) and Ecuador (S to Chimborazo).
A. l. comptus (P. L. Sclater & Salvin, 1879) – SW Ecuador (from Cañar S to W Loja) and adjacent NW Peru (Piura).
A. l. latinuchus (du Bus de Gisignies, 1855) – SE Ecuador (from E Azuay and E Loja) S to N Peru (Amazonas).
A. l. chugurensis Chapman, 1927 – Pacific slope of Cajamarca, in NW Peru.
A. l. baroni (Salvin, 1895) – upper Marañón Valley in Cajamarca and La Libertad, in N Peru.

Descriptive notes. 17 cm; 16–31 g. Nominate race has forehead to nape medium rufous to orange-rufous, superciliary area and side of face black; upperparts dark slate-grey, upperwing and tail slightly darker, prominent white patch at base of primaries; tail blackish, edged olive; malar region and throat to undertail-coverts yellow, very narrow and indistinct dark malar stripe, side of breast and flanks with slight olive wash, greyer on rear flanks; iris deep reddish-brown; bill black; legs brownish to dusky grey. Sexes alike. Juvenile is dull olive above and on head, including crown, pale yellow below, breast and flanks washed olive and also indistinctly streaked. Race *nigrifrons* has black forehead, more olive wash on sides, flanks and thighs, no white patch at base of primaries; *elaeoprorus* is greenish-olive above, and has small pale supraloral spot and large white primary patch; *yariguierum* has blacker grey back than nominate, no white patch at base of primaries, malar stripe very small or lacking, more olive wash on sides and flanks; *caucae* has largest white primary patch, crown deep dark rufous, pale supraloral spot and olive-washed malar stripe; *spodionotus* is duller than nominate on upperparts and underparts, upperparts dark olive-brown, little or no white at base of primaries, malar stripe reduced to some indistinct olive-brown marks; *comptus* has yellow supraloral spot, black malar stripe, thighs washed olive; *baroni* has yellowish crownband becoming slightly more russet towards forehead, pale greenish upperparts, lacks dark malar stripe; *chugurensis* is much like last, but upperparts more greyish. Voice. Song fast and complicated, lasting c. 2–3 seconds, usually with three or four distinct parts and a characteristic opening trill, "t't't't't't'ut,weet-weet-weet-weet-tu-tu-few-few-few"; songs in N Peru simple, an introductory note and a trill, "swee tititititit" or "weeo chichichichi". Race *yariguierum* sings short series of high-pitched rising and falling whistles, "wiu-wiu, wiu-weeu-weeu, wee-weeu-weeu" or "wee-wiu-weeu-weeeu". Call a high-pitched "ztzzt".
Habitat. Inhabits bushy borders of forest, second growth, roadside thickets and overgrown pastures; moderately tolerant of disturbed habitats. Generally occurs at elevations of 1600–2700 m; up to 3700 m in Nariño (S Colombia).
Food and Feeding. No details of diet. May forage on ground, but often quite arboreal. Tends to forage in pairs or small groups, working the understorey; seldom joins mixed-species foraging flocks.
Breeding. Nests found in Aug and Oct in SE Ecuador (nominate race), and birds in breeding condition in Jan–Jun and juveniles observed in Aug in Perijá Mts (*nigrifrons*). Following details from SE Ecuador. One nest an untidy open cup of dead and dry leaves and leaf strips from various grasses, sedges (*Cyperus*), bromeliads and *Chusquea* bamboo, neat lining of finer pale fibres, mostly thin grass stems, external diameter 15–18 cm, height 12 cm, internal diameter 6 cm, depth 6 cm, well concealed c. 35 cm above ground among foliage of supporting sedges, horsetails (*Equisetum*) and various ferns, on which it rested (but only slightly covered from above); another nest was of very similar construction, 14 cm across and 9 cm tall, with inner cup 6 cm in diameter and 5·5 cm deep, placed 20 cm above ground and supported by numerous stems and blades of various grasses and sedges; both nests in heavily disturbed areas with much human traffic, one only 3 m from well-used trail through second growth still occasionally grazed (by horses). Clutch 2 eggs, white with red-brown and, to lesser extent, pale lavender flecks and spots, markings heaviest at larger end; at one nest, incubation apparently by one adult (presumed female), period 16 days, chicks fed by two adults, nestling period 15 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common. Because of its large global range, moderate to high level of abundance, and adaptability to disturbed habitats, this species is considered not to be at any immediate risk.

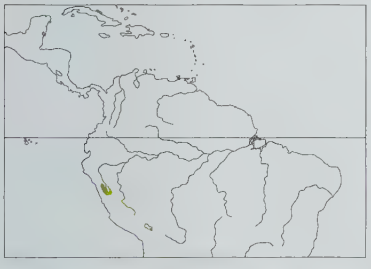
141. Antioquia Brush-finch

Atlapetes blancae

French: Tohi de Blanca **German**: Antioquiabuschammer **Spanish**: Atlapetes Antioqueño

Taxonomy. *Atlapetes blancae* Donegan, 2007, San Pedro de los Milagros, Antioquia, Colombia. Monotypic.
Distribution. San Pedro de los Milagros (in C Andes of Antioquia), in Colombia.



Descriptive notes. 17 cm. A largely pale greyish brush-finch, known only from museum specimens. Forehead to nape is rufous, with contrasting dark greyish face, blackish on lores and eyeline, very small pale grey supraloral spot; upperparts mid-grey, slightly darker wing and tail, very small white patch at base of primaries P4–P7; throat whitish-grey, narrow and short darker malar stripe; otherwise, pale greyish-white below, slightly darker on flanks; iris colour not known; bill and legs blackish. Sexes presumably similar. One of the specimens is a little browner and with smaller white primary patch, suggesting that it is younger in age. Voice. Unknown.
Habitat. No certain information; probably forest edge, 2400–2800 m.
Food and Feeding. No information.
Breeding. No information.
Movements. No information.
Status and Conservation. CRITICALLY ENDANGERED. Recently described on basis of museum specimens. Last record in 1971; currently known only from museum specimens. Possibly Extinct. Three specimens exist, all from type locality (San Pedro de los Milagros, in C Andes of Antioquia), two undated and the third dated 1971. Expeditions to type locality in 2007 and 2008 failed to find the species. All specimens were collected on a small plateau known as Llano de Ovejas, at 2400–2800 m. Likely that the species lived in forest, most of which in this region has been destroyed for cattle-ranching and commercial flower-growing. Further investigation of this species' potential distribution is required, followed by intensive targeted searches.
Bibliography. Anon. (2010c), Donegan (2007), Donegan *et al.* (2009).

142. Rufous-eared Brush-finch

Atlapetes rufigenis

French: Tohi rougeaud **German**: Rotohr-Buschammer **Spanish**: Atlapetes Orejirrufo

Taxonomy. *Buarremon rufigenis* Salvin, 1895, Huamachuca, 10,400 feet [c. 3170 m], La Libertad, and Cajabamba, 11,000 feet [c. 3350 m], Cajamarca, Peru.
Until recently usually treated as conspecific with *A. forbesi*. Monotypic.
Distribution. Upper Marañón Valley from Cajamarca S to Ancash and Huánuco, in Andes of W Peru.

Descriptive notes. 17·5–19 cm. A relatively large brush-finch with large-headed look and long, wide tail. Head is almost entirely rufous, including side of neck and nape, darker greyish immediately in front and below eye, white supraloral area invading lores, long white submoustachial area, narrower dusky grey malar stripe; upperparts grey with olive wash, upperwing and tail slightly darker; throat gleaming white, breast and flanks greyish, belly and undertail-coverts whitish; iris dark red; bill blackish; legs brownish. Sexes alike. Juvenile has grey-brown crown, and all grey areas of plumage washed brown, lores, supraloral area and throat as on adult, breast and sides dark brown, belly whitish. Voice. Song described as a variation on 4 different notes, repeated every 4–6 seconds, each phrase 1–2 seconds long, "chit let teeuit, chit teeuit, chi tui, chi tui teeuit..."; chatter-duet a pleasant set of liquid sounding trills, the whole lasting 3–5 seconds. Call "tzi".
Habitat. Dense undergrowth and shrubbery in patches of woodland, including *Polylepis* forest; also dense shrubby dry slopes, and undergrowth in both dry and humid *Podocarpus* or alder (*Alnus*) woodlands, as well as dense *Polylepis–Gynoxys* woodland, and tree-line shrubbery. At 2750–4100 m.
Food and Feeding. No information on diet. Tends to forage 0·5–1·5 m up, rarely to 5 m above ground; usually in undergrowth. Also forages while on thick, moss-covered branches in humid forest.
Breeding. Juveniles in Jun in La Libertad and in Feb–Mar in Ancash. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Peruvian high Andes EBA. Uncommon to locally fairly common. Has a relatively small, fragmented range, and is probably declining following habitat loss through deforestation. Main threats are reduction of mixed *Polylepis* woodland caused by cutting for firewood, and ensuing lack of regeneration because of burning and intensive grazing; also, changes in farming (from camelid stock to sheep and cattle), soil erosion and degradation caused by agricultural intensification, road-building, and inadequate planning of afforestation projects, especially the planting of eucalypts (*Eucalyptus*) and other exotic species. Occurs in Huascarán National Park (Ancash), where until recently habitat degradation was continuing, although a conservation scheme for *Polylepis* is now in place.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

143. Apurimac Brush-finch

Atlapetes forbesi

French: Tohi de Forbes **German**: Forbesbuschammer **Spanish**: Atlapetes de Apurímac
Other common names: Black-spectacled Brush-finch(!)

Taxonomy. *Atlapetes forbesi* Morrison, 1947, Pomayaco, 9100 feet [c. 2775 m], Pampas River valley, 80 miles [c. 130 km] south-east of Ayacucho, Apurímac, Peru.
Until recently usually treated as conspecific with *A. rufigenis*. Monotypic.
Distribution. Andes of S Peru (E Apurímac and adjacent Cuzco).

Descriptive notes. 18 cm. A dark-backed whitish bellied brush-finch with long bill only moderately deep at base. Has mostly rufous head, including nape and side of neck, but with black forehead, whitish supraloral area contrasting with black area on lores and around eye, long white submoustachial area, blackish malar stripe; upperparts grey, upperwing and tail slightly more blackish; white edge at bend of folded wing (created by protruding wing-lining); throat white, largely grey below, with whitish down central area of abdomen; iris brown; bill blackish; legs dark greyish. Sexes alike. Juvenile is brownish above, including crown and face, eye surrounded by black, throat whitish, breast and flanks brown and mottled in appearance, belly white; immature has underparts like adult, but acquires tawny-rufous on head slowly, first on nape and hindcrown. Voice. Song "tchip tséév! Tchi pi-pi", or sometimes only the "tchip tséév!" given and then a pause before this repeated; chatter-duet a series of nasal thin whistles and slow trills. Call a high "pi".
Habitat. Montane scrub and *Polylepis* forest, at 2700–4600 m.
Food and Feeding. Little known. Forages on or close to ground.
Breeding. Birds in breeding condition in Mar and fledglings seen in May in Apurímac. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common. Despite its small global range, this species is thought not to be under any immediate pressure, and there are no problems evident concerning its habitat.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

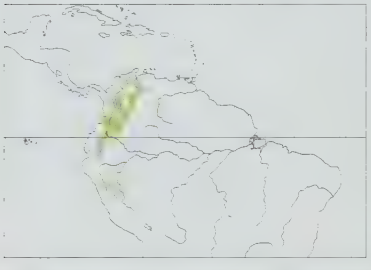
144. Black-spectacled Brush-finch

Atlapetes melanopsis

French: Tohi à face noire **German**: Schwarzbrillen-Buschammer **Spanish**: Atlapetes de Anteojos

Taxonomy. *Atlapetes melanopsis* Valqui and Fjeldså, 2002, 4 km south-east of Huachocollpa, Tayacaja Province, Huancavelica, Peru.
Originally described under name *A. melanops*, but this name is preoccupied. Monotypic.
Distribution. S Junín and N Huancavelica (just N & S of R Mantaro), in SC Peru.

Descriptive notes. 19 cm. A dark-backed brush-finch with long bill only moderately deep at base. Has largely rufous head, including nape and side of neck, with lower forehead black, supraloral area whitish, contrasting with large black area around eye, long white submoustachial area bordered by narrow blackish malar stripe; upperparts grey, rump washed olive, upperwing and tail slightly more blackish; white edge at bend of folded wing (created by protruding wing-lining); throat white, largely grey below, with paler area on central flanks, and whitish down central part of abdomen; iris brownish-red; bill blackish; legs dark greyish. Sexes alike. Juvenile apparently undescribed. Voice. Song begins with accented pair of introductory notes and then chipping notes, these running together into a trill, "Tweew-sweet! chew-chew-twip-twip-twippipipipi"; chatter-duet similar, but longer and more complex, involving many more trills, chatters and nasal notes. Calls include liquid "twiit", repeated when bird agitated.
Habitat. Montane scrub and forest edge in seasonally humid regions (absent from humid E-slope areas); found in dry bushy areas (in a zone with fairly high seasonal rainfall) and adjacent ecotones between these and humid slopes. At 2500–3600 m.
Food and Feeding. Appears to feed on seeds and insects. Forages from ground level to 3 m above ground. Searches while moving along branches; sometimes hangs from an inflorescence, perhaps to eat seeds. Singly and in groups of up to three individuals.
Breeding. No information.
Movements. No information.
Status and Conservation. ENDANGERED. Locally uncommon. Total range, as currently known, is very small, and threat to its remaining habitat suggests a continuing reduction in range and numbers. Estimated total population in range 2500–9999 mature individuals. Since its initial discovery, in 1996, recorded at only few sites. Main threat is the burning of early regenerating natural vegetation in order to maintain and increase available pasture, a practice that is widespread (except in steep, rocky areas and ravines) in this species' range.
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), García-Moreno & Fjeldså (1999), Schulenberg *et al.* (2007), Stattersfield & Capper (2000), Valqui & Fjeldså (1999, 2002).



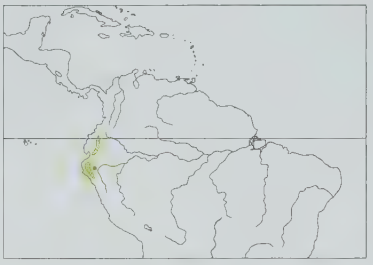
On following pages: 145. Slaty Brush-finch (*Atlapetes schistaceus*); 146. White-winged Brush-finch (*Atlapetes leucopterus*); 147. White-headed Brush-finch (*Atlapetes albiceps*); 148. Pale-headed Brush-finch (*Atlapetes pallidiceps*); 149. Bay-crowned Brush-finch (*Atlapetes seebohmi*); 150. Rusty-bellied Brush-finch (*Atlapetes nationi*); 151. Cuzco Brush-finch (*Atlapetes canigenis*); 152. Vilcabamba Brush-finch (*Atlapetes terborghi*); 153. Black-faced Brush-finch (*Atlapetes melanolaemus*); 154. Bolivian Brush-finch (*Atlapetes rufinucha*); 155. Fulvous-headed Brush-finch (*Atlapetes fulviceps*); 156. Yellow-striped Brush-finch (*Atlapetes citrinellus*).

145. Slaty Brush-finch

Atlapetes schistaceus

French: Tohi ardoisé **German**: Graubrust-Buschammer **Spanish**: Atlapetes Pizarroso
Other common names: Taczanowski's Brush-finch (*taczanowskii*)

Taxonomy. *Tanagra* (*Arremon*) *schistaceus* Boissonneau, 1840, Santa Fe de Bogotá, Colombia.
Until recently, generally treated as conspecific with *A. canigenis*. Sometimes thought to form a superspecies with *A. seebohmi* and *A. nationi*, and often considered conspecific with former. Has been suggested that this species and *A. terborghi*, *A. melanolaemus* and *A. rufinucha* are related in a complex manner, with yellow coloration lost or gained in a leap-frog pattern, such that taxa which do not look alike may in fact be closely related to each other. Race *taczanowskii* possibly represents a separate species; further study needed. Five subspecies recognized.
Subspecies and Distribution.
A. s. fumidus Wetmore & Phelps, Jr, 1953 – Sierra de Perijá, on N Colombia–W Venezuela border.
A. s. castaneifrons (P. L. Sclater & Salvin, 1875) – Andes of Venezuela (Trujillo, Mérida and C & E Táchira).
A. s. tamae Cory, 1913 – W Venezuela (SW Táchira) and adjacent Colombia (Norte de Santander).
A. s. schistaceus (Boissonneau, 1840) – W & C Colombian Andes (S from Antioquia and Norte de Santander) and N & C Ecuador.
A. s. taczanowskii (P. L. Sclater & Salvin, 1875) – Andes of C Peru (Huánuco S to Junin).



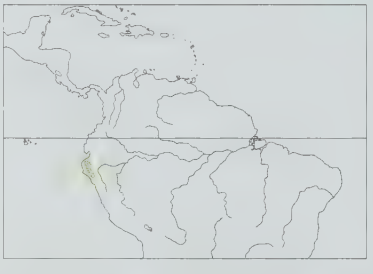
Descriptive notes. 18 cm; 22·6–43·9 g. A largely greyish brush-finch. Nominate race has crown to nape rusty, face down to lower edge of ear-coverts and back to side of neck black, usually a small whitish spot on lores, long white moustachial stripe bordered by narrow black malar stripe; upperparts dark grey, contrasting with blackish upperwing and tail, primaries with white bases (forming a noticeable white patch on folded wing), white edge at bend of folded wing (created by white marginal coverts); throat whitish with small dark spots, breast, flanks and undertail-coverts mid-grey, central belly whitish; iris dark reddish-brown; bill blackish; legs brown-grey. Sexes alike. Juvenile similar to adult, but rusty crown veiled with black, breast and flanks streaked blackish and white wing patch smaller. Race *taczanowskii* is similar to nominate, but top of head much paler, looking russet or pale orange, darker on crown, and paler on nape, lacks white primary patch, juvenile olive above and pale greyish below, with olive flanks and breast and noticeably streaked; *castaneifrons* is similar to nominate, but top of head paler (though not so pale as previous), upperparts darker, nearly blackish, and contrasting little, if at all, with blackish face and nape, lacks white primary patch, juvenile like adult but streaked on breast; *fumidus* is like last, but paler above and darker below, central belly only slightly paler than rest of underparts; *tamae* is dark, like *castaneifrons*, and with similarly coloured crown patch, but larger and with darker underparts, belly only slightly paler grey than breast, also lacks white primary patch. Voice. Song an energetic series of high-pitched trills and squeaks, ending in distinctive repeated "chewy-chewy-chewy" or "t'chew t'chew t'chew"; song of race *taczanowskii* variable, a pleasant series of rich introductory notes and then a trill or series of notes, "chew-chew-chew zéééééé"; chatter-duet includes mellow "du-du-dew-dew" mixed with trills and chatters. Contact call a fine "tzit-tzit-tzit".
Habitat. Shrubby forest borders and undergrowth of humid woodland, reaching to tree-line. Found in cloudforest, moist montane second-growth woodlands, *páramo* with frailejón (*Espeletia*), elfin forest, and in Venezuela also humid *Polylepis* forest; avoids continuous forest. At 2500–3800 m, sometimes down to 1800 m.
Food and Feeding. Diet includes insects and fruit. More arboreal, less terrestrial, than other brush-finches. Tends to forage from ground level to 5 m up; usually in undergrowth. Can be restless when foraging, and often climbs vines in search of food. Usually alone or in pairs; commonly joins mixed-species foraging flocks, often with various other species of brush-finch.
Breeding. In Colombia, fledglings observed in Apr–Aug in Cauca and Apr in Cundinamarca and birds in breeding condition in Apr–Sept in N and in Nov in Cundinamarca; in Venezuela, fledglings observed in Aug and birds in breeding condition in Nov. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Common in Venezuela and Colombia; uncommon in Ecuador; fairly common in Peru. No known threats. Because of its large range, generally good levels of abundance and lack of any clear and significant population declines, this species is considered not to be at any immediate risk.
Bibliography. Armani (1985), Donegan (2007), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Hilty (2003), Hilty & Brown (1986), Paynter (1972), Remsen & Graves (1995a), Restall *et al.* (2006), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stiles *et al.* (2000).

146. White-winged Brush-finch

Atlapetes leucopterus

French: Tohi leucoptère **German**: Spiegelbuschammer **Spanish**: Atlapetes Aliblanco
Other common names: White-cheeked Brush-finch (*dresseri*); Paynter's Brush-finch (*paynteri*)

Taxonomy. *Arremon leucopterus* Jardine, 1856, eastern cordillera of Ecuador ["eastern" probably a *lapsus* for "western", although the species may occasionally occur on E slope].
Has been suggested that race *paynteri* be elevated to species rank; further study needed. Three subspecies recognized.
Subspecies and Distribution.
A. l. leucopterus (Jardine, 1856) – W slope in Ecuador (S to Chumbo Valley).
A. l. dresseri (Taczanowski, 1883) – SW Ecuador (El Oro and Loja) and NW Peru (Tumbes S to Cajamarca).
A. l. paynteri Fitzpatrick, 1980 – extreme NE Piura and N Cajamarca (Cordillera del Condor), in NW Peru.
Descriptive notes. 15·5–16·5 cm; 19–26·5 g. The smallest brush-finch, dark-backed, whitish-bellied, with large white patch at base of primaries, long bill only moderately deep at base. Nominate race has top of head russet, darker on forecrown than on hindcrown and nape, blackish superciliary area and face extending to side of neck, contrasting whitish-buff supraloral area; upperparts dark grey, upperwing and tail similarly dark, white bases of primaries (creating large white primary patch), white edge at bend of folded wing (created by white marginal coverts); largely whitish below, some blackish speckling at edge of throat, buffy and greyish wash on sides and flanks; iris dark brownish-red; bill blackish; legs blackish-brown. Sexes alike. Juvenile has buffy crownstripe, upperparts olive, breast and flanks streaked. Race *dresseri* is smaller-billed than nominate, plumage variable, has black forehead of variable extent, and (except in N of range) some white on head varying from an area around eye to a large part of head; *paynteri* has white hindcrown and nape, but side of head black, is also more greyish on body, lacking slight olive wash of previous. Voice. Race *dresseri* song a two-part series of high-pitched thin notes, lacking many warbled phrases; call a high descending "tseeu". Song of *paynteri* a musical and pleasant "chew-chew tee-tee" or "chee-chee tewr tewr", call a high "ti".



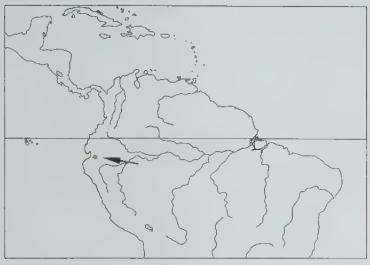
Habitat. Dry to fairly humid brushy areas and low woodlands. May occupy very dry shrubby hillsides with scattered *Bombax* trees in NW Ecuador; also gardens, villages, and shrubbery at edge of humid forest and even edge of cloudforest. Race *paynteri* prefers more humid forest undergrowth than other races. At 600–2900 m.
Food and Feeding. One stomach contained mostly ants (Formicidae), as well as grit. Forages on and near ground. Typically, observed to scratch in leaf litter on ground. In pairs and in small groups, possibly family parties; sometimes in flocks of as many as 20 or 30 individuals, which may associate with other brush-finches.
Breeding. Juveniles in Jun in S Ecuador (Loja). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common in Ecuador; fairly common in Peru, where race *paynteri* rare to locally fairly common. This species is reasonably widespread and relatively common, with no signs of any substantial population declines. If *paynteri* is accorded full species rank, it may require a full assessment of its status, as it has a very small range.
Bibliography. Armani (1985), Donegan (2007), Fitzpatrick (1980), Fjeldså & Krabbe (1990), McCarthy (2006), Paynter (1972), Restall *et al.* (2006), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

147. White-headed Brush-finch

Atlapetes albiceps

French: Tohi à tête blanche **German**: Weißkopf-Buschammer **Spanish**: Atlapetes Cabeciblanco

Taxonomy. *Buarremon albiceps* Taczanowski, 1884, Paucal, Cajamarca, Peru.
Monotypic.
Distribution. W slope of Andes in extreme S Ecuador (S Loja) and adjacent NW Peru (S to Lambeyeque).



Descriptive notes. 16 cm. A typically shaped brush-finch with moderately sized bill showing relatively straight culmen. Has most of head white, with strongly contrasting blackish cap and nape, and sometimes some dark speckling on lores; dark orbital skin gives impression of large, dark eye; upperparts slate-grey, slightly more blackish on wing and tail, white bases of primaries (creating noticeable large white wing patch); very narrow blackish malar stripe, throat white, becoming greyish on breast and flanks, but with whitish belly and vent (rear underparts sometimes washed buffy); iris dark; bill black; legs greyish. Sexes alike. Juvenile undescribed. Voice. Song a series of squeaky whistled notes, "Pee-ti-ti séw-tew'tew'tew' see-see"; chatter-duet a liquid and descending chatter, with interspersed high-pitched twitters and screeches. Calls include high "ti" and "tseeip", as well as high-pitched rising and falling "tseeéée".
Habitat. Found in undergrowth of low dry scrubby woodland, particularly along streams in dry montane regions; 400–1400 m.
Food and Feeding. Stomach contents included small seeds, larger seeds (crushed), and insects. Forages on ground, as well as in low shrubbery. Sometimes forms relatively large flocks, and mixes with other brush-finches, such as *A. leucopterus*.
Breeding. Specimen from S Ecuador in breeding condition (and plumage quite worn) in late May; season estimated as Jan–Feb. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian region EBA. Locally common or fairly common. No evidence of any population declines, and considered not to be at any immediate risk.
Bibliography. Paynter (1972), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

148. Pale-headed Brush-finch

Atlapetes pallidiceps

French: Tohi grisonnant **German**: Blasskopf-Buschammer **Spanish**: Atlapetes Cabecipálido

Taxonomy. *Buarremon pallidiceps* Sharpe, 1900, Guishapa, Oña, Azuay, Ecuador.
Monotypic.
Distribution. S Azuay (upper Jubones Valley), in SW Ecuador.
Descriptive notes. 16 cm. A largely whitish brush-finch with darker back, dark wings and tail, and long, relatively pointed bill. Head is mostly whitish, with brownish forehead, lores and area around eye (variable whitish eyering), and grey-brown postocular stripe which becomes wider on back of head and bands sharply downwards to wrap around rear of ear-coverts; narrow ill-defined brownish malar stripe; nape to lower back greyish-brown, rump whitish; tail blackish-brown; upperwing blackish, white at base of primaries (noticeable white patch on folded wing); white below, washed pale brownish on side of breast, flanks and vent; iris dark brown; bill black; legs grey to blackish.

Sexes alike. Juvenile has brown crown, pale supraloral spot, slate-grey ear-coverts and blackish malar stripe, slaty colour of head continuing to chin, below which a buffy collar, and rest of underparts buffy grey, darker on breast and flanks, bill yellowish-horn with blackish culmen; immature darker brown ear-coverts and darker brownish wash on underparts. VOICE. Song a deshtcending short trilling chatter, "ch-chwewewewe". Call a high-pitched "teep"; sometimes partners give rapid series of calls in a flurry when in direct view of each other.

Habitat. Low arid scrubby woodland of composite and verbenaceous species on dry slopes, with acacias (*Acacia*) and lauraceous trees in damper parts, interspersed with old or newer grassland; retreats into shady thickets in ravines during heat of day. At 1650–2100 m.

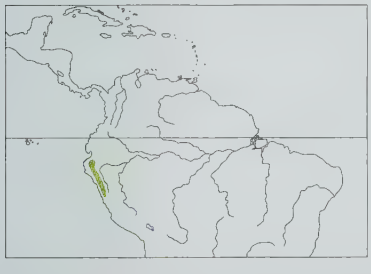
Food and Feeding. Insects, also fruits and berries (*Rubus*, *Solanum*, *Morus*), as well as seeds such as those of *Polygonum*. Stomach contents have included small seeds, large seeds and insect material. Relatively arboreal for a brush-finch; forages both on the ground and within 4 m of ground. Furtive. Will sally for insects. Sometimes join mixed-species foraging flocks, and is attracted to army-ant (Formicidae) swarms.

Breeding. Breeds in Feb–Jun, in rainy season; some make up to two renesting attempts after failures early in season. Nest built by female, a bulky cup made from dry grass, twigs, stems and bamboo stems, a small amount of moss and lichen also present, lining of fine grass, bamboo leaves and leaf fibres, placed 0·84–3·02 m (average 1·84 m) above ground and often attached to thin twigs of shrub or vines, or placed in fork of branch or along main stem of upright bush. Clutch 2–3 eggs, buffy white, pale bluish or pale pinkish with small or large brownish or purplish spots and blotches throughout; incubation by female; no information on duration of incubation and nestling periods. Nests commonly parasitized by Shiny Cowbird (*Molothrus bonariensis*). In 2002, reproductive output only 0·74 young per breeding pair; at two sites, rates of brood parasitism were 15% and 61%, and predation rates also high (only slightly lower than parasitism rates).

Movements. Sedentary.

Status and Conservation. ENDANGERED. Restricted-range species: present in Tumbesian Region EBA. Rare. Formerly listed as Critically Endangered, but, in view of its increasing numbers, this species has recently been reassessed. Known only from one small area in Ecuador, in upper R Jubones Valley (S Azuay), particularly in vicinity of Girón and Oña. Global population, based on 2009 census data, thought to be c. 220 adults. Within its range, its habitat has historically been decreasing, although concerted conservation action in recent past has allowed its population to increase. Yunguilla Reserve was purchased especially for protection of this species. Particular problems are the grazing activity of goats and cattle, which seems to decrease quality of habitat for this brush-finch, fire, and also, especially, Shiny Cowbird parasitism (in 2002, 61% of pairs in Yunguilla Reserve were parasitized). Seven years after initiation of a programme of trapping and removal of cowbirds, the numbers of present species had increased markedly, from fewer than 40 pairs to more than 100 pairs, this small recovery aided also by habitat restoration. Yunguilla Reserve covers 150–200 ha and holds 98% of known brush-finch territories. Plans for further land purchases, mainly immediately N of the reserve, should, if they succeed, enable a second reserve to be set up; this would allow for translocation of a suitable number of birds once present population has reached 200 pairs.

Bibliography. Agreda *et al.* (1999), Anon. (2010c), Butchart & Stattersfield (2004), Hirschfeld (2007), Krabbe (2004), Krabbe *et al.* (2011), Oppel, Schaefer & Schmidt (2003), Oppel, Schaefer, Schmidt & Schroeder (2004a, 2004b, 2004c), Paynter (1972), Ridgely & Tudor (1989), Stattersfield & Capper (2000).



149. Bay-crowned Brush-finch

Atlapetes seebohmi

French: Tohi de Seebohm **German**: Rotscheitel-Buschammer **Spanish**: Atlapetes de Seebohm
Other common names: Celica Brush-finch (*celicae*); Simons's Brush-finch (*simonsi*)

Taxonomy. *Carenochrous seebohmi* Taczanowski, 1883, Cajacay, Cajatambo, Ancash, Peru.
Sometimes thought to form a superspecies with *A. schistaceus* and *A. nationi*, and often considered conspecific with one or the other. Race *celicae*, known from a single specimen, may be an aberrant individual of *simonsi*. Three subspecies recognized.

Subspecies and Distribution.
A. s. celicae Chapman, 1925 – W Loja (region of Celica), in SW Ecuador.
A. s. simonsi (Sharpe, 1900) – C & E Loja, in S Ecuador.
A. s. seebohmi (Taczanowski, 1883) – Pacific slope of Andes in NW Peru (S to Ancash).

Descriptive notes. 16–17 cm. A large-bodied brush-finch with deep-based, long and strong-looking bill. Nominate race has deep rufous crown to nape, contrasting with a entirely black face (extending to forehead); throat and moustachial region white, chin black and continuing as short black malar stripe (this stripe ends half-way down side of throat); upperparts olive-grey, upperwing and tail slightly darker, white edge at bend of folded wing (marginal coverts); light grey breastband, palest at centre, the grey extending down flanks and becoming olive-grey on rear flanks; lower breast and belly whitish, becoming buffy on crissum; iris dark red-brown; bill black; legs greyish. Sexes alike. Juvenile is browner above than adult, throat and belly buffy, breast and flanks indistinctly streaked. Race *simonsi* has rufous forehead, is darker grey than nominate, and has small whitish supraloral spot; *celicae* is like previous, but smaller, with small amount of black on forehead, throat washed buffy. VOICE. Song a quickly delivered "chew-chew wit-chew" or shorter "chew-chew'trrrrr". Call a high-pitched "tsiip"; also a sharp "piit" or "put", repeated quickly when alarmed.

Habitat. Undergrowth in low scrubby montane woodland, also shrubby hillsides with low vegetation (reaching only to chest height), in rather dry regions; 1150–2800 m.

Food and Feeding. Stomach contents have included large insects, as well as seeds and fruit. Forages close to ground; also drops to ground and scratches in leaf litter. Generally in pairs or small groups.

Breeding. Known to breed during rainy season, approximately Mar–May. No further information available.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon to locally fairly common. Because of its relatively extensive range, local abundance and lack of any specific threats to populations, this species is considered not to be at any immediate risk.

Bibliography. Armani (1985), Bond (1951a), Paynter (1972), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

150. Rusty-bellied Brush-finch

Atlapetes nationi

French: Tohi à ventre roux **German**: Rostbauch-Buschammer **Spanish**: Atlapetes Ventrirrufo

Taxonomy. *Buarremon nationi* P. L. Sclater, 1881, western Andes above Lima, 10,000–14,000 feet [c. 3050–4270 m], Peru.
Sometimes thought to form a superspecies with *A. schistaceus* and *A. seebohmi*, and often considered conspecific with one or the other. Two subspecies recognized.

Subspecies and Distribution.
A. n. nationi (P. L. Sclater, 1881) – Andes of W Peru (Lima).
A. n. brunneiceps (Berlepsch & Stolzmann, 1906) – Andes of SW Peru (Ica and Ayacucho S to Arequipa).

Descriptive notes. 17 cm; 40·5–43·4 g. A large-bodied brush-finch with deep-based, long and strong-looking bill. Nominate race has forehead and face entirely black, with dark olive-brown crown (in most field conditions looks blackish-capped), some individuals having a few random white feathers on crown; throat and moustachial region white, chin black and continuing as short black malar stripe (this stripe ends half-way down throat side); upperparts lead-grey, upperwing and tail slightly darker, white edge at bend of folded wing (marginal coverts); throat and foreneck white, broad grey breastband extending broadly down flanks, isolating cinnamon-buff belly to crissum; iris dark red-brown; bill blackish; legs grey to dusky brown. Sexes alike. Juvenile is similar to adult, but brown-washed above, throat to central belly buff, and brownish breast and flanks streaked with buff. Race *brunneiceps* is paler than nominate, paler greyish with slight olive tone above, white speckling on supercilium, side of face and sometimes crown, much paler below, breastband very pale and indistinct, also cinnamon of lower underparts paler, more tawny or dark buff, and extending higher up towards breastband, over much of flanks and even as a wash on throat (making throat look buffy). VOICE. Song apparently unrecorded. Calls include rich, hard "tchip", also high-pitched "ti"; another call, perhaps a begging call, is a repeated nasal "zzppp".

Habitat. Patches of woodland and shrubby Andean slopes, in relatively dry environments; 2000–4000 m.

Food and Feeding. Forages in pairs and in small groups, at or near ground. No other information available.

Breeding. Juveniles in Lima in Jun. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian High Andes EBA. Uncommon to fairly common; very local. Has a sufficiently broad range, and no evidence of any marked decline in its numbers or threats to the population.

Bibliography. Armani (1985), Bond (1951a), Fjeldså & Krabbe (1990), McCarthy (2006), Paynter (1972), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

151. Cuzco Brush-finch

Atlapetes canigenis

French: Tohi à joues grises **German**: Schieferbuschammer **Spanish**: Atlapetes de Cuzco
Other common names: Grey/Sooty Brush-finch

Taxonomy. *Atlapetes canigenis* Chapman, 1919, Torontoy, 9500 feet [c. 2900 m], Urubamba Canyon, Cuzco, Peru.
Until recently, generally treated as conspecific with *A. schistaceus*. Monotypic.

Distribution. Andes of Cuzco, in S Peru.

Descriptive notes. 18 cm. A dark brush-finch with little contrast in plumage. Has forehead to crown and entire nape tawny-orange, ear-coverts grey in centre, otherwise side of head and side of neck blackish; upperparts grey, rump and uppertail-coverts sometimes with slightly paler or warmer tone; upperwing and tail darker, slate-grey; below, medium-grey, throat and belly slightly paler grey, weakly defined and narrow blackish moustachial stripe and malar stripe; iris dark brown; bill and legs blackish. Sexes alike. Juvenile undescribed. VOICE. Chatter-duet includes cascading trill that descends in frequency, as well as nasal notes and buzzy sounds. Call a high "tip".

Habitat. Humid montane forest edge and scrub; 2500–3500 m.

Food and Feeding. Forages on or near ground. No other information.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common. Although restricted in range, this species is common where it lives, and there is no imminent threat to its habitat; considered currently not to be at any risk.

Bibliography. García-Moreno & Fjeldså (1999), Paynter (1972), Remsen & Graves (1995a), Schulenberg *et al.* (2007).

152. Vilcabamba Brush-finch

Atlapetes terborghi

French: Tohi de Terborgh **German**: Vilcabambabuschammer **Spanish**: Atlapetes de Vilcabamba

Taxonomy. *Atlapetes terborghi* Remsen, 1993, Cordillera Vilcabamba, Cuzco, Peru.
Often considered a race of *A. latinuchus*, and both were originally considered part of a wider complex that included also *A. melanolaemus* and *A. rufinucha*, although recent studies suggest that various components of this group may not be each other's closest relatives. Present species likely most closely related to *A. melanolaemus*. Monotypic.
Distribution. Cordillera Vilcabamba (W Cuzco), in S Peru.

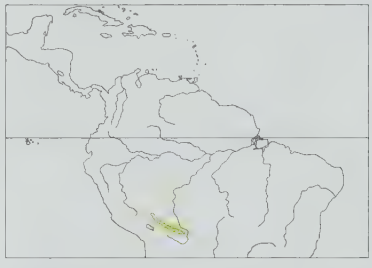
Descriptive notes. 17 cm. A dark brush-finch with yellow underparts. Has rufous area from cap to nape, darkest on forehead; face, including lores, superciliary area and ear-coverts, blackish; upperparts blackish, olive wash from back to uppertail-coverts, more olive in rump area; upperwing and tail blackish, tail edged olive; below, yellow from throat to undertail-coverts, breast and flanks tinged greenish; iris dark brown; bill black; legs blackish. Sexes alike. Juvenile undescribed. Voice. No information.
Habitat. Humid montane cloudforest and elfin forest; 2520–3520 m.
Food and Feeding. No information.
Breeding. All of a series of specimens were in breeding condition in Jul, the dry season in this section of Andes. No other information.
Movements. No information.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. A poorly known species; appears to be uncommon. Has very small global range. Numbers apparently stable, and currently there are no large-scale threats to this species' habitat; few, if any human habitations within its range. Although populations apparently secure at present, this brush-finch could rapidly become threatened if human pressures within its range increase.
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), García-Moreno & Fjeldså (1999), Remsen (1993), Remsen & Graves (1995a), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

153. Black-faced Brush-finch

Atlapetes melanolaemus

French: Tohi mélanien **German**: Schwarzgesicht-Buschammer **Spanish**: Atlapetes Carinegro
Other common names: Dark-faced Brush-finch

Taxonomy. *Buarremon melanolaemus* P. L. Sclater and Salvin, 1879, Cchachupata, Cuzco, Peru.
Often considered a race of *A. latinuchus*, and both were originally considered part of a wider complex that included also *A. terborghi* and *A. rufinucha*, although recent studies suggest that various components of this group may not be each other's closest relatives. Present species likely closest to *A. terborghi*. One specimen of nominate race of *A. rufinucha* from La Paz (Bolivia) exhibits dark scalloping on breast, approaching present species; unclear if this is a variation in former species or due to gene flow between the two. Monotypic.
Distribution. SE Peru (E Cuzco and adjacent Puno) and adjacent W Bolivia (extreme N La Paz).



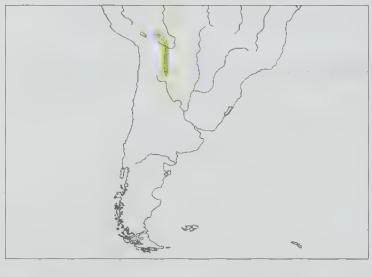
Descriptive notes. 17 cm; 27·5–30·3 g. A dark brush-finch with yellow underparts and dark scaling about breast. Has bright rufous forehead to crown and nape; face, including lores, superciliary area and ear-coverts, blackish, dusky coloration extending to malar region and throat; upperparts blackish, rump with slight olive wash; tail blackish, edged olive; upperwing wholly blackish; breast to undertail-coverts dull yellow, breast with dusky scaling and flanks washed dusky olive (underparts look very dull-coloured, not bright yellow); iris dark reddish; bill black; legs blackish. Sexes alike. Juvenile undescribed. Voice. Song short and explosive, "Cheoo Ch-Wha-Chee", as well as a pleasant "Chew-wi Tee-tee" or sometimes ending with trill, "Cheoo chup-tititititititi"; chatter-duet includes many nasal trills, stutters and chatters. Call a high-pitched "tiip".
Habitat. Humid montane forest and shrubby slopes; 1400–3200 m.
Food and Feeding. Forages on or near ground. No other information.
Breeding. Birds in breeding condition in Dec. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common to fairly common. Has a small, but not tiny, global range, within which it is not uncommon. In addition, no imminent threat to stability of populations, and therefore considered not at any immediate risk.
Bibliography. Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Paynter (1978), Remsen (1993), Remsen & Graves (1995a), Schulenberg *et al.* (2007).

154. Bolivian Brush-finch

Atlapetes rufinucha

French: Tohi à nuque rousse **German**: Rotnacken-Buschammer **Spanish**: Atlapetes Nuquirrufo
Other common names: Rufous-naped Brush-finch

Taxonomy. *Embernagra rufi-nucha* d'Orbigny and Lafresnaye, 1837, Yungas, La Paz, Bolivia.
Often considered conspecific with *A. latinuchus*, and both were originally considered part of a wider complex that included also *A. terborghi* and *A. melanolaemus*, although recent studies suggest that various components of this group may not be each other's closest relatives. It has been suggested that all of these the species, and also *A. schistaceus*, are related in a complex manner, with yellow coloration lost or gained in a leap-frog pattern, such that taxa which do not look alike may in fact be closely related to each other. One specimen of present species from La Paz exhibits dark scalloping on breast, approaching *A. melanolaemus*; unclear if this is a variation in nominate race or due to gene flow between the two species. Name "*Buarremon melanops*" refers to specimens apparently assignable to nominate form of present species. Two subspecies recognized.
Subspecies and Distribution.
A. r. rufinucha (d'Orbigny & Lafresnaye, 1837) – subtropical zone of Andes of La Paz and Cochabamba, in WC Bolivia.
A. r. carrikeri J. Bond & Meyer de Schauensee, 1939 – Andes of Santa Cruz, in C Bolivia.



Descriptive notes. 17 cm; 20·9–22·2 g. Nominate race has blackish forehead, striking rufous crown to nape; face blackish, accented by bright yellow supraloral spot, yellow moustachial area contrasting strongly with blackish colour; upperparts blackish, rump with greenish wash; tail blackish, edged olive; upperwing blackish, flight-feathers edged olive; throat bright yellow, contrasting bold blackish malar stripe; otherwise yellow below, with side of breast and flanks washed greenish; iris dark reddish; bill black; legs blackish-grey. Sexes alike. Juvenile is browner above than adult, washed brown on breast and flanks, and obscurely streaked below. Race *carrikeri* is smaller than nominate, more olive-greenish above, and lacks yellow supraloral. Voice. Song relatively simple, loud and often includes inflected or modulated notes at end, each song c. 1 second in duration, songs separated by 4–7 seconds, "Tweew Chéééw!" or "cheuu tch-weéé". Calls include high "zziiip".
Habitat. Edge of montane forest, and in moist highland thickets, overgrown pastures and second growth, and edges of Yungas forest; at 1200–3600 m.
Food and Feeding. Insufficient information on diet. Forages on and near ground. Usually found in pairs or family groups.
Breeding. Birds in breeding condition in Dec–Feb. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Given its abundance, and adequately large range, this species is considered not to be at any immediate risk. As it prefers edge habitats, it may benefit from disturbance of montane forests.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (1999), Hennessey *et al.* (2003), Paynter (1978), Remsen (1993), Remsen & Graves (1995a).

155. Fulvous-headed Brush-finch

Atlapetes fulviceps

French: Tohi à tête rousse **German**: Braunbart-Buschammer **Spanish**: Atlapetes Cabecirrufo

Taxonomy. *Emberiza fulviceps* d'Orbigny and Lafresnaye, 1837, Tacora [= Totora], Cochabamba, Bolivia. Sometimes considered to form a superspecies with *A. semirufus* and *A. personatus*; while last two may be closely related, present species believed not close to them but, rather, merely visually similar. Monotypic.
Distribution. Andes of Bolivia (from La Paz S to Tarija) and adjacent NW Argentina (S to Jujuy and Salta).

Descriptive notes. 17 cm; one bird 28·2 g. Head down to cheek, ear-coverts, side of neck and nape cinnamon, contrasting yellow patch on lores and yellow submoustachial area, latter bordered below by cinnamon malar stripe (entirely isolating yellow submoustachial area); upperparts green, upperwing and tail slate-grey with green fringes, upperwing-coverts greenish; yellow chin and throat, contrasting with cinnamon malar; underparts with olive breastband, flanks and crissum, yellow belly, on some breastband somewhat broken (giving more yellowish appearance in centre of breast); iris medium-brown; bill black; legs brownish. Sexes alike. Juvenile undescribed. Voice. Song, from low vegetation, tends to be relatively uniform, is short and explosive, with introductory note and then a note repeated 3–5 times, e.g. "tii'Chew-Chew-Chew!" or faster "twi-tew'tew'tew", sometimes lengthened to "pit-twee pit' Chew-Chew-Chew". Call a thin "zit"; alarm "pi ziue".
Habitat. Edge of semi-humid Yungas forest, undergrowth in moist open woodland, especially where alders (*Alnus*) present, also wooded ravines and older second growth; often associated with streams. Can be found at edge of *Polylepis* forests. Generally at 1500–3600 m; in winter apparently sometimes lower, possibly down to 400 m.
Food and Feeding. Insects and seeds recorded as eaten. Forages from just above ground to 3 m up in shrubbery. Also searches along thick moss-laden branches. Occasionally sallies out to catch insects. Forages singly and in pairs.
Breeding. Eggs in Jan in N Argentina (Jujuy). No other information.
Movements. Resident; some evidence that some move downslope, to as low as 400 m in elevation, in winter.
Status and Conservation. Not globally threatened. Locally fairly common. Has reasonably extensive range and is reasonably abundant within it, and there is no evidence for any declines in its numbers; this species is therefore considered not to be at any immediate risk.
Bibliography. Armani (1985), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Remsen *et al.* (1988), Ridgely & Tudor (1989).

156. Yellow-striped Brush-finch

Atlapetes citrinellus

French: Tohi citrin **German**: Schwarzbart-Buschammer **Spanish**: Atlapetes Amarillo

Taxonomy. *Buarremon* (*Atlapetes*) *citrinellus* Cabanis, 1883, near Chaquevil and San Xavier, Tucumán, Argentina. Monotypic.
Distribution. NW Argentina from Jujuy and Salta S through Tucumán to Catamarca.

Descriptive notes. 17 cm; one male 28 g. Distinctive brush-finch, often appearing somewhat small-billed and with complex head pattern. Has blackish forehead, becoming dark brownish-olive on crown and nape, contrasting bold yellow supercilium, whitish lower half of eyering contrasting with blackish lores to anterior ear-coverts, grizzled yellow on lower ear-coverts, contrasting bright yellow submoustachial region bordered below by wide blackish malar stripes which meet on chin, and yellow throat; upperparts greenish, upperwing and tail more blackish, flight-feathers and tail feathers edged greenish-yellow; entirely olive below, yellowest on central belly and undertail-coverts, washed greenish on flanks; iris dark reddish; bill black; legs greyish-black to flesh-coloured. Sexes alike. Juvenile apparently undescribed. VOICE. Song a simple and explosive "chip-pip' chew-chew-chew". Call "tsip".

Habitat. Typically encountered in alder (*Alnus*) woodland, and in undergrowth and borders of Yungas forest; found in old mature forest, as well as second growth. Recorded at elevations of 700–3100 m.

Food and Feeding. In dry and wet seasons eats mostly invertebrates, including beetles (Coleoptera), ants (Formicidae) and some other Hymenoptera, spiders (Araneae), and various unidentified invertebrates. Forages on and near ground. Generally in pairs and family groups.

Breeding. Egg dates in Nov in Tucumán; season likely extends to austral summer, thus Nov–Jan/Feb. Nest placed in small shrub; clutch 2–3 eggs, white with pinkish wash and brown spots, latter concentrated mostly around wide end. No other information.

Movements. Largely resident; moves downslope in winter in Tucumán.

Status and Conservation. Not globally threatened. Restricted-range species: present in Argentine and South Bolivian Yungas EBA. Common; most numerous in Tucumán, less common farther N. Range is reasonably large, and populations within that range also large, in addition to which there is no evidence of any real threat to its habitat; this species is therefore considered not to be at any immediate risk.

Bibliography. Armani (1985), Biancucci & Martin (2008), Blake & Rougès (2001), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Ortiz *et al.* (2011), Paynter (1978), Ridgely & Tudor (1989).

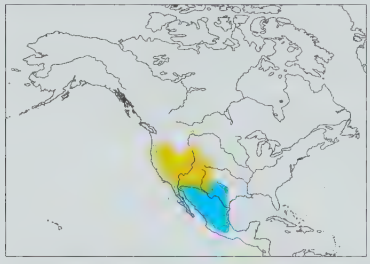
Genus *PIPILO* Vieillot, 1816

157. **Collared Towhee**

Pipilo ocai

French: Tohi à collier **German**: Halsband-Grundammer **Spanish**: Toquí Acollarado

Taxonomy. *Buarremon ocai* Lawrence, 1865, no locality = Las Vigas, west of Jalapa, Veracruz, Mexico.
Relationships of genus not clear, although generally placed close to several other, similarly proportioned tropical American genera (e.g. some *Aimophila*, *Atlapetes*, *Pyrgisoma* and *Melozone*). Commonly hybridizes with *P. maculatus* in N & E of range (mainly races *alticola* and *nigrescens*, *alticola* forming a hybrid swarm with adjacent populations of that species), but in Oaxaca *brunnescens* apparently sympatric with *P. maculatus* without interbreeding. Five subspecies recognized.
Subspecies and Distribution.
P. o. alticola (Salvin & Godman, 1889) – W Jalisco and extreme NE Colima, in W Mexico.
P. o. nigrescens (Salvin & Godman, 1889) – NC Michoacán (E to near Morelia), in C Mexico.
P. o. guerrerensis van Rossem, 1938 – Sierra Madre del Sur (in Guerrero), in SW Mexico.
P. o. ocai (Lawrence, 1865) – mountains of E Puebla and WC Veracruz, in EC Mexico.
P. o. brunnescens van Rossem, 1938 – C Oaxaca, in S Mexico.



Descriptive notes. 19·5–23 cm; 54·5–68 g. Large, long-tailed sparrow, adult with unstreaked underparts. Nominate race has black forehead with narrow white median line, rufous crown, long white supercilium from bill base back to side of nape, black lores and ear-coverts; nape, side of neck and upperparts, including upperwing and tail, olive-green, bend of wing bright yellow; throat and submoustachial region white, breast grey except for black pectoral band, broadest at centre, with flanks and undertail-coverts brownish, central abdomen paler; iris reddish-brown; bill black; legs pale horn-colour to flesh-coloured. Sexes similar in coloration. Juvenile has crown to upperparts brown, streaked darker, face blackish with dull yellow supercilium, throat and underparts yellowish, necklace of dark brown streaks, indistinct dusky streaks on belly, plain dusky-cinnamon flanks and undertail-coverts, iris brown. Race *alticola* has supercilium very narrow, broader black breastband than nominate, lacks median frontal stripe; *nigrescens* lacks white supercilium and frontal line, has very black face, white areas of head much reduced, giving hooded appearance, flanks tinged rusty; *guerrerensis* has narrow black breastband, pale undertail-coverts, brownish flanks; *brunnescens* is very like last, but greyer on flanks. Voice. Song variable, "clee-o-weet-ship-trrr" or "wheer-tseet-tseet-trrr, treee-chit-chit-chit", or "chree-tsit-tsit-trrr". Call note "zhree" or "jor-ee". Vocalizations rather similar to those of *P. maculatus*.
Habitat. Dense brush, including brushy fence rows and woodland edges, at 1500–3500 m; also coniferous forests above 2400 m.
Food and Feeding. Diet little known; probably mostly plant items (seeds, fruit) and small invertebrates, e.g. insects, spiders (Araneae) and millipedes (Diplopoda). Forages principally on ground and low in vegetation. Scratches in leaf litter. Generally singly and in pairs or family parties.
Breeding. Season early Mar (Michoacán) to late Mar through Jul, and in Sept (Guerrero). Nest a cup of dry grass, pine (*Pinus*) needles and twigs, lined with finer grasses, rootlets and hair, placed near ground usually in dense shrub. Clutch often 4 eggs, pale bluish with dark markings. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. No information on any changes in status.
Bibliography. Armani (1985), Binford (1989), Dawson (1950), Howell & Webb (1995), McCarthy (2006), Miller *et al.* (1957), Murray & Hardy (1981), Oberholser (1974), Ridgway (1901), Sibley (1950, 1954), Sibley & West (1958).

158. **Green-tailed Towhee**

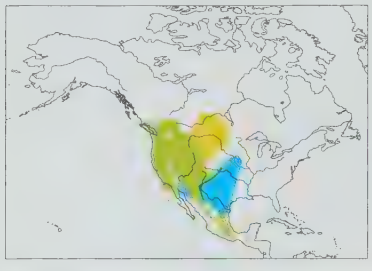
Pipilo chlorurus

French: Tohi à queue verte **German**: Grünschwanz-Grundammer **Spanish**: Toquí Coliverde

Taxonomy. *Fringilla chlorura* Audubon, 1839, no locality = Ross's Creek, about 20 miles [c. 32 km] south-west of Blackfoot, Bingham County, Idaho, USA.
Relationships of genus not clear, although generally placed close to several other, similarly proportioned tropical American genera (e.g. some *Aimophila*, *Atlapetes*, *Pyrgisoma* and *Melozone*). Monotypic.
Distribution. Breeds in W USA from SC & C Oregon, SE Washington, S Idaho, SC & SW Montana and Wyoming, possibly also WC South Dakota, S to SW & E California (principally E of Sierras), N & C Arizona, WC & NE New Mexico, and C Colorado, W Oklahoma and SW Texas, and in extreme NW Mexico (N Baja California); non-breeding S California E to W Texas, S in Mexico to S Baja California, Jalisco, Morelos, Hidalgo and Tamaulipas.
Descriptive notes. 15·7–18 cm; 21·5–39·4 g. Large, long-tailed sparrow, adult with unstreaked underparts. Has blackish forehead, rusty cap and white supraloral stripe, rest of head grey, contrasting white submoustachial stripe, black malar stripe, contrasting white throat; nape olive-green, upperparts, including upperwing and tail, olive-grey with some olive-green tinges, especially on fringes of wing and tail feathers, lesser upperwing-coverts more yellowish; underparts grey, becoming whitish on belly, buff wash on rear flanks and undertail-coverts; iris dark reddish-brown; bill blue-grey; legs dull brown to greyish. Sexes similar in plumage. Juvenile has crown, back, breast and flanks heavily streaked with dark brown, throat whitish, contrasting dark brown malar stripe, wings and tail with greenish cast. Voice. Song consists of lively clear, whistled notes, "wheeet clurr cheeeweee-churrr", or rapid wheezy "eet-ter-te-te-te-te-te-ti-si-si-seur". Call a sharp "keek", or a high-pitched "tseee"; also characteristic cat-like "meeoow".

Habitat. Diverse shrub communities (often following fire), including dry shrubby hillsides and second growth; dry shrubby desert locust (*Robinia neomexicana*) and small conifers, such as white fir (*Abies concolor*), Douglas-fir (*Pseudotsuga menziesii*) and ponderosa pine (*Pinus ponderosa*); at high elevations in New Mexico also Douglas-fir, locust, Gambel oak (*Quercus gambellii*), raspberry (*Rubus*), serviceberry (*Amelanchier*), aspen (*Populus*), pinyon pine (*Pinus*), juniper (*Juniperus*), and pine–oak. In shrub-steppe environments found in mixed-species shrub communities with common chokecherry (*Prunus virginiana*), big sagebrush (*Artemisia tridentata*), mountain mahogany (*Cercocarpus montanus*), juniper, snowberry (*Symphoricarpus*), manzanita (*Arctostaphylos*) and snowbush (*Ceanothus*). In non-breeding quarters found in dense mesquite (*Prosopis*) along desert washes.
Food and Feeding. Feeds primarily on insects and other small animal items, probably augmented with seeds, and some fruit when available. In winter, probably takes variety of fruits, seeds and buds, and insects; visits feeders. Forages principally on ground and low in vegetation. Especially in winter, uses double-scratch technique in which the bird remains stationary while scratching backwards with both feet simultaneously. Generally alone or in pairs; small groups outside breeding season.
Breeding. Season May to early Jul In Utah, from Apr in S of range, and sometimes not until Jun in high-elevation sites; probably double-brooded. Monogamous. Territorial. Nest built in 2–5 days, a large and deep, thickset cup made from stems, bark, twigs and grass, lined with finer materials such as rootlets and animal hair, placed on ground or up to 1 m above it in small bush or tree, most in sagebrush. Clutch 2–5 eggs, usually 3 or 4, pale blue with reddish speckling concentrated about wide end; incubation by female, period 12 days; chicks fed by both parents, nestling period 11–14 days. Nests parasitized very rarely by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migratory; migrates at night. Spring migration Feb–May. Arrival in S breeding areas begins in mid-Mar, in N part of range in first half May; passage in SE Arizona heaviest during last two weeks of Apr. Strong evidence of a short post-breeding moult migration to other habitats in order to moult and gain fat; in SW parts of range moves up to mountain meadows, which are quite productive during late-summer period; such upslope movements may begin by late Jun, usually Jul and into Aug. Departure from N breeding grounds mainly in Aug and Sept, some lingering to Oct; peak S-bound movements generally from Sept to early Oct, and arrival in Mexico by early Sept, at wintering sites farther S by Oct. Casual in spring N to NW Washington, British Columbia and Saskatchewan. Vagrant E of range throughout most US states, also Canadian provinces, mainly in autumn and winter. Winter vagrant in Cuba.
Status and Conservation. Not globally threatened. Fairly common. Populations evidently stable. Adversely affected by habitat degradation, such as destruction of sagebrush and reseeding with grasses for livestock. In contrast, logging at higher elevations can create suitable habitat.
Bibliography. Armani (1985), Beadle & Rising (2002), Bent & Austin (1968), Dobbs *et al.* (1999), Jehle *et al.* (2006), LeGrand (2005), Leukering (2000), McCarthy (2006), Miller *et al.* (1957), Morton (1991), Oberholser (1974), Phillips *et al.* (1964), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Sibley (1955a), Urban (1959), Zink (1988), Zwartjes & Farley (1998).

159. **Spotted Towhee**



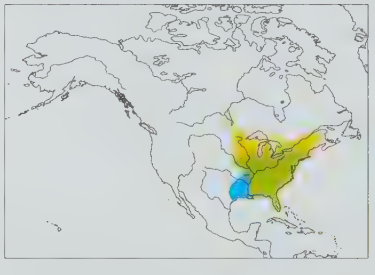
Pipilo maculatus

French: Tohi tacheté **German**: Fleckengrundammer **Spanish**: Toquí Moteado
Other common names: Rufous-sided Towhee (when treated as conspecific with *P. erythrophthalmus*); Socorro Towhee (*socorroensis*); Olive-backed Towhee ("*macronyx* group"); San Clemente Spotted Towhee (*clementae*)

Taxonomy. *Pipilo maculata* Swainson, 1827, Real del Monte, Hidalgo, Mexico.
Relationships of genus not clear, although generally placed close to several other, similarly proportioned tropical American genera (e.g. some *Aimophila*, *Atlapetes*, *Pyrgisoma* and *Melozone*). Present species sometimes considered conspecific with *P. erythrophthalmus*, with which it hybridizes in Great Plains of USA; commonly hybridizes also with *P. ocai* in Mexico. S races *macronyx*, *vulcanorum* and *oaxacae* ("*macronyx* group") sometimes treated together as a separate species, and island race *socorroensis* sometimes treated as a further full species. Race *griseipygius* intergrades with *montanus*, and *vulcanorum* intergrades with nominate. Geographical variation partially clinal, amount/extent of white dorsal spots and amount of white in tail decreasing from N to S in C Rocky Mts (also from E to W in plains of USA), and, conversely, dorsal spotting increasing from British Columbia S along Pacific coast to NW Baja California. Race *oaxacae* poorly differentiated, perhaps better merged in *chiapensis*. Twenty extant subspecies recognized.
Subspecies and Distribution.
P. m. oregonus Bell, 1849 – extreme SE Canada (SW British Columbia) S in W USA to SW Oregon; non-breeding S to S California.
P. m. falcinellus Swarth, 1913 – interior & SW Oregon S to California (W & SE slopes of Sierra Nevada).
P. m. falcifer McGregor, 1900 – coastal N California (S to Santa Cruz and San Benito Counties).
P. m. megalonyx S. F. Baird, 1858 – coastal S California from Monterey and Kern Counties S, including Santa Cruz I, to extreme NW Mexico (NW Baja California S to 32° N).
P. m. clementae Grinnell, 1897 – Santa Rosa, Santa Catalina and San Clemente Is, off SW California.
P. m. umbraticola Grinnell & Swarth, 1926 – N Baja California (32° N S to 30° N).
P. m. magnirostris Brewster, 1891 – Sierra de la Laguna, S Baja California Sur, Mexico.
P. m. socorroensis Grayson, 1867 – Socorro I, off W Mexico.
P. m. arcticus (Swainson, 1832) – breeds in SW Canada (C Alberta and C Saskatchewan) S in USA (E of Rocky Mts) to SE Wyoming, NE Colorado, C Nebraska and NW Kansas; non-breeding mainly S USA from C Arizona (rare) and SW New Mexico E to C Iowa, W Missouri and S Texas, S in Mexico to C Chihuahua and C Nuevo León.

On following pages: 160. Eastern Towhee (*Pipilo erythrophthalmus*); 161. Prevost's Ground-sparrow (*Melozone biarcuata*); 162. White-eared Ground-sparrow (*Melozone leucotis*); 163. Rusty-crowned Ground-sparrow (*Pyrgisoma kieneri*); 164. Canyon Towhee (*Pyrgisoma fuscum*); 165. White-throated Towhee (*Pyrgisoma albicolle*); 166. California Towhee (*Pyrgisoma crissale*); 167. Abert's Towhee (*Pyrgisoma aberti*).

P. m. curtatus Grinnell, 1911 – N Great Basin in SW Canada (interior S British Columbia) and NW USA (N Idaho S to NE California, C Nevada and SE Idaho); non-breeding S to SE California and SE Arizona.
P. m. montanus Swarth, 1905 – breeds in S Great Basin and Rocky Mts region from SE California E to SE Nevada, N Utah, NC Colorado, NE New Mexico and W Oklahoma, S to SC Arizona and N Mexico (NE Sonora and NW Chihuahua); non-breeding S to N Sonora, C Chihuahua and CS Texas.
P. m. gaigei Van Tyne & Sutton, 1937 – S USA (E & SE New Mexico and W Texas) and adjacent N Mexico (N Coahuila).
P. m. griseipygius van Rossem, 1934 – Sierra Madre Occidental from SW Chihuahua (29° N) S through E Sinaloa and W Durango to NE Nayarit and W Zacatecas (W Mexico).
P. m. orientalis Sibley, 1950 – Sierra Madre Oriental of Mexico from SE Coahuila, C Nuevo León and SW Tamaulipas S to NE Guanajuato, Querétaro and N Hidalgo (E Mexico).
P. m. maculatus Swainson, 1827 – highlands of SE Tlaxcala, WC Veracruz and E Puebla, in E Mexico.
P. m. macronyx Swainson, 1827 – mountains on W & SW sides of Valley of Mexico (in E Michoacán, México, NW Morelos and Distrito Federal).
P. m. vulcanorum Sibley, 1950 – mountains on SE side of Valley of Mexico (in México, NE Morelos, SW Tlaxcala and W Puebla).
P. m. oaxacae Sibley, 1950 – highlands of N & C Oaxaca, in S Mexico.
P. m. chiapensis van Rossem, 1938 – mountains of C Chiapas, in SE Mexico.
P. m. repetens Griscom, 1930 – SE Chiapas (Volcán Tacaná) and Pacific cordillera of Guatemala.



Descriptive notes. 17·7–21·3 cm; 30·6–49 g. Large, long-tailed sparrow with white spots on upperwing-coverts. Male nominate race has head and chest black, upperparts dark brownish-olive to grey-tinged olive-brown, mantle and scapulars with white spots; upperwing and tail similar to back in colour, wing-coverts tipped white (forming two broken wingbars), tertials edged white, outer tail feathers tipped white, outermost also edged white; lowermost breast and belly white, flanks tawny-rufous, becoming somewhat paler cinnamon-rufous on undertail-coverts; iris red; bill blackish; legs flesh-coloured. Female is similar to male, but hood browner, upperparts duller and greyer. Juvenile has head and upperparts dark brown, feathers edged and tipped brighter brown, wing-coverts prominently tipped buff, underparts whitish with dark brown streaks, streaking heaviest on lower throat and breast, with cinnamon wash on flanks and vent, brownish eyes; rufous flank feathers emerge in early moults. Races differ mainly in plumage tones and markings, also in degree of sexual dichromatism, which is most extreme in NE (*arcticus*), least marked in coastal populations (particularly *oregonus*): *macronyx* is paler and more greenish above than nominate, spots on upperparts and tail yellow (not white), bend of wing yellow; *vulcanorum* is like previous, but upperparts duller olive and clearly streaked blackish, with spots larger and paler yellow; *oaxacae* is like nominate, but upperparts paler and browner, white spots larger, tertials with more extensive white on edges; *chiapensis* is very like last, perhaps slightly darker above, and spots tending to be slightly buff-tinged (less white); *repetans* is like preceding two, but upperparts more blackish-olive (less buff-brown) and spots whiter; *oregonus* has blackest upperparts, with relatively small white spots more restricted in extent (not extending far on to mantle); *megalonyx* is very like previous, but spots slightly smaller; *falcinellus* resembles previous, but white spots on average larger, rump slightly paler and greyer, hind claw on average shorter; *falcifer* is similar to last, but white spots smaller; *clementae* is similar to *megalonyx*, but bill generally a little larger, upperparts (especially female) slightly paler; *umbraticola* also is similar to *megalonyx*, but bill generally slightly smaller, upperparts (especially female) slightly darker; *magnirostris* likewise resembles *megalonyx*, but flanks paler, more tawny-buff, has more white in tail, also slightly shorter wing and tail, on average slightly longer bill and hind claw; *socorroensis* is smaller than other races, both sexes with head to breast and upperparts dark olivaceous grey, spots relatively small; *arcticus* has upperparts dull olive-tinged black, spots on mantle and scapulars large and extensive, female greyish-brown where male black; *montanus* is like previous, but upperparts purer black, with little olive tint; *curtatus* is like last, but upperparts generally still blacker, with even less olivaceous tinge; *gaigei* is similar to *montanus*, but white spots on upperparts slightly smaller, rump greyer (less black); *griseipygius* is similar to previous, but upperparts more greyish-black, rump slightly more olivaceous (less grey), flanks slightly darker; *orientalis* also resembles *gaigei*, but upperparts more blackish, rump with more black admixed, flanks darker. Voice. Song variable, but typically 2 "chip" notes followed by a trill, "chup chup zeeeeeeee"; in Mexico "chip-chip-trrrr"; on US Pacific coast a dry buzz, often lacking introductory notes. Call note a nasal "pshew" or "meeew", or quiet "tseep"; in Mexico "jor-eee".
Habitat. Dense deciduous or mixed thickets; high-altitude mixed forest and pine–oak–fir (*Quercus–Pinus–Abies*) forest with brushy understorey; shrubs such as junipers (*Juniperus*) and *Baccharis*, brushy gulleys with madrones (*Arbutus*), *Rubus*, *Rosa*, ceanothus (*Ceanothus*), hawthorn (*Crataegus*), shrubby composites and ferns, also slopes with ceanothus and young pines. In N Great Plains found also in riparian deciduous thickets. From near sea-level to 3355 m.
Food and Feeding. Diet in breeding season primarily insects, including beetles (Coleoptera), crickets (Orthoptera), bugs (Hemiptera, including homopterans), Hymenoptera, flies (Diptera), caterpillars and moths (Lepidoptera); also spiders (Araneae), millipedes (Diplopoda) and sowbugs (Isopoda); also plant seeds, especially of *Polygonum*, *Stellaris*, *Rubus* and *Cirsium*, also of oats (*Avena*), wheat (*Triticum*) and nightshade (*Solanum*). Details of diet vary geographically. In non-breeding season takes more plant material, mainly seeds, acorns and fruits. Forages principally on ground and low in vegetation, under cover, searching beneath litter; occasionally higher. Scratches among litter; also gleans items from vegetation. Generally singly and in pairs; outside breeding season also in small groups.
Breeding. Season mid-Apr to late Jul in most of USA, although song and territorial behaviour by early Mar in coastal California, and breeding activity from early Jan in Mexico; double-brooded. Monogamous. Territorial. Nest built by female, a bulky cup of dry grass, dead leaves, bark and stems, soft lining of fine grass, rootlets and animal hair, usually (90% of nests) placed on ground, often in depression under bush, fallen branch or log, occasionally up to 2 m (rarely 5·5 m) above ground in shrub, vine or small tree. Clutch 2–5 eggs, normally 3 or 4, white to pinkish or pale blue with darker reddish, brownish or purplish speckling; incubation by female, period 12–14 days; chicks fed by both parents, nestling period 9–11 days. Nests parasitized by both Brown-headed (*Molothrus ater*) and Bronzed Cowbirds (*Molothrus aeneus*).
Movements. NE interior populations (race *arcticus*) migratory, and coastal, insular and Mexican populations resident; those in Great Basin and S Rocky Mts move short distances or perform altitudinal movements. N-bound movements through C California between late Mar and early May; spring migration peak from last week Apr to mid-May in interior W and into Canadian Prairies. Autumn migration late Aug to early Dec, peak early Oct, in C California; arrival in wintering areas by early to middle Sept, continuing into Dec. Race *arcticus* recorded as vagrant E to Atlantic coast of North America (Quebec S to Florida); one record from Britain considered not to have involved a wild individual.
Status and Conservation. Not globally threatened. Generally common to fairly common. Race *consobrinus*, confined to Guadalupe I, off Baja California, extinct. Race *clementae* considered a "California Species of Special Concern" in highest degree of priority; threatened by habitat loss, caused partially by introduced feral pigs. Habitat loss through overgrazing can lead to rapid extirpation of local populations, especially on islands. In contrast, this species has recently extended its US breeding range E to Oklahoma.
Bibliography. Armani (1985), Beadle & Rising (2002), Bent & Austin (1968), Byers, Curson & Olsson (1995), Davis (1957a, 1957b, 1958, 1960b, 1961), Dinzl (1990), Ellison (1999), Gardali & Nur (2006), Greenlaw (1996b), Greenlaw & Engstrom (2001), Haiiser (1960), Irwin (1989), Jackson (1955), Kroodsma (1971), McCarthy (2006), McKay *et al.* (2009), Murray & Hardy (1981), Palmer-Ball & Cassell (1990), Pyle (1997), Pyle & Henderson (1991), Ridgway (1901), Rising & Beadle (1996), Roberts (1969), Rowley (1962), Shuford & Gardali (2008), Sibley (1950, 1954), Sibley & West (1958, 1959), Small (2005), Stubblefield & Rising (2002), Urban (1959), Wiggins *et al.* (2004).

160. Eastern Towhee
Pipilo erythrophthalmus

French: Tohi à flancs roux **German**: Rötelgrundammer **Spanish**: Toquí Flanquirrufo
Other common names: Rufous-sided Towhee (when treated as conspecific with *P. maculatus*); White-eyed Towhee (Florida)

Taxonomy. *Fringilla erythrophthalma* Linnaeus, 1758, South Carolina, USA.
Relationships of genus not clear, although generally placed close to several other, similarly proportioned tropical American genera (e.g. some *Aimophila*, *Atlapetes*, *Pyrgisoma* and *Melozone*). Present species sometimes considered conspecific with *P. maculatus erythrophthalmus*, with which it hybridizes in Great Plains of USA. Races intergrade, making delimitation difficult. Geographical variation in biometrics, plumage colour and iris colour largely clinal: average wing length decreases slightly from NW to SE, and lengths of middle toe, tarsus and bill increase from N to SE; individuals N of a line joining C Alabama, N Georgia, NW South Carolina and SE North Carolina are red-eyed, whereas those S of it have white or pale straw-coloured eyes (a narrow cline in eye colour from S Alabama NE to SE North Carolina, with populations in Georgia and S South Carolina variable). Four subspecies recognized.
Subspecies and Distribution.
P. e. erythrophthalmus (Linnaeus, 1758) – breeds in S Canada (S Manitoba, S Ontario and extreme S Quebec) and E USA (N Minnesota E to N Vermont, C New Hampshire and SW Maine, S to NE Oklahoma, N Arkansas, S Tennessee, NE Georgia, NW South Carolina, C North Carolina and Virginia); non-breeding mainly from Nebraska, Wisconsin, S Michigan, extreme S Ontario, Pennsylvania, S New York and Massachusetts S to Oklahoma, CS & SE Texas, Gulf Coast and SC Florida.
P. e. canaster A. H. Howell, 1913 – NE Louisiana, NW Mississippi, SW Tennessee, N Alabama, N Georgia, C South Carolina and W North Carolina S to Gulf Coast (CS Louisiana E to NW Florida), EC Alabama, SE Georgia and coastal South Carolina.
P. e. rileyi Koelz, 1939 – SE Virginia, coastal North Carolina and coastal South Carolina S to SE Alabama, SE Georgia and N Florida; non-breeding also W & C Florida.
P. e. alleni Coues, 1871 – Florida.

Descriptive notes. 17·3–20·6 cm; 32·1–52·3 g. Large, long-tailed sparrow, adult with unstreaked underparts, rufous flanks, and white at base of primaries. Male nominate race has black head to breast and upperparts, including upperwing and tail; white at base of primaries, white on leading edges of middle primaries, white edges of tertials; outer three rectrices with large white area at tip, outermost also with white edge; lowermost breast and belly white, flanks orange-rufous, undertail-coverts buff; iris bright red; bill black; legs pinkish. Female is like male, but rich brown where male black. Juvenile has head and upperparts dark brown, feathers edged and tipped brighter brown, throat off-white, underparts pale buffish, breast and flanks streaked dark brown, vent warm buff, eyes brown; rufous flank feathers emerge in early moults. Race *alleni* is small, with intermediate bill size, pale eyes, and little white in tail; *rileyi* is medium-sized, large-billed, with variable eye colour, and less white in tail than nominate; *canaster* is large, large-billed, pale-eyed (not so pale as *alleni*), and has intermediate amount of white in tail. Voice. Song a distinctive loud, ringing "drink your teeeee", or "drink teeeee", the "teeeee" part usually louder than the other elements, and the "your" lower; variable. Call an emphatic "chee-wink, joreee" or simply "wink".
Habitat. Dense deciduous or mixed thickets, often second-growth thickets, young jack pines (*Pinus banksiana*), and edges of oak (*Quercus*) forest; scrub palmetto (*Sabal palmetto*) in S. In mountains, found in oldfields, oak–hickory (*Quercus–Carya*), white oak (*Quercus alba*) savanna, and in brushy clearings in spruce–fir (*Picea–Abies*) habitat. Breeds from sea-level to 1980 m. In non-breeding season found also in dense thickets with well-developed understorey; sometimes at feeders in residential areas.
Food and Feeding. During breeding season feeds primarily on insects and other small animal items, probably augmented with seeds and berries when available. In winter probably a variety of fruits, seeds and buds, and also, when available, insects. Forages principally on ground or low in vegetation. Especially in winter, uses a double-scratch technique, in which the bird remains stationary while scratching backwards with both feet simultaneously.
Breeding. Season early Apr to late May, and again to early Aug; double-brooded. Monogamous. Territorial. Nest built by female, is a bulky cup composed of stems, dry grass, bark and twigs, and lined with finer material such as rootlets, fine grasses and animal hair, placed on ground, usually in depression beneath a bush, a fallen branch or a log, occasionally in a shrub, vine or small tree, rarely to 5·5 m up. Clutch 2–6 eggs, most commonly 3 or 4, quite variable, whitish, pale blue or pinkish with darker spots in brown, blackish or rusty; incubation by female, period 12 days; chicks fed by both parents, nestling period 10–11 days. Common host of Brown-headed Cowbird (*Molothrus ater*).
Movements. N populations migratory, far S ones resident, others partially migratory. Spring migration late Apr through early May, although active migration noted into late May in NE. Post-

breeding departure from N begins Sept, with arrival in wintering areas as early as mid-Sept; throughout much of N part of range, however, S-bound migrants seen late Sept to mid-Oct, and arrivals in wintering areas continue into Nov. Nominate race recorded casually in winter NE to Quebec, New Brunswick, Nova Scotia and Newfoundland and W to Montana and Colorado; vagrant W to Idaho and Arizona. One record of vagrant in W Europe (Lundy, in SW England), probably ship-assisted. Race *alleni* wanders casually S to Florida Keys.
Status and Conservation. Not globally threatened. Fairly common to locally common. Probably influenced by human activities even in pre-colonial times. Following clearance of forests, early successional vegetation provides good habitat for this species. In some regions, habitat destruction following development has depressed numbers, and populations in SE declined in 20th century. Commonly nests behind coastal dunes; as these areas are developed for cottages and recreation, towhee habitat is destroyed.

Genus *MELOZONE* Reichenbach, 1850

161. **Prevost's Ground-sparrow**

Melozone biarcuata

French: Tohi à face blanche **German**: Weißwangen-Grundammer **Spanish**: Toquí Cuatro-ojos
Other common names: White-faced Ground-sparrow; Chiapas Ground-sparrow (*hartwegi*); Cabanis's Ground-sparrow (*cabanisi*)

Taxonomy. *Pyrgita biarcuata* Prévost and Des Murs, 1846, no locality = "California" and Guatemala.
Formerly considered close to, and has been considered conspecific with, *Pyrgisoma kieneri*, but differs in both adult and juvenile plumages. Race *cabanisi* sometimes considered to represent a separate species. Race *hartwegi* often treated as a synonym of nominate. Three subspecies recognized.
Subspecies and Distribution.
M. b. hartwegi Brodkorb, 1938 – SE Mexico (Chiapas).
M. b. biarcuata (Prévost & Des Murs, 1846) – highlands of Guatemala, W Honduras and El Salvador.
M. b. cabanisi (P. L. Sclater & Salvin, 1868) – highlands of C Costa Rica.

Descriptive notes. 15–17·5 cm; 24·8–32 g. A fairly large sparrow, adult with distinctive head pattern. Nominate race has blackish forehead, rusty crown to hindneck, white side of face with rusty to blackish posterior edge of ear-coverts; upperparts, including upperwing and tail, olive-brown, flight-feathers darker brown, all wing feathers with inconspicuous narrow paler edges; whitish below, throat to upper breast washed light buff, side of breast grey, flanks greyish-buff, undertail-coverts cinnamon-buff; iris dark red-brown; bill black; legs greyish-brown to pinkish. Sexes similar in coloration. Juvenile lacks distinctive head pattern, has head and upperparts buffish-brown, ear-coverts darker, throat creamy buff, underparts whitish, breast and flanks streaked dark brown, lower flanks and undertail-coverts cinnamon-buff (similar to adult), bill horn-coloured. Race *hartwegi* is very like nominate, but upperparts more greyish-olive; *cabanisi* has brighter rufous crown and nape, this colour extending over central and rear ear-coverts, edges of ear-coverts black, large white spot between eye and bill, broad white eyering (also extending slightly behind eye), black moustachial stripe, white submoustachial and thin black malar stripe, blackish patch on central breast. Voice. Song consists of a high, thin, staccato sputter of buzzy notes and a slow trill, followed by 3–4 clear whistles. Call a weak, high, staccato "tsiting" or a high, thin "pseeer".
Habitat. Edges of tropical deciduous montane evergreen forest, also secondary forest, and in undergrowth and thickets of tall shrubby second growth, coffee plantations, blackberry (*Rubus*), bracken (*Pteridium*) and hedgerows. From near sea-level to 2900 m, usually below 1850 m.
Food and Feeding. Diet mainly small arthropods and seeds. Forages usually on or near ground. Scratches on ground among leaf litter in search of arthropods. Singly and in pairs.
Breeding. Nests in late Apr in El Salvador and May–Sept in Costa Rica. Nest a cup of dead leaves and grasses, lined with finer grasses, generally placed low down (0·25–2 m above ground) in bush or grass tussock, sometimes in small tree. Clutch 2–3 eggs, whitish, with reddish-brown to lilac spotting concentrated around wider end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally fairly common. Common on Pacific slope of Guatemala and in Valle Central of Costa Rica, and fairly common in Caribbean subtropics; uncommon to locally fairly common in interior highlands of Honduras.
Bibliography. Armani (1985), Danner *et al.* (2008), David & Gosselin (2002b), Dickey & van Rossem (1938), Dunning (2008), Griscom (1932), Howell & Webb (1995), Land (1970), Miller *et al.* (1957), Monroe (1968), Ridgway (1901), Stiles & Skutch (1989).

162. **White-eared Ground-sparrow**

Melozone leucotis

French: Tohi oreillard **German**: Weißohr-Grundammer **Spanish**: Toquí Orejiblanco
Other common names: Salvin's Ground-sparrow (*occipitalis*)

Taxonomy. *Melozone leucotis* Cabanis, 1861, Costa Rica.
Three subspecies recognized.
Subspecies and Distribution.
M. l. occipitalis (Salvin, 1878) – Pacific coast of S Mexico (Chiapas), Guatemala and El Salvador (Volcán de San Salvador).
M. l. nigrior W. deW. Miller & Griscom, 1925 – NC highlands of Nicaragua.
M. l. leucotis Cabanis, 1861 – highlands of Costa Rica.

Descriptive notes. 17–19 cm; 39·9–43 g. A large, chunky sparrow with large feet, and much black on fore parts. Nominate race has head mostly black, large bright whitish spot on lores, broken white eyering, white patch on ear-coverts, thin yellow eyestripe behind eye, broader yellow line below ear-coverts; upperparts, including upperwing and tail, dark olive-green, wing feathers edged brighter olive; throat and broad central part of upper breast black, side of breast grey, belly whitish, flanks to undertail-coverts cinnamon-tinged buffish-brown; iris reddish-brown; bill black; legs horn-coloured. Sexes similar in coloration. Juvenile has black of head less extensive, facial markings indistinct, upperparts scaled with sooty grey, upperwing-coverts with cinnamon-buff edges, belly yellowish-white, breast to flanks streaked dark, bill yellowish. Race *nigrior* resembles nominate, but pale collar on lower throat even thinner and inconspicuous, black on breast more extensive; *occipitalis* is distinctive, has grey median crownstripe, broader yellow postocular stripe curving down to side of neck, white breast with bold black central spot on lower part. Voice. Song consists of explosive staccato notes and loud hoarse whistles. Call a weak, high, piercing "tsip".
Habitat. Found in montane evergreen forest, dark thickets, moist ravines, low scrubby growth, at edges of corn fields and other clearings, and forest edge; prefers thickets on edge of open land. At 500–2000 m.
Food and Feeding. Insects, spiders (Araneae) and other arthropods, also seeds. Forages on and near ground. Hops on ground, frequently flicking its tail. Gleans arthropods from vegetation, and seeds from leaf litter; often uses two-foot scratching technique to expose items on ground. Usually in pairs or family parties.
Breeding. Season Apr–Jul in Costa Rica. Nest a large bulky bowl of dead leaves, stems and thin twigs, lined with finer grasses and other material, placed on ground or up to 0·7 m above it, well hidden among plants. Clutch 2–4 eggs, most commonly 2, white to pale blue with cinnamon or brownish spotting. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally fairly common. Uncommon in El Salvador, where much of its habitat has been destroyed.
Bibliography. Anderson *et al.* (1998), Armani (1985), Dickey & van Rossem (1938), Dunning (2008), Griscom (1932), Howell & Webb (1995), Land (1970), Miller *et al.* (1957), Ridgway (1901), Sassi (1939), Stiles & Skutch (1989), Winnett-Murray (1985).

Genus *PYRGISOMA* Bonaparte, 1850

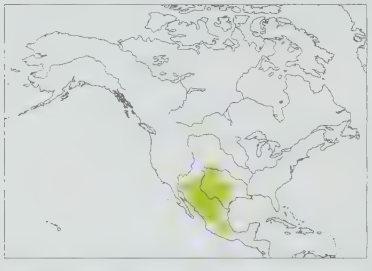
163. **Rusty-crowned Ground-sparrow**

Pyrgisoma kieneri

French: Tohi de Kiener **German**: Rostnacken-Grundammer **Spanish**: Toquí Nuquirrufo
Other common names: Ground Sparrow, Bonaparte's Ground-sparrow, Rusty-crowned Sparrow

Taxonomy. *Pyrgisoma kieneri* Bonaparte, 1850, Am[erica] occ[identale] = San Blas, Nayarit, Mexico. Sometimes placed in genus *Melozone*. Formerly considered close to, and has been considered conspecific with, *Melozone biarcuata*, but differs in both adult and juvenile plumages. Geographical variation appears to be slight, but poorly documented; race *grisius* often considered synonymous with nominate. Proposed race *obscurius* (described on basis of a single specimen from SW of Sola de Vega, in SW Oaxaca) appears to differ little from *rubricatum*, with which it is synonymized. Three subspecies provisionally recognized.
Subspecies and Distribution.
P. k. grisius (van Rossem, 1933) – extreme SE Sonora and N Sinaloa, in W Mexico.
P. k. kieneri Bonaparte, 1850 – extreme S Sonora, Sinaloa, W Durango, Nayarit, W Jalisco and Colima, in W Mexico.
P. k. rubricatum (Cabanis, 1851) – C & SW Mexico from S Guanajuato and Michoacán E to Morelos, SW Puebla, Guerrero and W Oaxaca.

Descriptive notes. 15–17·5 cm; 31·9–41·3 g. A fairly large sparrow with dark breast spot. Nominate race has blackish lower forehead, greyish forecrown and rusty hindcrown, nape and side of neck; side of face dull brownish with white supraloral and eyering; upperparts, including upperwing and tail, brownish-grey; throat white, underparts whitish, black central breast spot, olive-grey flanks, rusty undertail-coverts; iris dark drown; bill blackish; legs flesh-coloured. Sexes similar in coloration. Juvenile lacks head pattern of adult, has head and upperparts dusky brown, wing feathers with buffish edges, dusky malar streak, similar to adult below, but throat and breast with dark brown streaks. Races differ mainly in size and in plumage tone: *grisius* is greyer above than nominate, with rufous on head and undertail-coverts paler; *rubricatum* is smaller than nominate, with smaller bill and weaker feet and tarsi, often somewhat brighter rufous hindcrown and nape. Voice. Song a few doubled notes running into accelerating series of chipping notes, "tsi tsi sssit s'weet sweet chi-chi-chi-chi-chi". Call a thin "dzzzzzziu".
Habitat. Arid to semi-arid brushy woods, thorn-forests, and arid subtropical oak (*Quercus*) and juniper (*Juniperus*), also sometimes in brushy hedges. Sea-level to 2000 m.
Food and Feeding. Seeds and arthropods. Forages on and near ground, sometimes also in low shrubbery. Can be difficult to see. Often scratches at ground with both feet together. Singly and in pairs.



Breeding. Breeding recorded in Jun and early Jul. Nest a large bulky cup, usually with base of dried leaves, supplemented with dried grasses, lined with finer grasses and cattle hair, generally placed 1–2 m up (Morelos) or placed on or near ground. Clutch usually 2–3 eggs, rarely 4 (of eleven nests in Morelos, ten had 2 eggs), pale blue with reddish markings. Commonly parasitized by cowbirds (*Molothrus*).
Movements. Sedentary.
Status and Conservation. Not globally threatened. Status uncertain, apparently uncommon; race *rubricatum* very uncommon in Guerrero and Oaxaca, but in Morelos said to be the most abundant of the resident sparrows. Species perhaps merely difficult to find.
Bibliography. Armani (1985), Binford (1989), Dunning (2008), Howell & Webb (1995), Miller *et al.* (1957), Ridgway (1901), Rowley (1962), Russell & Monson (1998).

164. Canyon Towhee

Pyrgisoma fuscum

French: Tohi des canyons **German**: Braunrücken-Grundammer **Spanish**: Toquí Pardo
Other common names: Brown Towhee (when treated as conspecific with *P. crissale*)

Taxonomy. *Pipilo fusca* Swainson, 1827, Temascaltepec, México, Mexico.
Formerly placed in genus *Pipilo* and sometimes in *Melozone*. Molecular analysis indicates that present species and *P. albicolle* are sister-taxa. Previously treated as conspecific with *P. crissale*. Geographical variation rather weak, and largely clinal, with much intergradation. Proposed race *aimophilum* (described from Fort Davis, Texas) treated as a synonym of *texanum*. Ten subspecies recognized.
Subspecies and Distribution.
P. f. mesoleucum (S. F. Baird, 1854) – S USA from Arizona E through New Mexico and W Texas, and N Mexico S to N Sonora (except NW coast) S to 30° N and NW Chihuahua S to 31° N.
P. f. mesatum (Oberholser, 1937) – SE Colorado, NE New Mexico and NW Oklahoma.
P. f. texanum (van Rossem, 1934) – W & C Texas S to N Mexico (NW Coahuila).
P. f. intermedium (Nelson, 1899) – C & S Sonora S to N Sinaloa (El Fuerte and Yecorato).
P. f. jamesi (C. H. Townsend, 1923) – Tiburón I, off CW Sonora, Mexico.
P. f. perpallidum (van Rossem, 1934) – WC Mexico in Sierra Madre Occidental and E foothills (from Chihuahua S through Durango to Nayarit, N Jalisco and SW Zacatecas).
P. f. potosinum (Ridgway, 1899) – C Mexico from N Coahuila, W Nuevo León and SW Tamaulipas S to E Zacatecas, W & C San Luis Potosí, NE Jalisco, Guanajuato and C & S Querétaro.
P. f. fuscum (Swainson, 1827) – Nayarit S to Colima, E through Jalisco and Michoacán, to Morelos, Mexico City, W Veracruz and NC Guerrero.
P. f. campoi (R. T. Moore, 1949) – Hidalgo, Puebla and W Veracruz, in E Mexico.
P. f. toroi (R. T. Moore, 1942) – Tlaxcala E to W Veracruz, S to Puebla and N Oaxaca.

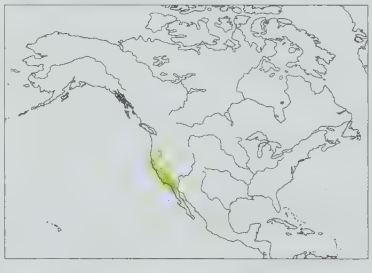
Descriptive notes. 18·5–22 cm; 36·6–52·5 g. Large, long-tailed sparrow with mostly grey-ish-brown plumage. Nominate race is grey-brown above, very slightly rufous-tinged crown contrasting with somewhat darker brownish-grey upperparts; foreface tinged buffish, ear-coverts spotted and streaked dark brown; throat light orange-buff, outlined with thin brown spots or streaks; underparts pale greyish, breast with dark brown central spot, flanks tinged buff-brown, crissum dull dark cinnamon; iris brown; bill horn-coloured, lower mandible paler; legs light brown. Sexes similar in plumage. Juveniles is like adult, but crown lacks rusty tone, upperwing-coverts tipped pinkish-buff (forming one or two indistinct wingbars), and throat, breast and flanks are spotted brown. Races differ mainly in crown colour and in general plumage tone: *toroi* is paler in coloration than nominate; *campoi* is similar to previous, but greyer; *mesoleucum* has rufous wash on crown, and is paler than nominate, especially on foreface and underparts; *mesatum* has crown brown with dull rufous wash, upperparts pale greyish-brown; *texanum* has little rufous in crown, and upperparts are greyish-brown with tawny tinge; *intermedium* has crown dark reddish-brown, back greyish brown, sides and flanks greyish-brown, throat pale buff, crissum pale cinnamon; *jamesi* is smaller and paler than previous, has crown pale reddish-brown, back pale brownish-grey, sides and flanks pale grey, and throat white with pale buff tinge; *perpallidum* has crown bright rusty brown, back greyish-brown, sides and flanks greyish-brown and crissum cinnamon; *potosinum* crown is cinnamon-rufous, upperparts pale brownish-grey, throat pale buffy, flanks tinged with brown. Voice. Song a musical tinkling, typically a series of 6 or 7 evenly spaced double syllables, "chilli-chilli-chilli-chilli-chilli, chur chee-chee-chee eh". Call a disyllabic "tscheddap" or "sheddap"; location call a thin high-pitched "see" or a soft "tic".
Habitat. Rocky semi-arid montane shrubland; found in scrub oak (*Quercus*), pinyon pine (*Pinus*), oak savanna, pinyon–juniper (*Pinus–Juniperus*), manzanita (*Arctostaphylos patula*), mesquite (*Prosopis*), mixed cacti (especially *Opuntia*), streambed shrubbery, and pine–oak forest. Sea-level to 1500 m.
Food and Feeding. Diet principally seeds; also takes small animal items, including insects, millipedes (Diplopoda), spiders (Araneae) and snails (Gastropoda), and fruit when available. Forages mainly on ground or low in vegetation. Searches on ground by using technique of two-footed scratch; hops or runs on ground.
Breeding. Season Mar to early Jul (rarely Sept); often double-brooded. Partners remain together all year and defend territory throughout year. Nest built by female, a bulky cup composed largely of dry grasses and plant stems, even flowers at times, lining of fine grasses, rootlets, hair or wool, generally placed 0·5–4 m above ground, often against main trunk of small tree such as mesquite, hackberry (*Celtis*), pinyon pine or juniper, or cholla cactus (*Opuntia*). Clutch 2–5 eggs, most commonly 3, ground colour ranging from white to pale blue and markings from blackish to dark brown or rusty, two patterns, one with dark and contrasting blotching and scrawls, other with finer and less dark speckles; incubation by female, both parents feed young at nest; no information on duration of incubation and nestling periods. Nests parasitized by Brown-headed (*Molothrus ater*) and Bronzed Cowbirds (*Molothrus aeneus*), but at low rates.
Movements. Sedentary; some slight elevational movements in winter.
Status and Conservation. Not globally threatened. Fairly common to locally common. Some local populations extirpated through development, especially along rivers in SW USA.
Bibliography. Armani (1985), Austin & Smith (1974), Beadle & Rising (2002), Davis (1951), Dawson (1954), Howell & Webb (1995), Hubbard & Crossin (1974), Johnson & Haight (1996), Marshall (1960), Marshall & Johnson (1968), Miller *et al.* (1957), Parkes (1957), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Russell & Monson (1998), Stahlecker (2002), Zink (1988), Zink & Dittmann (1991), Zink *et al.* (2001).

165. White-throated Towhee

Pyrgisoma albicolle

French: Tohi à gorge blanche **German**: Weißkehl-Grundammer **Spanish**: Toquí Oaxaqueño

Taxonomy. *Pipilo albicollis* P. L. Sclater, 1858, San Miguel de las Peras, Oaxaca, Mexico.
Formerly placed in genus *Pipilo* and sometimes in *Melozone*. Molecular analysis indicates that present species and *P. fuscum* are sister-taxa. Proposed race *parvirostre* (described from NC Oaxaca) was based on seasonal differences in plumage and bill length; synonymized with nominate. Two subspecies currently recognized.
Subspecies and Distribution.
P. a. marshalli (Parkes, 1974) – S Puebla (possibly also E Guerrero), in S Mexico.
P. a. albicolle (P. L. Sclater, 1858) – E Guerrero E to C Oaxaca, in S Mexico.



Descriptive notes. 18·5–22·5 cm; 42–50 g. Large, long-tailed sparrow. Has crown, nape, upperparts and tail brown; upperwing brown, two narrow pale wingbars, that of median coverts whiter and more contrasting; side of head brown, white supercilium from supraloral area to above eye, some whitish below eye, especially on submoustachial area, which becomes cinnamon on lower half, blackish malar stripe; chin and foreneck white contrasting with rusty-cinnamon throat, side of breast grey, becoming cinnamon on flanks and undertail-coverts, central abdomen whitish with grey mottling; iris reddish; upper mandible dusky brown, lower mandible paler; legs horn-coloured. Sexes similar in plumage. Juvenile is similar to adult, but with chest brownish-mottled, wingbars pale cinnamon. Race *marshalli* duller and greyer. Voice. Song a series of chipping notes with one or more introductory notes, "chik chik tchu-chu-chu-chu chi-i-ir". Call a slurred metallic "churenk".
Habitat. Broken semi-arid montane shrubland, also pine–oak (*Pinus–Quercus*) forest, at 1000–2800 m.
Food and Feeding. Diet probably seeds, augmented with insects and fruit when available. Forages principally on ground or low in vegetation. Often scratches on ground.
Breeding. Season Feb–May. Nest a bulky cup of dry grasses, lined with finer grasses, rootlets and hair, placed on or near ground, sometimes beneath thick bush. Clutch 4 eggs, pale blue to whitish-blue and spotted dark brown or reddish. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Balsas region and interior Oaxaca EBA. Little information available; common within its limited range.
Bibliography. Armani (1985), Davis (1951), Howell & Webb (1995), Marshall (1960), Miller *et al.* (1957), Parkes (1957, 1974b), Ridgway (1901), Zink (1988), Zink & Dittmann (1991).

166. California Towhee

Pyrgisoma crissale

French: Tohi de Californie **German**: Kaliforniengrundammer **Spanish**: Toquí Californiano
Other common names: Brown Towhee (when treated as conspecific with *P. fuscum*); Inyo California Towhee (*eremophilum*)

Taxonomy. *Fringilla crissalis* Vigors, 1839, no locality = Monterey, Monterey County, California, USA.
Formerly placed in genus *Pipilo* and sometimes in *Melozone*. Molecular analysis indicates that present species and *P. aberti* are sister-taxa. Previously treated as conspecific with *P. fuscum*. Geographical variation slight, and to some extent clinal; in California, *petulans* intergrades with nominate in Santa Cruz County and nominate intergrades with *senicula* in interior and SE, while specimens of *carolae* from C California show tendency towards *senicula*. Also, *bullatum*, *carolae* and *eremophilum* all similar to nominate and perhaps better subsumed in it; further, *bullatum* possibly not valid, purported characters being possibly due to comparison of reddish "foxed" specimens with newer "unfoxed" ones, and, similarly, *carolae* doubtfully valid and difficult to characterize. Proposed race *kernense* (described from Kelso valley, in Kern County, in California) is treated as a synonym of *carolae*. Eight subspecies tentatively recognized.
Subspecies and Distribution.
P. c. bullatum (Grinnell & Swarth, 1926) – SW Oregon S to extreme NC California, in W USA.
P. c. petulans (Grinnell & Swarth, 1926) – N California in coastal zone from Humboldt County S to Marin County.
P. c. crissale (Vigors, 1839) – C coastal California from N Monterey County E to W edge of San Joaquin Valley, S to W Kern County and Ventura County.
P. c. carolae (McGregor, 1899) – interior California from Humboldt County S to Napa County and E to foothills of Cascades and Sierra Nevada, S on E side of San Joaquin Valley to Kern County.
P. c. eremophilum (van Rossem, 1935) – Argus Mts, in Inyo County (California).
P. c. senicula (Anthony, 1895) – C coastal California (San Luis Obispo County), and San Joaquin Valley, S to extreme NW Mexico (NW Baja California).
P. c. aripolium (Oberholser, 1919) – C Baja California from 28°55' N S to Guajademi (26°35' N).
P. c. albigula (S. F. Baird, 1860) – S Baja California S from c. 26°35' S.

Descriptive notes. 21–24 cm; 46·3–61·2 g (male average 53·9 g, female average 51·8 g). Large, long-tailed, nearly uniformly brown sparrow. Nominate race has crown to hindneck and upperparts greyish-brown, crown often tinged richer brown, face rusty brown; upperwing dark grey-brown, darker than back, feathers narrowly edged paler, tail blackish-brown; throat rich buff, distinct gorget of darker streaks; underparts pale greyish-buff, paler on belly, lower flanks more buff, undertail-coverts rusty cinnamon; iris orang-ish-brown; bill horn-coloured, lower mandi-ble paler; legs pale brownish. Sexes similar in plumage. Juvenile is similar to adult, but somewhat duller in colour, greater and median upperwing-

coverts with pale buff tips (two wingbars), underparts faintly streaked dark. Races differ mainly in plumage tone: *bullatum* is supposedly more rufous than others, but this possibly due to "foxing" of specimens; *petulans* is medium greyish-brown, tinged with buffy; *carolae* is said to be similar to nominate, but darker above and a little paler on throat; *eremophilum* is said to be more greyish than nominate, but poorly differentiated; *senicula* has a rather small bill, and is darker and more richly coloured than nominate; *aripolium* is paler and longer-billed than previous; *albigula* is most distinctive and palest race, has obvious rufous crown patch, pale buff chin and throat, and whitish belly, grading to cinnamon-buff on undertail-coverts, some having dark chest spot (characteristic of *P. fuscum*). Voice. Song a series of staccato notes, accelerating in speed, "tss tss tss tsurr tsurr" or "chip chip chip chip chip"; male gives chatter-duet with female, "tss tss it tss, shi chi chi chi chi, shuchu shee, tsee tsee", on different pitches, first falling and then rising. Call a high-pitched "tsip" or "chip", or emphatic "chink"; location call a thin high-pitched "seep".

Habitat. Brushy hillsides, shrubby thickets, streamside thickets, chaparral, especially chamise (*Adenostoma fasciulatum*) and wedgeleaf ceanothus (*Ceanothus cuneatus*), also manzanita (*Arctostaphylos*), and dry upland chaparral; also dense thickets of willow (*Salix*) and desert olive (*Forestiera pubescens*) beside streams in Argus Mts (race *eremophilus*); commonly in parks and gardens having suitable cover. Away from coast, prefers dense vegetation of usually dry canyon bottoms, and desert slopes. Sea-level to c. 1500 m, less commonly to 2375 m.

Food and Feeding. Diet principally seeds; also small animal items, including insects, millipedes (Diplopoda), spiders (Araneae) and snails (Gastropoda), and fruit when available. Forages mostly on ground or low in vegetation. Searches on ground by using technique of two-footed scratch; hops or runs on ground.

Breeding. Season mid-Mar to end Jun; double-brooded. Maintains pair-bond and is territorial throughout year. Nest constructed by female, a loosely built open cup of dry grasses and twigs, lined with hair, seed down, horsehair and soft bark, generally placed 1–4 m up (rarely on ground) in densest part of shrub or small tree, usually supported by several branches; sometimes on artificial structure near house, and reported as nesting even inside hollowed hanging gourd. Clutch 2–5 eggs, most commonly 4; incubation by female, period usually 11 days, sometimes up to 14 days; chicks fed by both parents, nestling period 8–11 days. Frequent host of Brown-headed Cowbird (*Molothrus ater*); much productivity often much lowered, largely through clutch reduction.

Movements. Mainly resident. Some post-breeding upslope movements detected in some areas of California; similarly, downslope movements locally after major snowfalls.

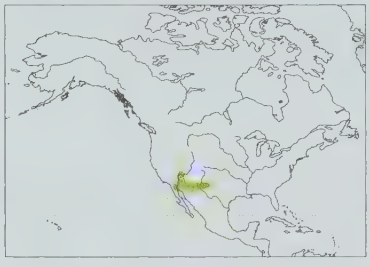
Status and Conservation. Not globally threatened. Race *eremophilus* designated as "Threatened" and protected under the Endangered Species Act in the USA since 1987. Otherwise, generally common to very common throughout most of range; a very common species of suburban backyards throughout California (USA). Common to fairly common in Baja California (Mexico). Appears to be generally insensitive to natural habitat loss, in part because it readily adapts to exotic vegetation. Race *eremophilus*, restricted to W & E slopes of S Argus Mts, in E California, is at risk from various factors; between 1992 and 1995 its population was believed relatively stable at c. 200 individuals; in comprehensive survey in 1998, 640 adults found (72% of these within the China Lake Naval Air Weapons Station), and survey in 2004 estimated range-wide population of 725 adults. Main threat to *eremophilus* was destruction of riparian habitat by cattle, feral horses and burros (donkeys), and off-road vehicles, as well as campers; since the towhee was placed on federal endangered-species list in 1987, these threats have been greatly reduced. In recent years fire has become a threat locally, but magnitude of impact not known. Removal of invasive exotic vegetation, e.g. salt cedar (*Tamarix*), also recommended for conservation purposes.

Bibliography. Beadle & Rising (2002), Benedict (2007), Byers, Curson & Olsson (1995), Davis (1951, 1957b), Dodge *et al.* (1995), Ellison (1999), Grinnell (1915), Gustafson *et al.* (1994), Howell & Webb (1995), Kunzmann *et al.* (2002), Laabs *et al.* (1995), Marshall (1960), Miller *et al.* (1957), Parkes (1957), Purcell & Verner (1998), Pyle (1997), Ridgway (1901), Rising & Beadle (1996), Zink & Dittmann (1991).

167. Abert's Towhee

Pyrgisoma aberti

French: Tohi d'Abert **German**: Schwarzkinn-Grundammer **Spanish**: Toquí de Abert



Taxonomy. *Pipilo aberti* S. F. Baird, 1852, "New Mexico" = vicinity of Gila Bend, Maricopa County, Arizona, USA.

Formerly placed in genus *Pipilo* and sometimes in *Melozone*. Molecular analysis indicates that present species and *P. crissale* are sister-taxa. Geographical variation clinal; species perhaps better treated as monotypic. Proposed race *voorhiesi* (described from c. 15 km S of Tucson, in Arizona) treated as synonym of *dumeticolus*. Two subspecies tentatively recognized.

Subspecies and Distribution.

P. a. dumeticolus (van Rossem, 1946) – SW USA from SW Utah S through Colorado Valley in SE Nevada to SE California, and E along Gila R in S Arizona, also extreme NW Mexico (extreme N Baja California and NW Sonora).

P. a. aberti (S. F. Baird, 1852) – SW USA in S Arizona and SW New Mexico.

Descriptive notes. 20–23 cm; 38·9–55·6 g. Large, long-tailed sparrow with relatively uniform appearance. Nominate race has lower forehead, lores and chin black, rest of head and upperparts buff-tinged greyish-brown, flight-feathers and tail dark brown with pale buff edges; below mostly pinkish-brown, undertail-coverts rusty cinnamon; iris mahogany-red; bill pale, brownish to greyish; legs grey to pale yellowish-flesh. Sexes similar in plumage. Juvenile is similar to adult, but somewhat duller in colour, with greater upperwing-coverts tipped cinnamon-brown, and thin streaks on flanks and belly. Race *dumeticolus* is very like nominate, but slightly greyer above and slightly darker below. Voice. Song a rather sharp series of notes, "peep peep chee-chee-chee", " sleep cleep cha cha cha" or "chi chi chi chur chur chur chz"; unmated male may sing throughout day; mated males sing little (song apparently little used in territorial defence), although male may give staccato "peep" at dawn to mark territorial boundaries. Mated partners may duet. Call a sharp "peep" or "huit huit", or loud "cut"; location call a loud "seep".

Habitat. Riparian cottonwood–willow (*Populus fremontii–Salix gooddingii*) woodlands with dense understorey, dense mesquite (*Prosopis*) thickets, exotic vegetation such as salt cedar (*Tamarix*), and quailbush (*Atriplex*) at edge of agricultural fields. Generally found along perennial watercourses.

Food and Feeding. Diet on lower Colorado R principally insects: in winter 73% of diet was insects, and in summer 96%. Beetles (Coleoptera) especially taken, but also ants (Formicidae), caterpillars (Lepidoptera), grasshoppers (Orthoptera) and cicadas (Cicadidae); seeds, especially those of Chenopodiaceae, also taken. Forages mostly on ground or low in vegetation. Searches on ground by using technique of two-footed scratch; hops or runs on ground.

Breeding. Season Mar–Sept; usually double-brooded. Pair-bond maintained retained throughout year. Nest built by female, taking c. 1 week, a bulky cup of twigs, dry leaves and bark strips, lined with materials such as soft inner bark of cottonwood species (*Populus*), hair and soft grasses, generally placed 1–4 m above ground (rarely on ground) in small tree or shrub such as Mexican elderberry (*Sambucus mexicanus*) or in mistletoe (*Phoradendron californicum*). Clutch 1–4 eggs, almost always 3, whitish, with dark brownish or blackish splotches around wide end; incubation by female, period 14 days; chicks fed by both parents, nestling period 12–13 days. Nests parasitized relatively frequently by Brown-headed Cowbird (*Molothrus ater*).

Movements. Sedentary.

Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Much of this species' preferred streamside habitat has been cleared and modified by humans, primarily for agricultural land, a process started before colonization by European settlers; habitat degraded also through overgrazing by cattle, construction of dams, channelization, and abstraction of water for drinking supplies and cattle-ranching. Although it has to some extent adapted to some urban habitats, and occupies exotic vegetation e.g. along ditches in S Arizona, as well as invasive salt cedar, these habitats are not optimal and do not compensate for habitat destroyed. Vulnerable also to brood parasitism by Brown-headed Cowbirds.

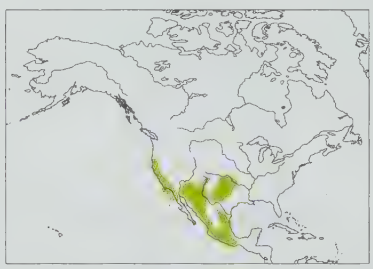
Genus *AIMOPHILA* Swainson, 1837

168. **Rufous-crowned Sparrow**

Aimophila ruficeps



French: Tohi à calotte fauve **German**: Rostscheitelammer **Spanish**: Chingolo Coronirrufo

Taxonomy. *Ammodromus ruficeps* Cassin, 1852, Calaveras River [east of Stockton], California, USA. Genus closely related to *Melozone* and *Pyrgisoma*. Geographical variation rather poorly marked. For convenience, races sometimes divided into "Pacific-coast group" (nominate, *canescens* and *obscura*), "SW-desert group" (*eremoeca* and *scottii*), and "Mexican group" (remaining races); most races in last group are very poorly differentiated. Race *eremoeca* intergrades with *scottii* in W Texas and with *pallidissima* in N Mexico (Coahuila), and last two may be synonyms of *eremoeca*; likewise, *boucardi* intergrades with *eremoeca* in E Mexico; in W Mexico *suttoni* intergrades with (and may be better subsumed in) *extima* and may intergrade also with *fusca*, and latter intergrades in SW Guanajuato with *simulans*, from which *rupicola* is possibly inseparable. Taxonomic review required. Eighteen subspecies currently recognized.

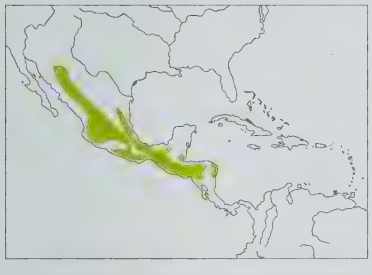
Subspecies and Distribution.

A. r. ruficeps (Cassin, 1852) – C California (coast ranges and W slopes of Sierra Nevada), in SW USA.
A. r. canescens Todd, 1922 – SW California and extreme NW Mexico (NW Baja California E to base of Sierra San Pedro Mártir, S to c. 30°30' N).
A. r. obscura Dickey & van Rossem, 1923 – islands of Santa Cruz, Anacapa and Santa Catalina, off SW California.
A. r. sanctorum van Rossem, 1947 – Todos Santos Is, off NW Baja California (NW Mexico).
A. r. scottii (Sennett, 1888) – SW USA (N & E Arizona and SW New Mexico) S to N Mexico (NE Sonora and NW Coahuila).
A. r. rupicola van Rossem, 1946 – mountains of SW Arizona.
A. r. eremoeca (N. C. Brown, 1882) – S USA from SE Colorado, SW Kansas and W & C Oklahoma S through E New Mexico and W Texas to N Mexico (N Chihuahua and C Coahuila).
A. r. sororia Ridgway, 1898 – extreme S Baja California, in W Mexico.
A. r. simulans van Rossem, 1934 – NW Mexico from SE Sonora and SW Chihuahua S to N Nayarit, SW Zacatecas, N Jalisco and W Guanajuato.
A. r. phillipsi Hubbard & Crossin, 1974 – SE Sinaloa (Palmito area).
A. r. suttoni Hubbard, 1975 – E Nayarit and N & W Jalisco, possibly also in Colima.
A. r. fusca (Nelson, 1897) – S Nayarit, SW Jalisco, N Colima and Michoacán.
A. r. extima A. R. Phillips, 1966 – E Jalisco and N Michoacán.
A. r. pallidissima A. R. Phillips, 1966 – NE Mexico from S Coahuila S to N San Luis Potosí and E to SE Tamaulipas.
A. r. boucardi (P. L. Sclater, 1867) – E Mexico from C Coahuila, C Nuevo León and S Tamaulipas S through San Luís Potosí to Distrito Federal, Tlaxcala, N Puebla and CW Veracruz.
A. r. duponti Hubbard, 1975 – Valley of Mexico.
A. r. australis (Nelson, 1897) – S Mexico (Guerrero, S Puebla and Oaxaca).
A. r. laybournae Hubbard, 1975 – WC Veracruz S to SE Puebla and NC Oaxaca.

Descriptive notes. 13·5–15 cm; 15·2–23·3 g. A medium-sized sparrow with large bill and long, rounded tail. Nominate race has crown rusty, thinly outlined with black above bill, sometimes with indistinct grey median crownstripe; grey supercilium becoming white above lores, narrow white eyering, blackish eyestripe becoming rusty behind eye, brownish-grey ear-coverts; pale buffish-white submoustachial stripe, thin black malar stripe; upperparts greyish with broad rusty streaks, rump unstreaked; upperwing and tail brown, wing feathers with pale edges, tertials with some rufous in edges, rectrices edged paler; throat whitish-buff, becoming greyer on breast and brownish-grey on rest of underparts, paler on belly and with buffy tinge on undertail-coverts; iris dark brown; bill dark grey, paler below; legs flesh-coloured. Sexes similar. Juvenile is like adult, but with indistinct grey streaks below. Races differ mainly in plumage tone and in size, nominate being small, with small bill, and relatively dark above: *canescens* is similar to nominate, but with longer tail, smaller bill, and slightly more greyish tone; *obscura* is similar to nominate, but larger, and darker and colder in tone, pale brownish below; *scottii* is larger than nominate, with medium-sized bill, greyish above, pale brown with grey tinge below; *eremoeca* is like previous in size, but with shorter tail and longer bill, upperparts more olive and less well streaked, greyer below; *sanctorum* is darkest of all, darker than *obscura*; *rupicola* is like *scottii*, but slightly darker and greyer above; *sororia* is palest of coastal Mexican races, paler than nominate; *simulans* is more rufous above and paler below than *scottii*, smaller-billed than preceding race; *suttoni* buffier above than previous, with dorsal streaking redder; *fusca* is darker and more extensively rufous above, has darker crown lacking grey median stripe; *phillipsi* is dark and rather brown; *pallidissima* is large, very grey and generally rather pale, darker crown contrasting with grey back, somewhat like *eremoeca*, but darker on crown, with more extensive dorsal streaking; *boucardi* is like previous, but darker and browner, with browner, often broader dorsal streaking; *duponti* is darkest and greyest race; *australis* is similar to *scottii*, but smaller, with shorter bill; *extima* greyer above than previous, with chestnut-brown crown, and broader dorsal streaking; *laybournae* is pale, with greyish upperparts and dusky streaking. Voice. Variable, but generally 6–9 jumbled or staccato "chip" notes, or "tchee-dle tchee-dle tchee-dle tchee-dle tchee-dle tchee-dle". Call a distinctive nasal "dear" or a series of "dear dear" notes; alarm call an upward-slurred "tzit".

Habitat. Dry hillsides and canyons with low cover of grass, forbs and bare ground. In California often found in California sage (*Artemisia californica*) on open grassy hillsides with scattered brush and rocks; in S California in moist coastal scrub. Elsewhere, found in chaparral, oak (*Quercus*) woodland, pine–oak (*Pinus–Quercus*) woodland, sometimes in pinyon–oak–juniper (*Pinus–Quercus–Juniperus*). In Texas also in dwarf oak in hilly country with scattered boulders. In Zacatacas (Mexico), has been found apparently breeding in mesquite–prickly pear (*Prosopis–Opuntia*) vegetation. Sea-level to low hills, occasionally to 1350 m.

Food and Feeding. Little information. In autumn and winter eats mostly seeds; some insects taken, also small lizards and berries. Forages on ground and low in bushes; gleans items. Difficult to observe. Usually in small groups outside breeding season.



Breeding. Breeds in late winter and spring (Feb–Jun) in California, but in summer (Jul–Sept) in SW deserts, and recorded in Jun and Jul in S Mexico (Oaxaca); nests after rain, nest-building beginning once appropriate humidity and grass conditions present. Monogamous; pair-bond maintained during winter. Nest built by female, a bulky cup made largely from dry grass, lining including finer

grass and animal hair, placed on ground and well hidden, often by overhanging grass, at base of bush, or on rocky slope; rarely up to 45 cm above ground in shrub. Clutch 2–5 eggs, usually 3 or 4, pale bluish-white or whitish and unmarked; incubation by female, period 11–13 days; chicks fed by both parents, nestling period 8–9 days. Rare host of Brown-headed Cowbird (*Molothrus ater*).
Movements. Essentially sedentary; some move downslope in winter, and some may make post-breeding shift upslope in California. Seldom found outside known range; few records of wandering individuals in coastal Texas, S & E Kansas and W Arkansas.
Status and Conservation. Not globally threatened. Often common or very common in appropriate habitat. In California insular race *obscura* listed as being "of Special Concern" owing partly to habitat changes caused by fire suppression.
Bibliography. Anon. (1998), Armani (1985), Binford (1989), Busy *et al.* (1999), Collins (1999), DaCosta *et al.* (2009), Ellison (1999), Fredrickson (1951), Hellmayr (1938), Howell & Webb (1995), Hubbard (1975), Hubbard & Crossin (1974), Janzen (2002), Miles (1986), Miller *et al.* (1957), Morrison & Bolger (2002a, 2002b), Morrison *et al.* (2004), Myers (1909), Pemberton (1910), Remsen & Cardiff (1979), Schram (2009), Shuford & Gardali (2008), Storer (1955), Wauer (1965, 1967), Willard (1912), Wolf (1977), Yuri & Mindell (2002).

169. **Rusty Sparrow**
Aimophila rufescens

French: Tohi roussâtre **German**: Rostrückenammer **Spanish**: Chingolo Rojizo
Other common names: Mexican Rusty Sparrow

Taxonomy. *Pipilo rufescens* Swainson, 1827, Temascaltepec, México, Mexico.
Genus closely related to *Melozone* and *Pyrgisoma*. Race *pyrgitoides* intergrades with *pectoralis* in area from S Mexico (C Chiapas), NC Guatemala and W Belize E to interior highlands of Honduras (possibly also of Nicaragua). In Mexico, proposed races *sinaloa* (described from S Sinaloa), *pallida* (from Etzatlán, in Jalisco), *disjuncta* (from San Gabriel Mixtepec, in S Oaxaca) and *cinerea* (from Cerro de la Gineta, in SW Chiapas) are all treated as synonyms of nominate, and *newmani* (from E of Ciudad del Maiz, in San Luis Potosí) is considered synonymous with *pyrgitoides*; *gigas* (from Nebaj, 80 km N of Quiche, in SW Guatemala) is synonymized with *pectoralis*. Seven subspecies recognized.
Subspecies and Distribution.
A. r. antonensis van Rossem, 1942 – Sierra de San Antonio, in NC Sonora, in NW Mexico.
A. r. mcleodii Brewster, 1888 – NW Mexico from E Sonora and W Chihuahua S to N Sinaloa and NW Durango.
A. r. rufescens (Swainson, 1827) – W & S Mexico from S Sinaloa S to Jalisco, Colima, Guerrero, S Oaxaca and SW Chiapas, and E to Guanajuato, México and S Puebla.
A. r. pyrgitoides (Lafresnaye, 1839) – E & SE Mexico from S Tamaulipas and E San Luis Potosí S through E Puebla and Veracruz to N Oaxaca and N & C Chiapas, and S to Honduras, N & C El Salvador and NW Nicaragua.
A. r. pectoralis Dickey & van Rossem, 1927 – S Mexico (Chiapas) and C & S Guatemala S to Honduras and El Salvador.
A. r. discolor Ridgway, 1888 – N Honduras and NE Nicaragua.
A. r. hypaethra Bangs, 1909 – Pacific slope of Guanacaste Cordillera, in NW Costa Rica.

Descriptive notes. 16·5–20 cm; 28·2–49·7 g. A large sparrow, larger in N than in S, with large bill and long, rounded tail. Nominate race has rusty crown with grey median stripe, often a thin black lateral line above supercilium, white supercilium becoming grey behind eye, broken white eyering, thin black eyestripe becoming dark chestnut behind eye; ear-coverts greyish, pale buff-grey to whitish submoustachial stripe, contrasting black malar stripe; upperparts rufous-brown with dark grey-brown streaks and spots, rump plainer rufous; upperwing and tail mostly rusty; throat whitish, underparts pale buffy brown to greyish-buff, deeper brown on flanks and paler on belly; iris dark brown; bill mostly blackish above, paler below; legs light brown to pinkish-flesh. Sexes similar. Juvenile has crown, nape and upperparts rufous-brown with dark brown to blackish streaks, broad buffy supercilium and submoustachial stripe, and underparts washed pale yellowish and streaked brown, lower mandible bluish-flesh. Race *mcleodii* is larger than nominate, also duller brown and less streaked, lacking pale median crownstripe and black line above supercilium; *antonensis* resembles previous, but paler and greyer; *pyrgitoides* is buffy above and has distinct dark streaks on back, also more buffish below than nominate; *pectoralis* is like nominate, but underparts greyish, and throat whiter, thus appearing to have breastband; *discolor* is smaller than nominate, greyish on side of head, rufous on upperparts and more richly coloured buff-brown on flanks; *hypaethra* is like nominate, but darker and more streaked above, with dusky lateral crownstripe. Voice. Song a varied, usually short series of clear chipping notes, e.g. "cheeu shik-chik". Call a fast dry chatter; also a scolding "chrrr-rrr-rrr".
Habitat. In Sonora and Chihuahua inhabits logged pine (*Pinus*) forests and pine–oak (*Pinus–Quercus*) woodlands with patches of *Ceanothus* and bracken (*Pteridium*) understorey; in Zacatecas found in bunch-grass beneath oaks; in Jalisco grassy hillsides dominated by open legume–oak vegetation. In lowlands of E Mexico (from S Tamaulipas) S to Honduras and Nicaragua occurs in pinelands with extensive grassland areas. From near sea-level to 2400 m.
Food and Feeding. Little information. Diet probably seeds, small insects, spiders (Araneae) and fruits; sometimes takes nectar. Forages principally on or near ground or low in vegetation. Often in pairs or small groups.
Breeding. Records mostly mid-May to Sept; nest with eggs on 7th Jun in Guatemala (at Volcán de Agua, 2000 m), and a female laying in Oct in El Salvador, where breeding season may be Jul–Nov; perhaps little synchrony among pairs. Probably monogamous. Nest a well-woven structure of grass, lined with finer fibres, well hidden on ground or up to 2·4 m above it in vegetation; of eight nests found in Morelos (E of Cuarnavaca, above 1800 m), in Mexico, during May to early Jul, five were placed on ground. Clutch commonly 2–3 eggs, sometimes 4, whitish-blue with dark spotting. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common to common throughout range. Often common or very common in optimum habitat.
Bibliography. Anon. (1998), Armani (1985), Binford (1989), DaCosta *et al.* (2009), Dickey & van Rossem (1938), Griscom (1932), Hellmayr (1938), Howell & Webb (1995), Marshall (1957), Miller *et al.* (1957), Rowley (1962), Storer (1955), Wolf (1977).

170. **Oaxaca Sparrow**
Aimophila notosticta

French: Tohi d'Oaxaca **German**: Oaxacaammer **Spanish**: Chingolo Oaxaqueño

Taxonomy. *Peucaea notosticta* P. L. Sclater and Salvin, 1868, central Mexico, probably Puebla.
Genus closely related to *Melozone* and *Pyrgisoma*. Monotypic.
Distribution. NW & C Oaxaca (E to Santiago Matatlán) and probably adjacent SE Puebla, in S Mexico.

Descriptive notes. 15–16·5 cm; 26·4–30 g. A medium-sized sparrow with large bill and rounded tail. Has crown chestnut, grey median stripe above bill, narrow black edging above supercilium; lores black, supercilium white above lores, becoming greyer posteriorly, narrow white eyering, brown postocular stripe; ear-coverts grey, light buffish-white submoustachial stripe, contrasting black malar stripe; upperparts warm brown, mantle, scapulars and back with narrowly rusty-edged black streaks; upperwing dark brown, most feathers edged greyish-buff, inner secondaries and tertials more broadly edged rufous; tail dark grey-brown, feathers narrowly edged paler; throat whitish; side of neck and breast grey, becoming buff-grey on flanks and belly, and paler ochre-brown on undertail-coverts; iris dark brown; bill black, sometimes pale grey below; legs dull flesh-coloured. Sexes similar. Juvenile is duller and more buffish than adult, crown and nape finely streaked black, upperparts narrowly but heavily streaked dark brown, lower throat to breast and flanks washed pale yellowish and narrowly streaked dark brown, bill paler. Voice. Song a single note, sometimes 2, followed by varied chipping notes, e.g. "swi, chi-chi-chi-chi-chi-chi". Call a dry chatter, or high-pitched "tik"; also gives nasal scolding chatter like that of a wren (Troglodytidae), e.g. "shashashasha..." or "chehchehcheh", also a protracted, harsher chatter.
Habitat. Arid montane scrub with scattered oaks (*Quercus*) and manzanita (*Arctostaphylos*), and thorn-scrub; at 1500–1900 m.
Food and Feeding. Little information. Diet probably seeds, small insects, spiders (Araneae) and fruits. Forages principally on or near ground or low in vegetation. May be seen in small flocks in winter.
Breeding. Breeding records in May, Jun and Jul. Probably monogamous. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Rare to locally fairly common within its limited range; habitat being destroyed by farming activities. Has moderately small range, within which estimated population fewer than 50,000 individuals; range probably decreasing owing to loss and degradation of habitat. Although significant areas of suitable habitat remain, these are under pressure from cutting for timber and firewood-gathering, and face threat of clearance for cattle-ranching; nevertheless, apparently no direct evidence of population decline. Recommended actions include the undertaking of surveys to determine the species' population size, and monitoring of trends through regular surveys; also, monitoring of rates of habitat loss and degradation within its range, and protection of suitable habitat.
Bibliography. Anon. (1998, 2010c), Armani (1985), Binford (1989), Butchart & Stattersfield (2004), DaCosta *et al.* (2009), Hardy (1980), Hellmayr (1938), Howell & Webb (1995), Miller *et al.* (1957), Stattersfield & Capper (2000), Storer (1955), Wolf (1977).

Genus *TORREORNIS* Barbour & J. L. Peters, 1927

171. **Zapata Sparrow**
Torreornis inexpectata

French: Bruant de Zapata **German**: Zapataammer **Spanish**: Chingolo de la Ciénaga
Other common names: Cuban Sparrow

Taxonomy. *Torreornis inexpectata* Barbour and J. L. Peters, 1927, Santo Tomás, Zapata Peninsula, Cuba.
Relationships of this species unclear; thought to be close to *Aimophila* or possibly to *Peucaea* (latter previously subsumed in *Aimophila*) because of general structure and skeletal data, but differs clearly in plumage. Three subspecies recognized.
Subspecies and Distribution.
T. i. inexpectata Barbour & J. L. Peters, 1927 – Zapata Swamp, in W Cuba.
T. i. varonai Regalado Ruiz, 1981 – Cayo Coco, off NC Cuba.
T. i. sigmani Spence & B. L. Smith, 1961 – coastal regions of province of Guantánamo, in SE Cuba.
Descriptive notes. 16·5 cm; 19·7–29·3 g. A large-headed, moderately long-tailed sparrow with medium-sized conical bill and short, rounded wings. Nominate race has chestnut crown with indistinct grey median crownstripe, grey supercilium becoming paler and whitish in supraloral area; face grey, narrow brown eyestripe, narrow dusky moustachial stripe from bill continuing around lower edge of ear-coverts, contrasting white submoustachial stripe bordered below by dark malar stripe, malar broadening towards breast; nape grey, upperparts contrastingly olive, mantle to upper back and scapulars streaked brown; tail dark brown, feathers narrowly edged grey-buff; upperwing brownish, edges of median and greater coverts warmer brown, tertials edged rusty brown (creating

On following page: 172. Striped Sparrow (*Oriturus superciliosus*).

warm brown panel on folded wing); throat clean white; upper breast greyish, side of breast olive-yellow, lower breast and belly dull yellow, flanks more olive-yellow; iris dark chestnut; bill black, often with blue-grey on lower mandible; legs dull flesh-coloured. Sexes similar. Juvenile is similar to adult, but duller and more muted in coloration. Race *varonai* is like nominate, but crown darker rufous, bolder face pattern; *sigmani* is smaller, with relatively small bill, also paler, crown less intensely rufous, little greyish-olive on chest and flanks, yellow below paler and more extensive, and dorsally less noticeably streaked. Voice. Songs tend to be duets, initiated by male. Typical duet a highly synchronized series of high-pitched buzzes which become louder as song progresses, and slow and decrease in amplitude and frequency as they end in a chatter, "tzi-tzi-tzi...tiiitziii...tik-tik-thk"; total duration from less than 2 seconds to nearly 5 seconds. Another common type is the chatter-duet, with song comprised not of buzzes, but of shorter chatter notes given by both pair-members; another duet exists in which male sings buzz notes and female chatter notes. Songs of nominate race and *sigmani* are not significantly different. Contact call a buzz centred at 8 kHz, "zeea", female a single buzz, male often 2–4 in a series, buzz call of nominate race lower-pitched than that of *sigmani*; other calls include high thin "chip" and softer "pit" and a metallic "oing".

Habitat. Seasonally flooded sawgrass prairies in Zapata Swamp (nominate race); dry to semi-wet open forest in Cayo Coco (*varonai*); and coastal thorn-scrub, dry forest and cactus stands in Guantánamo (*sigmani*).

Food and Feeding. In Zapata Swamp feeds on eggs of apple snails (*Pomacea*) during wet season, and may take small lizards (*Anolis*); in dry season shifts to seeds and invertebrates. In Cayo Coco takes insects, as well as seeds and fruits found on ground. Guantánamo population known to eat cactus fruit (*Opuntia*), as well as seeds of coastal incense (*Tournefortia gnaphalodes*). Forages on ground, in manner of *Zonotrichia*, scratching in leaf litter with both feet together. In Cayo Coco can be observed while foraging in open trails, as well as on open ground within forest; in Zapata it keeps to dense grass and is difficult to see. Generally in twos or threes; occasionally in larger flocks.

Breeding. Season Mar–Jun. Appears to be territorial throughout year. Few nests known, all from the Zapata region, a grassy well-formed cup placed in grass tussock, surrounded by sawgrass; clutch 2 eggs, pale green with brown spots. No other information.

Movements. Sedentary.

Status and Conservation. ENDANGERED. Restricted-range species: present in Cuba EBA. Has small range, within which estimated total population 1000–2499 mature individuals, and thought to be decreasing. Three distinct populations: nominate race occupies small area of Zapata Swamp and numbers more than 250 individuals; *varonai* considered numerous within its very restricted range on Cayo Coco, in Camagüey Archipelago; and *sigmani* is restricted to small section of coast in S Guantánamo, where population perhaps 600–700 individuals (until recently, range of *sigmani* thought to be even smaller and population only 110–200 individuals). Although no new information on trends, this species is believed to be declining at slow rate owing to habitat loss and degradation; population of nominate race, however, apparently stable. Drainage and dry-season burning have adverse effects on habitat in Zapata Swamp; Cayo Coco is being further developed for tourism; and habitat on Guantánamo coast threatened by burning and subsequent colonization by grasses, followed by fencing for sheep-rearing. Although none of the three races is officially protected, each has been recorded in a protected area.

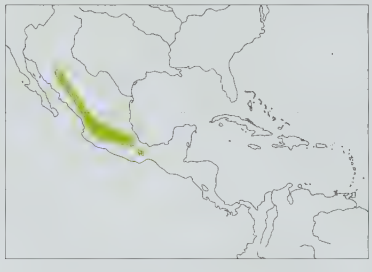
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Garrido & Kirkconnell (2000), González Alonso, González Bermudez & Quesada (1986), González Alonso, de las Pozas & González Bermudez (1982), Morton & González Alonso (1982), Raffaele *et al.* (1998), Spence & Smith (1961), Stattersfield & Capper (2000), Webster & Webster (1999).

Genus *ORITURUS* Bonaparte, 1850

172. Striped Sparrow

Oriturus superciliosus

French: Bruant rayé **German**: Streifenammer **Spanish**: Chingolo Rayado



Taxonomy. *Aimophila superciliosa* Swainson, 1838, Mexico.

Relationships of this species unclear; generally placed close to *Aimophila*, but molecular studies suggest that it is part of a group that also contains *Melospiza*, *Passerculus*, *Xenospiza*, *Pooecetes*, and *Ammodramus henslowi* and *Ammodramus bairdii*. Races poorly differentiated; specimens from Nayarit, Jalisco, Zacatecas, Aguascalientes and Michoacán reported as being intermediate. Two subspecies recognized.

Subspecies and Distribution.

O. s. palliatus (van Rossem, 1938) – W Mexico in Sierra Madre Occidental from E Sonora and SW Chihuahua S through E Sinaloa and W Durango to Nayarit and W Zacatecas.

O. s. superciliosus (Swainson, 1838) – S part of C plateau of Mexico in Jalisco, Aguascalientes and Guanajuato E to Tlaxcala and WC Veracruz, S to Michoacán, Morelos, Puebla and C Oaxaca.

Descriptive notes. 16·5–18 cm; 36·9–53·7 g. A large, flat-headed sparrow with long, rounded tail. Nominate race has crown rusty, thinly streaked with black, and with a more or less distinct pale buffy median crownstripe; long broad supercilium creamy white, side of face black; nape grey, streaked with black; upperparts buffish-brown, heavily streaked black (black feather centres), streaks heaviest on mantle (which also washed rufous); tail brown, feathers edged buffy brown; upperwing blackish, median and greater coverts with broad light buffish edges and whitish tips (forming two indistinct wingbars), primaries narrowly edged light greyish, secondaries thinly edged buffish-brown, tertials edged buff-brown and tipped white; throat white, underparts greyish-white, belly paler, flanks and undertail-coverts washed buffish; iris dark brown; bill black; legs pinkish. Sexes alike in coloration. Juvenile is similar to adult, but greyer, with lower throat, breast, belly and flanks thinly streaked with black. Race *palliatus* is paler overall and warmer brown above than nominate, but more greyish below, with whiter belly. Voice. Song 1–3 nasal chipping notes followed by rattling trill, "tiuk tiuk tiuk beeh beeh drrrrrrrrrr". Call a sharp "tik".

Habitat. Found in bunch-grass and probably other scrubby and grassy openings in or near humid pine–oak (*Pinus–Quercus*) forest, and in wet meadows. At 1500–3500 m.

Food and Feeding. Little information. Recorded as eating seeds and insects; adults seen to feed green plant material and insects to fledged young. Forages principally on or near ground and low in vegetation.

Breeding. Season May–Sept. Seemingly monogamous; may be loosely colonial. Nest a cup of dry grasses, lined with finer vegetation and sometimes hair, placed close to ground, often in thick bush. Clutch 3–4 eggs, white with greyish or brownish markings; incubation by female, period 13–14 days; no information on nestling period.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Locally common to fairly common. Suitable habitat for this species often destroyed by agricultural activities.

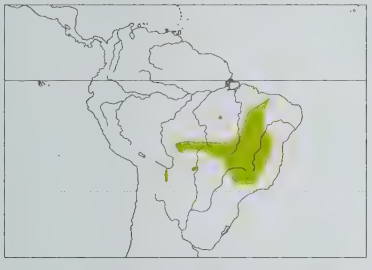
Genus *PORPHYROSPIZA*



P. L. Sclater & Salvin, 1873

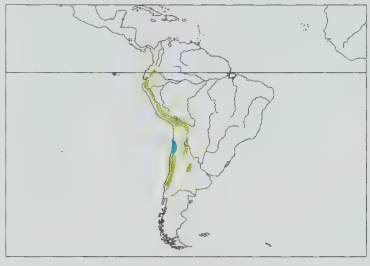
173. **Blue Finch**

Porphyrospiza caerulescens

French: Porphyrin à bec jaune **German**: Kobaltämmerling **Spanish**: Yal Azul
Other common names: Yellow-billed Blue Finch

Taxonomy. *Tanagra caerulescens* Wied, 1830, interior of Bahia, Brazil.
Often placed in family Cardinalidae because of resemblance to *Passerina*, and has sometimes been included in that genus. Molecular data suggest that its closest relative may be *Phrygilus alaudinus* and that both belong with the tanagers (Thraupidae); these two species are united by structure, bill shape, some aspects of coloration, and song, and both should probably be shifted to a new genus, for which the name *Corydospiza* is available (and which has priority over present genus). Monotypic.
Distribution. C & E Brazil from S Mato Grosso, SE Pará and C Maranhão S to Goiás, Piauí, W Bahia and W & C Minas Gerais, and E & S Bolivia (E Beni and SE Santa Cruz, probably also Chuquisaca).

Descriptive notes. 12·5 cm; 13 g. A slim finch with relatively long tail, and long bill with only slightly curved culmen. Male is bright indigo-blue throughout, becoming blackish on lores; wing and tail blackish, widely edged blue, centres of tertials broadly black; when freshly moulted, upperpart feathers tipped rufous (tips wear off by breeding season); iris dark brown; bill yellow, contrasting strongly with blue of head and body; legs dull pink. Female has head pale brownish with pale eye-crescents and slightly paler supercilium, upperparts warm brown, thinly streaked on back, with rump and uppertail-coverts greyish; wing and tail dark greyish, flight-feathers edged warm brown, upperwing-coverts warm brown with slightly paler tips (creating very narrow and poorly defined wingbars); buffy white below, narrowly streaked darker on throat, breast and flanks and more heavily streaked on undertail-coverts; bare parts similar to those of male, but bill duller yellow and with dark culmen and tip. Juvenile is like female, but richer brown, and more coarsely and densely streaked on breast and flanks. Voice. Sibilant 3-note song a repetitive "swee-sweeet-zhweew, swee-sweeet-zhweew, ...". Male gives a trill when close to nest.
Habitat. Open savanna and *cerrado*, and associated strongly with grassland. In particular a specialist of *campo rupestre* habitat, of rocky grassland interspersed with bushes and short trees; *campo rupestre* is often at higher elevations, on top of plateaux, and therefore patchy, occurring as islands in lower-elevation *cerrado* habitats.
Food and Feeding. Feeds on invertebrates and seeds. Gizzard samples contained 80% dry seeds (45 seeds of grasses and two unidentified) and 20% arthropods, latter comprising twelve Lepidoptera larvae, five beetles (Coleoptera), one ant (Formicidae) and one spider (Araneae). Adults provisioning a nest brought in caterpillars, walking-sticks (Phasmatodea) and grasshoppers (Orthoptera). Forages on ground. Generally singly and in pairs; in non-breeding season may form small foraging flocks.
Breeding. Very little information. Males begin to sing at end of dry season and beginning of wet season, suggesting breeding mainly or strictly at start of rainy season; nests (with eggs) found in Sept and another (with nestlings) in Nov. One nest made from dry grasses, placed low down, near ground, in a canelas-de-ema (*Vellozia squamata*) plant; another was constructed from grasses, and placed low down in grassy area. Clutch 2–3 eggs, white with sparse small brown and rusty speckles, these denser near wide end; incubation period 14 days; male helps female in feeding chicks, each parent roughly feeding young about twice per hour, no information on duration of nestling period.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to rare, and patchily distributed. Now rare and local in many formerly occupied areas in Brazil, and likely declining moderately rapidly owing to habitat loss; populations in E Bolivia appear to be faring better and are under less pressure. Main threats include conversion of *cerrado* to agriculture, especially for eucalypt (*Eucalyptus*) plantations, soybeans and exportable crops, and for pasture; by mid-1990s two-thirds of *cerrado* habitat had been extensively or significantly modified, most of this having occurred since middle of 20th century, and habitat losses continue. Occurs in several protected areas in Brazil, including Chapada dos Guimarães, Chapada dos Veadeiros, Serra do Cipó and Serra da Canastra National Parks; present in Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Anon. (2010c), Buzzetti & Silva (2005), Klicka *et al.* (2007), Lima & Buzzetti (2006), Maillard & Catari (2004), Parker & Rocha (1991), Ridgely & Tudor (1989), da Silva & Bates (2002), Stattersfield & Capper (2000).



Genus *PHRYGILUS* Cabanis, 1844

174. **Band-tailed Sierra-finch**

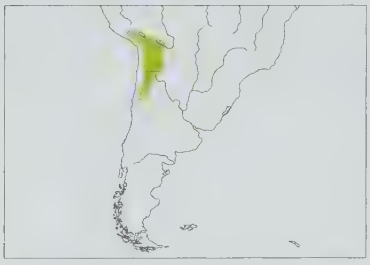
Phrygilus alaudinus

French: Phrygile à queue barrée **German**: Schwanzfleckenämmerling **Spanish**: Yal Platero

Taxonomy. *Fringilla alaudina* Kittlitz, 1833, Valparaíso, Chile.
Molecular data suggest that this species' closest relative may be *Porphyrospiza caerulescens* and that both belong with the tanagers (Thraupidae); these two species are united by structure, bill shape, some aspects of coloration, and song, and both should probably be shifted to a new genus, for which the name *Corydospiza* is available (and has priority over *Porphyrospiza*). Races form two groups, a N group of smaller and darker races (*humboldti*, *bipartitus*, *bracki* and *excelsus*) and S group of two larger and paler ones (nominate and *venturii*). Six subspecies recognized.
Subspecies and Distribution.
P. a. humboldti Koepcke, 1963 – SW Ecuador and NW Peru.
P. a. bipartitus J. T. Zimmer, 1924 – highlands of Ecuador S through coastal slope in Peru to extreme N Chile (Putre, in Arica–Parinacota region).
P. a. bracki O'Neill & T. A. Parker, 1997 – Huallaga Valley, in C Peru.
P. a. excelsus Berlepsch, 1906 – S Peru (highlands of Arequipa and Puno) and W Bolivia.
P. a. venturii E. J. O. Hartert, 1909 – NW Argentina Jujuy S to Catamarca; also Córdoba and San Luis).
P. a. alaudinus (Kittlitz, 1833) – C Chile from Antofagasta S to region of Los Ríos.

Descriptive notes. 13·5–14·5 cm; 17–30 g. A medium-sized, slim-shaped sierra-finch with long pointed bill and relatively long tail. Male nominate race has head to breast grey, slightly darker on lores, crown narrowly streaked; upperparts lead-grey with wide blackish streaks, rump plain grey; upperwing blackish with grey feather edging, and grey shoulder; tail blackish, bold white band midway on each feather except central pair (in flight, white band very obvious on underside); grey breast, whitish belly and vent, flanks with buffy-grey tinge; iris dark brown; bill and legs bright orange-yellow. Female is brown and strongly streaked on face, crown and entire upperparts; whitish-buff throat and breast, streaked on lower throat and breast, giving way to off-white belly and vent, flanks buff and streaked darker; wings brownish, edged buffy, tertials edged cinnamon; tail as on male, but white band slightly less extensive; bill and legs yellowish, duller than on male. Juvenile resembles female, but young male has grey wash on breast and reduced streaking on breast and flanks. Race *venturii* is like nominate, but larger and slightly darker; *excelsus* is smaller than nominate, darker above and with darker breast; *bipartitus* is darker grey on breast than previous, approaching blackish on chin, and dark colour of breast is sharply demarcated from white belly; *bracki* is smaller than last two, but has relatively long bill and legs, also has richer brown markings above (when fresh) and is paler grey, abdomen more extensively whitish; *humboldti* is small like previous, and pale, but lacks rich coloration of fresh upperparts. Voice. Song, from top of bush or rock, sometimes in flight, geographically variable. In Chile, a 2-note buzzy sneeze, "tzii-chew", repeated in a series three or more times; on coastal slope of Peru song similar, although often repeated in series of two; in Bolivia song simpler, more musical and less buzzy, "twee-twew", and given singly or in multiples of up to four.
Habitat. In C Chile, open grassy slopes, often with exposed rocks and moderate shrub growth; in coastal Peru, open, flat, sandy and sparsely covered areas with isolated shrubs in highland areas, and Lomas vegetation. Coastal semi-desert in SW Ecuador and NW Peru (race *humboldti*). Sea-level to 4000 m, usually below 2500 m.
Food and Feeding. Seeds and invertebrates; studies in winter months in C Chile determined that diet consisted entirely of seeds. On basis of diversity of food items in stomachs, niche breadth of this species appears to be much narrower than that of *P. fruticeti* and *P. gayi*, suggesting that it is much more of a food specialist. Forages on ground. Generally in pairs or family groups; forms mixed flocks with *P. fruticeti* during winter in C Chile.
Breeding. Season Sept–Feb (egg dates Sept–Nov) in C Chile; fledglings observed late May in S Peru (Puno), Jun in Bolivia (La Paz) and Mar in Argentina (Tucumán); flight display in Lomas region of coastal Peru in Sept–Nov, presumably breeding in that period. In aerial display, rises to 20 m above ground and sings during descent. Nest made from grass, placed on ground at base of thicker grass tussock. Clutch 3–5 eggs, pale pinkish-white to pale greenish with blackish and purplish spotting, this denser at wide pole. No other information.
Movements. Sedentary in most of range. In Chile, nominate race at least partially migratory, e.g. a breeding visitor through Las Chinchillas National Reserve (in Region IV), leaving the area during winter months; some breeding areas in Chile are under snow in winter, and downslope migration appears to occur; records in austral winter from as far N in Chile as Paposo (Antofagasta), where no breeding records, indicating general distributional shift to N during non-breeding season.
Status and Conservation. Not globally threatened. Locally common to uncommon throughout its large range. Occurs in few protected sites, perhaps one of the largest being La Campana National Park, in C Chile. No known threats.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Housse (1945), Jaksic (1997), Jaksic & Lazo (1999), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), O'Neill & Parker (1997), de la Peña (1987), Ridgely & Tudor (1989), Skinner (1935), Wetmore (1926), Zimmer (1924).

175. **Black-hooded Sierra-finch**



Phrygilus atriceps

French: Phrygile à tête noire **German**: Kapuzenämmerling **Spanish**: Yal Cabecinegro
Other common names: Northern Hooded Sierra-finch

Taxonomy. *Emberiza atriceps* d'Orbigny and Lafresnaye, 1837, "Tacora" (= Tarapacá), Chile (formerly in Peru).
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species may form a superspecies with *P. punensis*, *P. gayi* and *P. patagonicus* (the "hooded" group), and molecular data suggest that this group may be closely related to *Sicalis*. Has been considered conspecific with *P. gayi*, but the two rarely hybridize in area of NC Chile (between Atacama and Coquimbo) where they are sympatric (only one hybrid specimen known, from Guatín, in Antofagasta). Geographical variation minimal; individuals from C Bolivia S to NW Argentina slightly longer-billed than others, but difference likely clinal variation, also males from NW Bolivian Altiplano (Sajama) said to be particularly black-winged. Treated as monotypic.

On following pages: 176. Peruvian Sierra-finch (*Phrygilus punensis*); 177. Grey-hooded Sierra-finch (*Phrygilus gayi*); 178. Patagonian Sierra-finch (*Phrygilus patagonicus*); 179. Mourning Sierra-finch (*Phrygilus fruticeti*); 180. Carbonated Sierra-finch (*Phrygilus carbonarius*); 181. Plumbeous Sierra-finch (*Phrygilus unicolor*); 182. Ash-breasted Sierra-finch (*Phrygilus plebejus*); 183. Red-backed Sierra-finch (*Phrygilus dorsalis*); 184. White-throated Sierra-finch (*Phrygilus erythronotus*).

Distribution. S Peru (highlands of Arequipa, Moquegua and Tacna) S through highlands of SW Bolivia to N Chile (from highlands of E Arica–Parinacota S to Baños de Toro, in N Coquimbo) and NW Argentina (S to Catamarca).

Descriptive notes. 15·5–16 cm; average 24·3 g. A well-proportioned sierra-finch with relatively pointed bill. Male has solid black hood, contrasting strongly with russet upperparts and yellowish-russet underparts; wings and tail blue-grey, blackish with narrow pale edges on primaries and central tail feathers; underparts purest yellow on lower breast and belly, darker and more russet on breast, with vent and undertail-coverts white; iris chestnut; bill grey to black, often paler grey on lower mandible; legs greyish or blackish. Female is similar to male, but duller, with greyish cast to hood, and less intense coloration on body, but still with obvious russet tone; could be mistaken for male *P. punensis*, but hood blackish-grey (rather than blue-grey) and back warmer in tone. Juvenile is still duller than female, retains hooded pattern though throat whitish and streaked down to breast, body plumage more olive above, lacking yellower rump, and duller peachy yellow below, wings brownish with cinnamon wingbars; lacks marked supercilium and dark malar stripe of otherwise similar juvenile of *P. punensis*. Voice. Song a musical but repetitive series of notes given in alternating pairs, "tweep-tseep, tweep-tseep, tweep-tseep, tweep-tseep", or slightly more complex with one note doubled and then third given and this pattern then repeated; tends to sing more slowly, with notes shorter and more strident, than other members of "hooded group", which otherwise similar. Call a high-pitched and thin "ziip".

Habitat. Open highland scrub and shrubby areas, even where cacti dominant, also areas adjacent to grassy sites or *bofedal* areas (natural wetlands with spongy vegetation, or "cushion bogs"), also open *Polylepis* forests and edge; prefers some slope, not flat sites. Commonly found in highland villages, where it adapts well and becomes commensal and very tame. At 2400–4000 m.

Food and Feeding. Seeds and invertebrates. In highland villages will also take food scraps discarded by humans. Forages on ground. Generally in pairs, often with species of *Sicalis*, or with *P. unicolor* or *P. plebejus*. Exhibits less tendency to flock in non-breeding season than do *P. gayi* and *P. patagonicus*.

Breeding. Season mainly Nov–Jan, but nesting can occur at any time in year. Nest a grass cup, sometimes lined with camelid wool, placed in grass tussock, in bush, or even in hole in cliff or in man-made structure (30 cm deep) such as eaves of adobe house, or rock wall. Clutch 3–4 eggs, pale blue with fine brown spots, these concentrated at larger pole. No other information.

Movements. Sedentary.

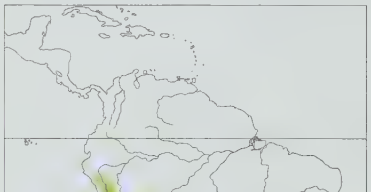
Status and Conservation. Not globally threatened. Common throughout its range. Benefits from its ability to live alongside humans. Occurs in several protected areas, including Reserva Nacional de Fauna Andina Eduardo Avaroa (Bolivia), Lauca and Volcán Isluga National Parks and Las Vicuñas National Reserve (Chile), and Los Cardones National Park and Pozuelos National Reserve (Argentina).

Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hellmayr (1932), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Marín *et al.* (1989), McCarthy (2006), Ridgely & Tudor (1989), Rocha & Quiroga (1996), Schulenberg *et al.* (2007).

176. Peruvian Sierra-finch

Phrygilus punensis

French: Phrygile du Pérou **German**: Punaämmerling **Spanish**: Yal Peruano
Other common names: Peruvian Hooded Sierra-finch



Taxonomy. *Phrygilus punensis* Ridgway, 1887, Lake Titicaca basin, Peru and Bolivia.

Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species may form a superspecies with *P. atriceps*, *P. gayi* and *P. patagonicus* (the "hooded" group), and molecular data suggest that this group may be closely related to *Sicalis*. Sometimes considered conspecific with *P. gayi*, which it resembles in appearance, but may be more closely related to *P. atriceps*. Two subspecies recognized.

Subspecies and Distribution.

P. p. chloronotus Berlepsch & Stolzmann, 1896 – N & C Peru (from Cajamarca S to Cuzco).

P. p. punensis Ridgway, 1887 – S Peru (Puno) and NW Bolivia (La Paz).

Descriptive notes. 15·5–16 cm; 35·9–38·5 g. Male nominate race has grey hood extending down to upper chest, lores blackish; upperparts dull russet with olive tone, tail feathers blackish with bold blue-grey edging; upperwing-coverts blue-grey and flight-feathers broadly edged blue-grey (making wing appear largely blue-grey); breast and flanks bright russet, belly more yellowish, vent and undertail-coverts white; iris dark brown; bill pinkish-grey, dark culmen and tip; legs dull pinkish. Female is similar in pattern to male, but hood paler in coloration, body plumage duller, more greenish above, and colour tones below more muted. Juvenile is streaked throughout, with slightly hooded appearance, has pale buff supercilium, and buffy throat bordered by wide brownish lateral stripes (which disrupt the generally hooded look), upperparts dull olive with obscure darker streaking, wings brownish with crisp buffy edgings (creating two narrow wingbars), tail brownish, underparts dull russet, becoming more yellowish on belly, off-white to pale buff on vent and undertail-coverts, most densely streaked on breast, more loosely on belly and flanks, and streaked brown on undertail-coverts. Race *chloronotus* is paler-headed and greener on upperparts and underparts than nominate. Voice. Song a musical but repetitive series of notes given in alternating pairs, "tweep-tseep, tweep-tseep, tweep-tseep, tweep-tseep"; has a more musical quality, and perhaps is generally lower-pitched, than song of *P. atriceps*. Call a high-pitched and thin "ziip".

Habitat. Shrubby and rocky highland slopes, also edge of villages in agricultural zones where ample shrub cover retained; also edge of *Polylepis* woodland. Both slope and shrub cover important. Usually not found in open grassy Altiplano plains. At 2500–4800 m.

Food and Feeding. Seeds and arthropods. Forages on ground. Generally singly or in pairs; in small foraging flocks in non-breeding season, and may form mixed flocks with various yellow-finches (*Sicalis*), other members of genus such as *P. unicolor*, or *Catamenia analis*.

Breeding. Breeds Jan–Jun. No other information available.

Movements. May descend to lower elevations in dry season.

Status and Conservation. Not globally threatened. Common to fairly common throughout its range. No known threats.

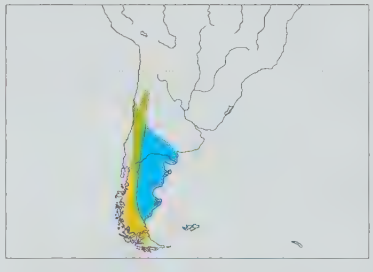
Bibliography. Armani (1985), Estrada & Rondan (2009), Fjeldså & Krabbe (1990), Hellmayr (1932), Johnson & Goodall (1967), Klicka *et al.* (2007), McCarthy (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

177. Grey-hooded Sierra-finch

Phrygilus gayi

French: Phrygile à tête grise **German**: Kordillerenämmerling **Spanish**: Yal Cabecigrís
Other common names: Southern Hooded Sierra-finch

Taxonomy. *Fringilla gayi* Gervais, 1834, Chile.



Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species may form a superspecies with *P. atriceps*, *P. punensis* and *P. patagonicus* (the "hooded" group), and molecular data suggest that this group may be closely related to *Sicalis*. Has been considered conspecific with *P. atriceps*, but the two rarely hybridize in area of NC Chile (between Atacama and Coquimbo) where they are sympatric (only one hybrid specimen known, from Guatín, in Antofagasta); sometimes thought conspecific with *P. punensis*, which it resembles in appearance. Range overlaps with that of *P. patagonicus* in various sites in Andes and NW Tierra del Fuego; some evidence of hybridization in latter, but the two species generally remain separate, and occupy different habitats. Small coastal race *minor* exhibits some plumage features intermediate between present species and *P. patagonicus*, and may be better included in latter on basis of its preference for forest or forest-edge habitat. Nominate race in extreme N of range has particularly large bill, suggesting clinal variation in bill size. Three subspecies recognized.

Subspecies and Distribution.

P. g. gayi (Gervais, 1834) – N & C Chile from Antofagasta S to Ñuble.

P. g. minor R. A. Philippi [Bañados] & Goodall, 1957 – coastal range in NC Chile from Atacama S to Valparaíso.

P. g. caniceps Burmeister, 1860 – W Argentina (S from W Salta) and S Chile (S from Aysen) S to Tierra del Fuego.

Descriptive notes. 15·5–16·5 cm; 21·9–30·7 g. Male nominate race has head to upper nape and upper chest bluish-grey, lores blackish; upperparts greenish-yellow; tail feathers blackish with bold blue-grey edging; upperwing-coverts blue-grey and flight-feathers dusky grey, broadly edged blue-grey (making wing appear extensively blue-grey); underparts yellowish, darker on breast, more clearly yellow on lower breast, with central belly to undertail-coverts white; iris dark reddish-brown; upper mandible blackish to grey, lower mandible pinkish-grey; legs dull flesh-coloured. Female has greyish head, streaked on crown and ear-coverts, slightly paler greyish supercilium, whitish submoustachial stripe that curls up behind ear-coverts, well-marked brown malar stripe broadening towards breast; upperparts dull grey with olive tone, very indistinctly streaked; wings and tail brownish, lacking blue-grey colours of male, wing-coverts fringed buffy grey; throat whitish, collar of streaks on upper breast, rest of underparts apricot-yellow, buffy on belly and vent, approaching whitish on undertail-coverts; bare parts as on male. Juvenile is like female, but duller in overall colour, and with buffy or cinnamon wingbars and wing edgings. Race *caniceps* is larger than nominate, with larger and thicker bill, less yellow than nominate, female with whiter throat and submoustachial stripe; *minor* is significantly smaller than nominate, male slightly warmer in tone on upperparts, female tending to have full hood extending to throat. Voice. Song a musical but repetitive series of notes, often in alternating pairs, e.g. "tweep-tseep, tweep-tseep, tweep-tseep, tweep-tseep"; less musical than song of *P. patagonicus*, and often deviating from alternating-pair pattern, doubling or even tripling one note before changing to other note type. Call a smacking "tack".

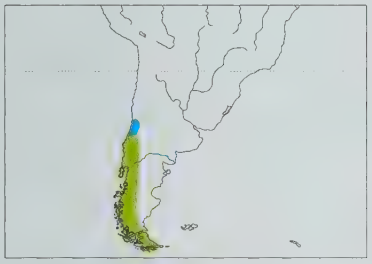
Habitat. Wide variety of open, shrubby areas. Rocky and shrubby slopes in Andean range; flatter sites dominated by shrubs such as *Berberis* in Patagonia. Where sympatric with *P. patagonicus*, as in Maule region of C Chile, present species found in shrub habitats and thickets, at higher elevations and ranging to rocky Andean slopes above tree-line, while its congener is strictly tied to forest and forest edge; similarly, in NW Tierra del Fuego, latter occupies sheltered areas where tree growth high enough to form forest patches, with present species in steppe habitats adjacent to these forest patches. On Chilean coast, race *minor* found in habitats with short trees, and thicker and more humid *matorral* in ravines immediately along coast, this habitat tending towards that of *P. patagonicus*. Sea-level to 3000 m.

Food and Feeding. Diet primarily seeds and invertebrates; may take fruit at times, especially calafate (*Berberis*) in late summer in Patagonian part of its range. In winter, seeds comprise 100% of food in C Chile. Forages on the ground. Generally in pairs or in small flocks; flocks form largely in non-breeding season, groups in summer tending to be family units.

Breeding. Season Oct–Feb. Solitary, but in certain situations neighbouring females may nest in very close proximity to each other. Nest placed in thick grassy vegetation, often beside stream, or low in thick bush, but in drier areas may be built on ledge or in crevice of rock outcrop. No data on clutch size; eggs pale blue with fine brown spots, these concentrated largely at wider pole. No other information.

Movements. Patagonian race *caniceps* moves N after breeding, sometimes reaching S Buenos Aires province of E Argentina. In C Chilean Andes, nominate race makes post-breeding shift downslope to foothills, or even into C valley.

Status and Conservation. Not globally threatened. Common throughout its extensive range. Occurs in various protected sites, including several national parks and national reserves. No known threats.



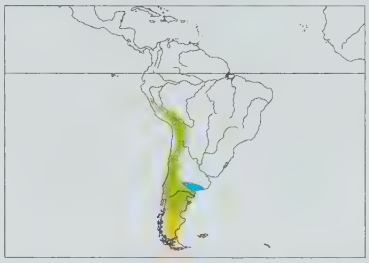
Bibliography. Armani (1985), Blendinger & Ojeda (2001), Estades (1997), Fjeldså & Krabbe (1990), Hellmayr (1932), Jaksic (1997), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Marín *et al.* (1989), McCarthy (2006), Ridgely & Tudor (1989), Vuilleumier (1991).

178. Patagonian Sierra-finch

Phrygilus patagonicus

French: Phrygile de Patagonie **German**: Magellanämmerling **Spanish**: Yal Patagón
Other common names: Patagonian Hooded Sierra-finch

Taxonomy. *Phrygilus gayi patagonicus* P. R. Lowe, 1923, Good Success Bay, Tierra del Fuego, Argentina.
Originally described as *Fringilla formosa*, but that name invalid, as preoccupied. Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species may form a superspecies with *P. atriceps*, *P. punensis* and *P. gayi* (the "hooded" group), and molecular data suggest that this group may be closely related to *Sicalis*. Range overlaps with that of *P. gayi* in various sites in Andes and NW Tierra del Fuego; some evidence of hybridization in latter, but the two species generally remain separate, and occupy different habitats. Small coastal race *minor* of *P. gayi* exhibits some plumage features intermediate between the two species, and may be better included in present species on basis of its preference for forest or forest-edge habitat. Monotypic.
Distribution. Breeds from Maule region of Chile S and from forested areas of adjacent Argentina (S from Neuquén) S to Tierra del Fuego. In winter also N to Valparaíso and Metropolitan Santiago regions.

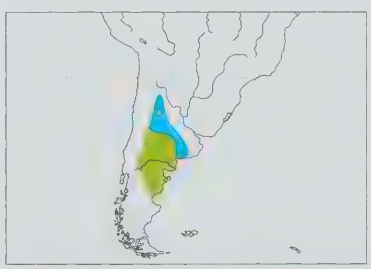


Descriptive notes. 14·5–15 cm; 19·1–27·4 g. Male has head to upper nape and upper breast blue-grey, lores blackish; upperparts russet, slightly more greenish near grey hood and contrastingly more yellowish on rump, uppertail-coverts blue-grey; tail feathers blackish with bold blue-grey edgings; upperwing-coverts blue-grey and flight-feathers dusky grey, broadly edged blue-grey (making wing appear largely blue-grey); underparts yellow, darker and with russet wash on breast and flanks, purer yellow on belly and vent, with undertail-coverts mostly white; iris chestnut; bill blue-grey, sometimes darker on culmen; legs dull pinkish. Differs from *P. gayi* in having much richer russet colour on back, warmer yellow tone on underparts, and white of undertail-coverts extending farther forwards (reaching to legs). Female is similar to male, with complete hood, but body coloration less intense, hood paler, and throat slightly paler, often with slightly darker malar stripe; also has darker upper mandible, bill not fully blue-grey. Juvenile is similar to female, but with darker malar stripe and paler greyish-white throat, underparts dull buffy yellow, upperparts more dull buffy olive; distinguished from extremely similar juvenile of *P. gayi* by less striking face pattern lacking pale supercilium and bold submoustachial and malar stripes. Voice. Song a musical but repetitive series of notes given in alternating pairs, "tweep-twop, tweep-twop, tweep-twop, tweep-twop"; more musical than song of *P. gayi*, and less likely to deviate from alternating-pair pattern. Call a smacking "tack".
Habitat. Various types of forest, including those dominated by southern beech (*Nothofagus*) and *Araucaria araucana*, as well as non-native forests such as eucalypt (*Eucalyptus*) and pine (*Pinus*) where some native understorey or middle storey remains. Frequent in interior of Patagonian forests, but most common at ecotones, roadsides, edges of clearings, near dwellings or in other openings adjacent to forest. Where sympatric with *P. gayi*, as in Maule region of C Chile, present species strictly tied to forest and forest edge, whereas its congener is found in shrub habitats and thickets, at higher elevations and ranging to rocky Andean slopes above tree-line; similarly, in NW Tierra del Fuego, found in sheltered areas where tree growth tall enough to form forest patches, while *P. gayi* occupies steppe habitats adjacent to these forest patches. Sea-level to 1500 m.
Food and Feeding. Seeds of grasses, also arthropods; also small forest fruits such as *Fuchsia magellanica*, *Berberis* and maqui (*Aristotelia chilensis*). Known to be a nectar robber of *Fuchsia magellanica*, reducing by 20% the seed production of plants pierced. Also feeds at sap holes produced by Magellanic Woodpeckers (*Campephilus magellanicus*). Widely observed to eat meat (jerky and bacon) left out to dry in the sun. Forages on ground, as well as in vegetation and trees. Usually in pairs; outside breeding season also in small flocks, sometimes mixed with other species.
Breeding. Season Nov–Feb. Nest a cup made from grasses, lined with softer material, usually placed in dense grasses or other vegetation on ground, or low down, but sometimes high up in *Nothofagus* tree, or in crevice in rock wall. Clutch 2–5 eggs, pale blue with fine brown spots, these concentrated at larger pole. No other information.
Movements. Mostly sedentary. Some move N after breeding, e.g. specimens from Metropolitan Region of Santiago, well N of breeding range, during winter months; similarly, some may retreat from higher elevations of Patagonian forest in winter, particularly during years with deep snow cover.
Status and Conservation. Not globally threatened. Common throughout its range. Present in various protected sites, such as national parks or national reserves, in both Chile and Argentina. As the forested habitats that this species prefers are well represented in the park systems of Chile and Argentina, a sizeable amount of habitat where it occurs is protected.
Bibliography. Armani (1985), Estades (1997), Fjeldså & Krabbe (1990), Hellmayr (1932), Housse (1945), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), McCarthy (2006), Ojeda & Trejo (2002), Ridgely & Tudor (1989), Schlatter & Vergara (2005), Traveset *et al.* (1998), Vuilleumier (1991).

179. Mourning Sierra-finch
Phrygilus fruticeti

French: Phrygile petit-deuil **German**: Strauchämmerling **Spanish**: Yal Pechinegro

Taxonomy. *Fringilla fruticeti* Kittlitz, 1833, Valparaíso, Chile.
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species appears to be sister to *P. carbonarius*, and studies suggest that the two should be placed together in a separate genus, for which the name *Rhopospina* is available. Three subspecies recognized.
Subspecies and Distribution.
P. f. peruvianus J. T. Zimmer, 1924 – Peru (S Cajamarca S to Puno) and W Bolivia (La Paz).
P. f. coracinus P. L. Sclater, 1891 – Altiplano of SW Bolivia (in Oruro and Potosí) and adjacent N Chile in regions of Arica–Parinacota (Visviri) and Tarapacá (Isluga).
P. f. fruticeti (Kittlitz, 1833) – Chile from (Arica–Parinacota S to Magallanes) and W Argentina (Salta S to Santa Cruz), largely in foothills of Andes.
Descriptive notes. 18 cm; 35·1–41·8 g. A stocky and rather large-bodied finch with long tail and medium-sized bill. Male nominate race has head grey, blackish lores, crown densely streaked blackish; upperparts grey, streaked from mantle to back (lower back and rump unstreaked); tail blackish, upperwing blackish, two well-formed white wingbars; chin to lower breast blackish, flanks greyish, upper flanks streaked, belly whitish, undertail-coverts white; appearance changes considerably with wear, in fresh plumage (after breeding season) pale brownish-buff above with dark streaks (brownish-buff feather tips gradually wearing away to reveal grey bases), black of throat and breast veiled with white, lesser coverts tipped grey, median and greater coverts edged brownish-buff, as are flight-feathers and tail feathers; iris brown; bill orange-yellow; legs dull orange. Female has



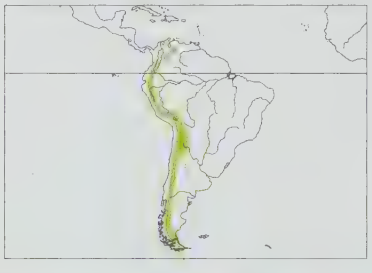
crown olive-grey with brownish streaking, pale grey supercilium, well-marked warm brownish ear-coverts bordered by white submoustachial stripe that extends backwards, side of neck greyish and often largely unstreaked (contrasting with ear-coverts); upperparts brownish-grey with darker streaking, lower back and rump unstreaked; tail brownish, upperwing brownish with two well-marked white wingbars, otherwise greater coverts and flight-feathers edged buff; throat whitish and narrowly streaked, bordered by well-defined blackish malar stripe and then whitish submoustachial area, underparts whitish, buffy on flanks, finely streaked on breast and flanks, belly white and unstreaked, undertail-coverts pale buff with very narrow streaks; bill and legs dull pinkish. Immature male is similar to female, but has darker face, and blackish throat and breast, broadly tipped white. Race *peruvianus* is smaller than nominate, with heavier streaking on upperparts, and in fresh plumage brighter and more rufous above; male *coracinus* is almost entirely blackish during breeding season. Voice. Song, from bush or in flight, very odd-sounding, loud, mechanical and buzzy, with rasping quality reminiscent of some marsh-nesting New World blackbirds (Icteridae), the buzz often preceded by short "chip" and followed by ringing note, "pik-chzzzzzéééééé chwip"; songs in C Chile higher-pitched and buzzier than those in N Chile, NW Argentina, Peru and Bolivia, and songs in Peru and N Chile lack introductory "chip" note. Call a nasal, wheezy "shweaaa".
Habitat. Variety of open and semi-open arid habitats. In Andean part of range inhabits shrubby slopes, including *Polylepis* forest edge, as well as cultivated areas, and in Patagonian steppes occupies flat shrub-steppe, often dominated by calafate (*Berberis*). In C Chile descends to agricultural areas, as well as open *matorral* habitats. Sea-level (Patagonian steppe, and in winter in C Chile) to 4000 m.
Food and Feeding. Diet a mix of seeds and invertebrates, and will take small fruit when available. In winter studies in C Chile, 98% of food was seeds and only 2% invertebrates. Forages on ground. In pairs or small flocks; almost exclusively in flocks during non-breeding season, but also in groups during breeding period.
Breeding. Breeds in spring and summer in much of range, Oct–Jan in C Chile, slightly later in Patagonia; fledglings in Dec in Bolivia (La Paz) and eggs hatch Apr–May in Peru. Breeding behaviour not studied; appears to be semi-colonial and lacks strong territoriality during breeding season, yet displays constantly almost as if in exploded lek; further study needed. In aerial display flies up to height of 4–10 m, and sings as it glides slowly downwards, with broadly spread wings and tail, wings being held below horizontal. Nest loose and untidy, made from grasses and lined with soft material, placed in dense low bush. Clutch 2–3 eggs, light green with olive-brown spots. No other information.
Movements. Populations in Peru, Bolivia, NW Argentina and N Chile presumed resident. Those in C Chile move to lower elevations in winter, and breeding population in far S retreats N into Argentina in winter. Vagrant in Falkland Is, with several records during Apr–Sept; vagrant reported also in SE Brazil (Rio Grande do Sul).
Status and Conservation. Not globally threatened. Common throughout its very extensive range. Occurs in various protected sites, such as national parks or national reserves, in much of range. No known threats.
Bibliography. Armani (1985), Fjeldså (1993), Fjeldså & Krabbe (1990), Grantsau (2002), Hellmayr (1932), Jaksic (1997), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Vuilleumier (1994), Woods (1988), Zimmer (1924).

180. Carbonated Sierra-finch
Phrygilus carbonarius

French: Phrygile charbonnier **German**: Schwarzbrustämmerling **Spanish**: Yal Carbonero

Taxonomy. *Emberiza carbonaria* d'Orbigny and Lafresnaye, 1837, Patagonia.
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Present species appears to be sister to *P. fruticeti*, and studies suggest that the two should be placed together in a separate genus, for which the name *Rhopospina* is available. Monotypic.
Distribution. Breeds in C Argentina from Córdoba, Mendoza, San Luis and W & SW Buenos Aires S to C & E Chubut. In non-breeding season ranges N to S Salta.

Descriptive notes. 14·5 cm; 16·1–18 g. A relatively small, long-tailed sierra-finch with thick-based, long conical bill. Male has face blackish, crown to back dark cold grey, streaked blackish, becoming washed with brown on unstreaked lower back to rump; upperwing and tail blackish with narrow dark grey edging, two inconspicuous narrow white wingbars; chin to undertail-coverts blackish, more greyish on flanks; in fresh plumage (autumn and into winter) has more extensive brownish coloration above and bolder wingbars; iris dark brown; bill bright yellow; legs flesh-coloured. Differs from similar *P. fruticeti* in smaller size, more extensive black below, less noticeable wingbars. Female is brownish-grey and streaked above; paler below, off-white with darker streaking; bill duller than in male. Immature male is similar to female, but with blackish throat to breast, and belly feathers tipped with buff, becoming increasingly blackish on underparts with wear. Voice. Song, in flight display, a high-pitched buzzy trill 2 seconds long, "tz-tz-tz-tz-tzee-tzee-tzee". Call a high "tiip".
Habitat. Shrubby Patagonian steppe during breeding; at other times various open shrubby habitats, sometimes at edge of agricultural areas or grasslands. In Mendoza, found during spring at roughly equal densities in open forest of *Prosopis flexuosa* and shrub habitat of *Larrea cuneifolia*, while in winter densities slightly higher in *Prosopis* forest.
Food and Feeding. Diet a mix of seeds and arthropods, proportion of latter increasing during breeding season. In Mendoza, 96% of seeds eaten were those of grasses (*Trichloris crinita* and *Sporobolus cryptandrus* together accounting for 49·2%), the rest being seeds of various forbs. Forages on ground. In pairs during breeding season; in small flocks during non-breeding period.
Breeding. Breeds during austral spring to summer, about Oct to Feb. In song flight male ascends as high as 15 m, and descends in gliding flight while giving buzzy trill. Nest semi-spherical, made



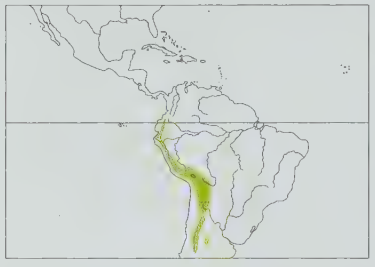
from dried grasses, placed on or near ground. Clutch 3 eggs, greyish-white with chestnut spotting. No other information.
Movements. Partially migratory, but details of movements unclear. Some of S populations, at least, move N between Apr and Sept; present in N part of range (San Juan and La Rioja N to Tucumán, Santiago del Estero and N Córdoba) only in winter months. In E Mendoza much more common in winter to early spring than during breeding season; further, it essentially disappeared between 1987 and 1988 during a period of drought, suggesting that some movements related to local rainfall.
Status and Conservation. Not globally threatened. Reasonably common throughout its large breeding range. Populations of this species probably under increased pressure owing to more industrialized agricultural practices, and removal of shrub habitats for agriculture. Its range is extensive, however, and no evidence that it is at any immediate risk. Its range includes at least two national parks, those of Sierra de las Quijadas and Lihué Calel.
Bibliography. Armani (1985), Couve & Vidal (2003), Harris (1998), Klicka *et al.* (2007), Marone (1992a, 1992b), Marone, de Casenave & Cueto (1997), Marone, de Casenave, Milesi & Cueto (2008), de la Peña (1989, 1996b), Ridgely & Tudor (1989).

181. **Plumbeous Sierra-finch**

Phrygilus unicolor

French: Phrygile gris-de-plomb **German**: Bleiämmerling **Spanish**: Yal Plomizo

Taxonomy. *Emberiza unicolor* d'Orbigny and Lafresnaye, 1837, Cordillera de Tacora, Tacna, Peru. Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Recent molecular data suggest a sister relationship between this species and *P. plebejus*, but distant relationship to other members of genus. Further, the two appear to be part of a clade that includes also *Haplospiza* and *Catamenia* (relationship with *Haplospiza* suggested by early authors on basis of similarities in plumage, as well as structure). Present species and *P. plebejus* should probably be placed together in separate genus, and *Geospizopsis* can be resurrected for them. Geographical variation complex. Races fall into three main groups, differing primarily in plumage tones: N group (*nivarius* and *geospizopsis*), males of which generally paler, females darker, boldly streaked and with strong buff wash below; single-species C group (*inca*), male with darkest plumage, female grey and male-like; and S group (*tucumanus*, nominate, *cyaneus* and *ultimus*), males intermediate in plumage, females duller brown and more obscurely streaked than N females. Proposed race *grandis* (described from Páramo de Santa Isabel, in C Andes of Colombia) supposedly larger than *geospizopsis*, but much overlap in measurements; treated as a synonym of latter. Seven subspecies recognized.
Subspecies and Distribution.
P. u. nivarius (Bangs, 1899) – N Colombia (Santa Marta Mts) and NW Venezuela (Mérida Andes).
P. u. geospizopsis (Bonaparte, 1853) – Andes of C & S Colombia (C & E ranges), Ecuador and N Peru.
P. u. inca J. T. Zimmer, 1929 – Peru S to W Bolivia (La Paz).
P. u. tucumanus Chapman, 1925 – C Bolivia (Cochabamba) S to NW Argentina (Jujuy S to La Rioja).
P. u. unicolor (d'Orbigny & Lafresnaye, 1837) – Chile (Arica–Parinacota S to Magallanes) and W Argentina (Mendoza S to Santa Cruz).
P. u. cyaneus Nores & Yzurieta, 1983 – highlands of Córdoba, in NC Argentina.
P. u. ultimus Ripley, 1950 – highlands of Tierra del Fuego.



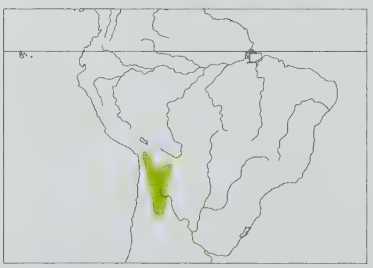
Descriptive notes. 14·5 cm; average 21·9 g. A medium-sized, stocky emberizid with relatively small bill. Male nominate race has lead-grey head and upperparts, throat and underparts only slightly paler, vent greyish-white; upperwing and tail blackish, feathers broadly edged grey (these areas appearing largely concolorous with body plumage); iris dark brown; bill and legs dark grey. Differs from *P. plebejus* mainly in distinctly larger size, and uniformly coloured plumage lacking paler supercilium and streaked upperparts. Female is mostly brown and strongly streaked: face, crown and upperparts brown with darker streaking, rump and lower back unstreaked brown with greyish wash; below, off-white with fine darker streaking throughout, from chin to undertail-coverts; wings and tail brownish; bare parts much as for male. Juvenile is like female, but darker brown, and more strongly streaked below. Race *geospizopsis* is larger and paler than nominate, female and some males with olive wash on ear-coverts; *nivarius* is slightly smaller than nominate, and darker grey on head and underparts; *inca* is darkest race, nearly sexually monomorphic, female only slightly duller grey than male and with slight tendency towards obscure streaking; *tucumanus* male is like nominate, but paler, and female more strongly streaked; *cyaneus* is similar to nominate, but somewhat paler, more bluish-grey; *ultimus* similar to nominate but larger, females with darker, more blackish streaks. Voice. Song a short sneezy "djeeeer"; song of S group, rarely given, is much more musical and attractive, a weak but far-carrying sweet wavering "swee-swee-swee-swee-sweeoo", with noticeable variations, but always repetitive notes with different ending. Calls a soft "chp" and a high-pitched feeble "zee".
Habitat. Open and grassy alpine habitats, ranging from wetter *páramo* in N, and *bofedal* wetlands (natural wetlands with spongy vegetation, or "cushion bogs") and edge in Altiplano, to dry rocky slopes and high-elevation grassland farther S. From 800 m in far S, to 5300 m in Altiplano and *páramo*.
Food and Feeding. A seed specialist; will also take invertebrates, particularly to feed to young. Forages on ground; in *páramo*, also flies up to *Espeletia* plants and feeds on seeds on the stalk. Usually in pairs, sometimes in small groups; may feed in association with *Diuca speculifera* and *P. erythronotus* or, farther S, with *P. gayi* and *Melanodera xanthogramma*.
Breeding. Season Nov–Jan in C Chile and Jan–Mar in N Argentina (Tucumán); fledglings Feb–Jul in Peru, and males in breeding condition Jul–Oct in Colombia. Nest made from grass and horsehair, finely woven, placed in crevice in rock wall or cliff, or in rocky scree area. Clutch 2–3 eggs, pale blue with brown spots, these concentrated at large pole. No other information.
Movements. Most populations resident; those in far S of range not well known, but presumably move to slightly lower elevations during winter months.
Status and Conservation. Not globally threatened. Common throughout its very extensive range. Occurs in various protected areas, such as national parks and national reserves, in most paarts of range. No known threats.
Bibliography. Armani (1985), Chapman (1915, 1925), Estrada & Rondan (2009), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Restall *et al.* (2006), Ridgely & Tudor (1989).

182. **Ash-breasted Sierra-finch**

Phrygilus plebejus

French: Phrygile plébéien **German**: Aschbrustämmerling **Spanish**: Yal Plebeyo

Taxonomy. *Phrygilus plebejus* Tschudi, 1844, no locality = highlands of Junín, Peru.
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). Recent molecular data suggest a sister relationship between this species and *P. unicolor*, but distant relationship to other members of genus. Further, the two appear to be part of a clade that includes also *Haplospiza* and *Catamenia* (relationship with *Haplospiza* suggested by early authors on basis of similarities in plumage, as well as structure). Present species and *P. unicolor* should probably be placed together in separate genus, and *Geospizopsis* can be resurrected for them. Three subspecies recognized.
Subspecies and Distribution.
P. p. ocularis P. L. Sclater, 1859 – Andes of Ecuador S to N Peru (N of Marañón Valley).
P. p. plebejus Tschudi, 1844 – Andes of Peru (S of Marañón Valley), N Chile (S to Antofagasta) and W Bolivia S to NW & WC Argentina (to Mendoza).
P. p. naroskyi Nores & Yzurieta, 1983 – NC Argentina (Sierra de Córdoba).



Descriptive notes. 11–11·5 cm; 13–17·4 g. A small, relatively short-tailed sierra-finch. Male nominate race has greyish face, paler grey on lores and supercilium; crown to back brownish-grey with darker streaking, lower back to uppertail-coverts unstreaked greyish; wing and tail brownish-grey; pale greyish-white below, flanks and breast slightly darker grey, undertail-coverts plain white; iris brown; bill black; legs blackish. Differs from *P. unicolor* in smaller size, less solidly grey plumage, streaking on upperparts, pale supercilium, and white belly. Female is similar to male, but browner and more extensively streaked: above, brownish with well-defined darker streaking, rump greyish and unstreaked; off-white below, streaked darker on breast and flanks, sides greyish-buff (less streaked below than female *P. unicolor*). Juvenile is similar to female, but duller. Race *ocularis* is smallest, overall greyer and less streaked above; *naroskyi* is more greyish, less brownish, than nominate, with noticeably darker flanks, wings and tail blackish (rather than brownish-grey), also smaller in size. Voice. Song a high-pitched, insect-like dry trill followed by shorter "chip" notes, "tzzzzzzzz chip chipa chipa chipa", or similar but with sweeter terminal notes, "tzzzzzzzz swee sweet sweet sweet"; N race *ocularis* gives buzzy trill, but no terminal notes. Call a high "tiip".
Habitat. Various open highland habitats, from flat dry grassy *puna* to rocky slopes, edge of *bofedal* wetlands ("cushion bogs"), open *Polylepis* woodlands and edge, also desert highlands and cactus-clad slopes. Thrives in sparsely vegetated habitats, including anthropogenic ones such as overgrazed regions, and near villages and settlements in highlands. Rather tolerant of arid conditions; also of overgrazed and very sparse habitats. Mainly 2500–5000 m; also down nearly to sea-level in Tumbesian region of S Ecuador and extreme NW Peru.
Food and Feeding. Primarily seeds, also arthropods. Forages in small flocks on ground; sometimes in mixed flocks with *Sicalis olivascens*.
Breeding. Season Oct–Jul, apparently timed to coincide with end of dry season, e.g. Oct–Nov in N Chile, Oct in Bolivia, Jun–Jul in S Peru (and Mar–Apr in Cuzco). Nest a messy structure of grass, hair, wool and feathers, reminiscent of bulky nest of House Sparrow (*Passer domesticus*), placed in crevice, under eave of adobe house, or even under large rock on ground, sometimes 20–30 cm above ground in clump of bunch-grass or in small bush. Clutch 2 eggs, pale blue-green with dark brown spots, these concentrated at wide end. No other information.
Movements. Appears to be sedentary.
Status and Conservation. Not globally threatened. Common or very common throughout its large range. Occurs in some protected areas, such as Lauca National Park and Las Vicuñas National Reserve (N Chile). No evidence that this species is suffering any decline in numbers.
Bibliography. Armani (1985), Dunning (2008), Fjeldså & Krabbe (1990), Hughes (1980), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Nores & Yzurieta (1983), Ridgely & Tudor (1989), Roe & Rees (1979), Schulenberg *et al.* (2007), Vuilleumier (1969a).

183. **Red-backed Sierra-finch**

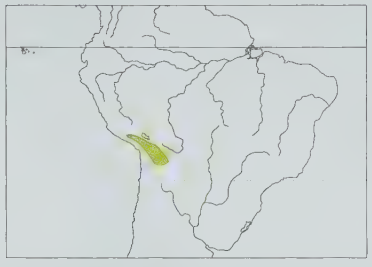
Phrygilus dorsalis

French: Phrygile à dos roux **German**: Braunmantelämmerling **Spanish**: Yal Dorsirrojo

Taxonomy. *Phrygilus dorsalis* Cabanis, 1883, Cerro Bayo, near snow-line, Tucumán, Argentina.
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). May form a superspecies with *P. erythronotus*, and has been suggested as being conspecific; hybridization between the two reported, although without specimen evidence or a detailed analysis. Recent molecular results indicate that this species (*P. erythronotus* not sampled) is sister to the "hooded" group (*P. atriceps*, *P. punensis*, *P. gayi* and *P. patagonicus*) and *Sicalis*; more study required. Monotypic.
Distribution. N Chile (Andes of Tarapacá and Antofagasta), SW Bolivia (S from Oruro) and NW Argentina (Jujuy, Salta, Tucumán and Catamarca).

Descriptive notes. 15 cm; 35·4–40·5 g. A stocky finch with thick and rather triangular-looking bill. Head and upper nape are blue-grey, usually speckled white below eye, mantle and upper back contrastingly brick-red, lower back, rump and uppertail-coverts grey (like head); upperwing and tail blackish, in fresh plumage flight-feathers edged rusty; throat white, breast grey, flanks warmer with buff tone, belly whitish; iris dull reddish; bill and legs dark grey. Sexes alike. Juvenile is rather duller than adult, back browner and with obvious dark streaks. Voice. Song apparently remains unrecorded. Calls include a short "wheenk" and a nasal "phew".

Habitat. Typically found in *bofedales* (Altiplano wetlands, or "cushion bogs") adjacent to dry rocky *puna* slopes, also moister patches of *puna* grassland interspersed with tola (*Lepidophyllum quadrangulare*). Appears to prefer drier sites than those occupied by *P. erythronotus*. Recorded at 3300–4500 m.
Food and Feeding. Little known. Diet largely seeds, also arthropods. Forages in pairs or family groups on ground; often forages in crouched posture, with legs nearly hidden.
Breeding. Season Feb–May. Aerial display described in which bird rises some distance, hovers at apex and descends in fluttering flight like that of pipit (*Anthus*), either silently or while giving "wheenk" note. Nest loose, semi-spherical in shape, with large component of wool, hair and feathers, placed in crevice or inside rock pile in rocky outcropping. Clutch up to 3 eggs. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally uncommon and local. Present in some protected sites, such as national parks and national reserves; e.g. occurs in Reserva Nacional de Fauna Andina Eduardo Avaroa (Bolivia), where it is common. No evidence that this species is suffering any decline in numbers.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), McCarthy (2006), Philippi (1940), Ridgely & Tudor (1989), Rocha & Quiroga (1996).



184. White-throated Sierra-finch

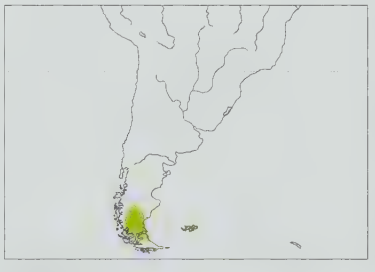
Phrygilus erythronotus

French: Phrygile bicolore **German**: Weißkehlämmerling **Spanish**: Yal Gorjiblanco

Taxonomy. *Chlorospiza erythronotus* R. A. Philippi [Krumwiede] and Landbeck, 1861, Parinacota, 10,000–17,000 feet [c. 3050–5200 m], Arica, Chile.
Molecular-genetic studies indicate that genus belongs in tanager family (Thraupidae). May form a superspecies with *P. dorsalis*, and has been suggested as being conspecific; hybridization between the two reported, although without specimen evidence or a detailed analysis. Recent molecular results indicate that *P. dorsalis* is sister to the "hooded" group (*P. atriceps*, *P. punensis*, *P. gayi* and *P. patagonicus*) and *Sicalis*, and this may apply also to present species (not sampled); more study required. Monotypic.

Distribution. S Peru (from SE Arequipa and S Puno) S to N Chile (highlands of Arica–Parinacota region) and SW Bolivia (W Oruro and W Potosí).

Descriptive notes. 16 cm. A relatively large finch, stocky-bodied but relatively long-tailed. Has head and upperparts to uppertail-coverts lead-grey, inconspicuous white streaking on ear-coverts and below eye, obscure darker streaks on crown and back; tail blackish with narrow pale edges; upperwing blackish with pale edging, the edges most obvious on primaries, and the dark wing contrasting with paler greyish body feathering; chin and throat white, surrounded by grey, which extends down to side of throat and across breast; lower breast to undertail-coverts white; wing-linings to marginal coverts white, sometimes showing as white wing edge on perched bird; iris dark chestnut; bill and legs blackish. Distinguished from superficially similar *Diuca speculifera* by smaller size, lack of bold white wing patch and white spot below eye, and lack of white tail sides. Sexes similar. Juvenile is similar to adult, but back washed warm brownish and streaked; very like juvenile of *P. dorsalis*, but back on average duller brown, not so reddish. Voice. Song unrecorded. Calls include short "wheenk" and nasal "phew".
Habitat. Preferred habitat moist *bofedal* wetlands ("cushion bogs") adjacent to rocky slopes with piled boulders or large rocks; feeds at edge of *bofedal*, flies up to rocky slope when alarmed. Generally in moister sites than those preferred by *P. dorsalis*. At 3600–4700 m.
Food and Feeding. Little known. Feeds largely on seeds, with smaller component of invertebrates. Forages in pairs or family groups on ground.
Breeding. No information. Season presumably Mar–May.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon. Occurs in some protected sites, such as Lauca National Park and Las Vicuñas National Reserve (N Chile). No evidence that this species is suffering any decline in numbers.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), McCarthy (2006), Philippi (1940), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).



Genus *MELANODERA* Bonaparte, 1850

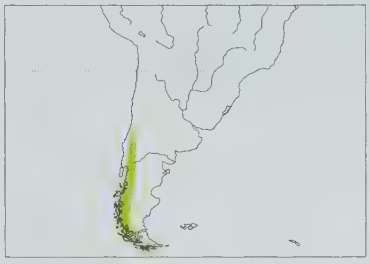
185. Canary-winged Finch

Melanodera melanodera

French: Mélanodère à sourcils blancs **Spanish**: Yal Cejiblanco
German: Schwarzkehl-Ammerfink
Other common names: White-bridled/Black-throated Finch; Falkland Black-throated Finch (*melanodera*)

Taxonomy. *Emberiza melanodera* Quoy and Gaimard, 1824, Falkland Islands.
Likely that genus belongs within tanager family (Thraupidae), but molecular data needed to support this assertion. Some morphological and plumage features suggest relationship with *Rowettia*. Races well differentiated, geographically isolated from each other, and perhaps better treated as two separate species; further work required. Two subspecies recognized.
Subspecies and Distribution.
M. m. princetoniana (W. E. D. Scott, 1900) – S Chile (Magallanes) and S Argentina (Santa Cruz and Tierra del Fuego).
M. m. melanodera (Quoy & Gaimard, 1824) – Falkland Is.
Descriptive notes. 14–15 cm; 25–35 g. A medium-sized and thickset emberizid with strongly triangular bill shape and very long wings. Male nominate race has mostly grey head with complex pattern of black lores, white supercilium from supraloral area to above ear-coverts and white band extending from base of malar region backwards to meet rear supercilium (thus, lores and dark eye surrounded above and below by white), and black throat surrounded by long white malar stripes which meet narrow white band across upper chest; upperparts olive to greenish-grey (greenish feather tips), rump more solidly greenish; tail and upperwing mainly yellow-olive, narrow yellow edging on primaries and rectrices; underparts dull yellow, with grey side of breast and flanks, white on rear belly and undertail-coverts; wing-linings yellow; iris dark brown; upper mandible blackish, lower mandible largely blue-grey; legs blackish. Female has whitish area around eye, brownish ear-coverts with buff streaking, pale yellowish-buff submoustachial stripe; crown and upperparts brownish-olive with broad darker streaks; tail brownish, outer two feather pairs with yellow base and white tips, next pair with restricted yellow base and no white on tip; wing brownish, primaries with yellow edges, tertials broadly edged yellowish-buff; throat whitish with small dark streaks, narrow dark malar stripe, otherwise whitish below, breast and flanks with dark streaks, some yellow on mid-belly, whitish vent and undertail-coverts; bare parts as on male. Juvenile resembles female, but more heavily streaked, with less yellow and green in plumage, duller bill; immature male similar to female, but more extensively yellow on wing and tail, and may show greenish on breast side and greyish face. Race *princetoniana* is brighter than nominate, grey areas of plumage tending more towards blue-grey, flight-feathers broadly edged yellow and with extensive yellow at bases, wing-coverts largely yellow and wing-linings yellow (in flight, wings flash an intense canary-yellow), tail similarly yellow on edges and base (in flight, also appears extensively yellow), yellow on underparts brighter and more extensive. Voice. Song of *princetoniana* a lively melodious, yet repetitive series of notes with intervening gaps only slightly longer than each note, "swee twee swee stweee towee twk swee..."; similar to that of *M. xanthogramma* (of race *barrosi*), but faster, livelier and slightly higher-pitched. Song of nominate race, given largely between Sept and Dec, a plaintive repetition of two or three phrases, e.g. "peeoo-payoo-payoo...". Call a soft, high-pitched "tsip".

Habitat. On mainland found in open grassland of perennial bunch-grass sometimes known as "tussock" or "coirón" (various species of *Stipa*, *Poa ligularis*, and *Bromus pictus*), from sea-level to 500 m. In Falklands, found in heathland with dwarf shrubs, grassy areas by beaches, and dunes with marram grass (*Ammophila arenaria*) and tussac (*Poa flabellata*) grassland; occurs up to at least 150 m.
Food and Feeding. Seeds and arthropods; in Falklands feeds on seeds of grasses, sorrel (*Rumex*), chickweed (*Stellaris media*), sand cabbage (*Senecio candicans*) and diddle-dee (*Empetrum rubrum*), and will also take flowers. Forages on ground; will also take seeds from grass seedheads. Singly or in pairs during breeding; in flocks of up to c. 20 individuals in non-breeding season, and flock of c. 1000 once observed in Falklands. In Magallanes (S Chile), in winter, may mix with *M. xanthogramma* in grassy steppe near sea-level.



Breeding. Season Oct–Jan on mainland; in Falkland Is egg dates mid-Sept to late Dec; probably double-brooded in Falklands. Nest built mainly by female, made from fine grasses, lined with feathers and horsehair, placed on ground in grass clump or in crevice between stones, in Falklands occasionally on top of tussac grass. Clutch 3–4 eggs, pale blue-grey or greenish-grey with purple-brown spots, these concentrated around wide end. No other information.
Movements. On mainland, vacates higher-lying breeding sites (such as highlands above Porvenir, in Tierra del Fuego) and winters closer to coast, but remains at roughly same latitudes as during breeding. Sedentary in Falkland Is.
Status and Conservation. Not globally threatened. Uncommon or scarce to locally common. Fairly common and widespread in Falkland Is, where estimated population 7000–14,000 pairs in 1983–1993. Mainland population small, and appears to have suffered long-term decline probably as a result of overgrazing; native grass communities under pressure from overgrazing by sheep, and where grass becomes too short or too sparse this emberizid abandons the area. Whether decline is continuing or has been reversed because of lower numbers of sheep in Patagonia since end of 20th century remains to be studied.
Bibliography. Armani (1985), Dunning (2008), Gould (1839), Humphrey *et al.* (1970), Jaramillo (2003), Johnson & Goodall (1967), Pettingill (1973), Ridgely & Tudor (1989), Shirihai (2002), Woods (1988).

186. **Yellow-bridled Finch**

Melanodera xanthogramma

French: Mélanodère à sourcils jaunes **German**: Zügelammerfink **Spanish**: Yal Cejiamarillo
Other common names: Andean Yellow-bridled Finch (*barrosi*)

Taxonomy. *Chlorospiza* (?) *xanthogramma* Gould and G. R. Gray, 1839, East Falkland Island and Tierra del Fuego.
Type description includes Falkland Is, possibly indicating misidentified immature of *M. melanodera*, but this considered unlikely, as morphological and ecological differences between the two species in Falklands already well described at the time; no recent records of present species from Falklands, where presumably now extirpated. Likely that genus belongs within tanager family (Thraupidae), but molecular data needed to support this assertion. Some morphological and plumage features suggest relationship with *Rowettia*. Races well differentiated both in coloration and in size, and further work may suggest that they are better treated as two separate species. Shows a peculiar polymorphism, some birds being extensively washed green above and yellow below, others not; distribution and significance of this "green morph" not well understood. Two subspecies recognized.
Subspecies and Distribution.
M. x. barrosi Chapman, 1923 – Andes of C & S Chile (Atacama S to Magallanes N of Strait of Magellan) and WC & SW Argentina (Mendoza S to Santa Cruz).
M. x. xanthogramma (Gould & G. R. Gray, 1839) – Tierra del Fuego (extreme S Chile and S Argentina).
Descriptive notes. 15–17 cm; 35–37 g. A relatively large finch, thickset, with very long wings and strongly triangular bill. Male nominate race has complex facial pattern, with black lores (and dark iris) bordered above by narrow yellowish half-supercilium and below by yellowish eye-crescent, and greenish to greyish ear-coverts and crown, also distinct black throat patch bordered laterally

by yellowish malar stripes and below by paler yellow fringe on lower edge of throat; upperparts plain grey, tail greyish-brown, outer two rectrices largely yellow; upperwing greyish-brown, upperwing-coverts greyish, greater (and sometimes median) coverts with greenish or yellow wash, primaries edged yellowish, secondaries edged grey; underparts grey, with yellowish-white belly, and white vent and undertail-coverts; some individuals (green morph) have strong greenish-olive tone on crown and upperparts, and bright yellow belly; iris dark brown; bill and legs blackish. Female is strongly streaked brownish, has crown and upperparts brownish with darker streaks, face with paler buff around eye, buff ear-coverts with brown streaking; tail brownish, extensive whitish on inner web of outer rectrix; upperwing brownish, pale buff fringes on coverts and flight-feathers; throat whitish with small dark streaks, narrow dark malar stripe; breast and flanks buff, strongly streaked brown, otherwise whitish below; bare parts as on male; green-morph female is richer brown all over, with white areas of underparts replaced by bright yellow. Juvenile resembles female, but more heavily streaked; immature male similar to female, but may show blackish throat patch finely tipped buff on each feather, also less extensively streaked below, with yellowish central belly. Race *barrosi* is substantially larger than nominate, tail markings white (not yellow), upperwing-coverts greyer, lesser coverts with more greenish tone, primaries edged greyish (not yellow). Voice. Song of race *barrosi* is a lazy and slowly delivered melodious series of sweet notes, with gaps between notes longer than notes themselves, "feee...swee...twu...feee...suuwee...twu..." seemingly uttered continuously. Song of nominate similar, but noticeably buzzier, slightly faster and higher-pitched. Call a soft, high-pitched "tsip"; also gives quick high-pitched series of 4–8 notes on descending scale, "tsi-ti-ti-ti-tit".
Habitat. Breeds above tree-line in very sparsely vegetated to grassy alpine habitats interspersed with rocks; up to 600 m in S and 3500 m in N. Non-breeding habitat also open and grassy, and includes sea and lake shorelines, thus down to sea-level in winter.
Food and Feeding. Takes seeds and arthropods; in spring often feed on petals of introduced dandelions (*Taraxacum*). Forages on ground; in early spring, forages at edge of melting snow in manner of a rosy-finch (*Leucosticte*). In pairs during breeding season, also in small flocks at other times; in Magallanes (S Chile), in winter, may mix with *M. melanodera* in grassy steppe near sea-level.
Breeding. Season Oct–Jan, young fledging Nov–Jan. Nest concealed under boulder or hidden in grass on ground. No other information.
Movements. Descends to lower elevations during winter, or during late-spring snow storms; details of movements not known. In Tierra del Fuego, nominate race makes post-breeding descent and moves to lower grassy steppe habitats in N part of the island.
Status and Conservation. Not globally threatened. Uncommon to scarce, and patchily distributed. This species' mountain-top alpine habitat may be severely threatened by global warming; regular monitoring in order to detect any population changes is warranted.

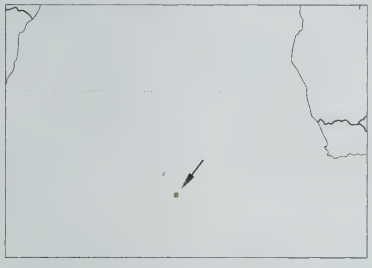
PLATE 58

inches 2

cm 5



Genus *ROWETTIA* P. R. Lowe, 1923

187. **Gough Finch**

Rowettia goughensis

French: Rowettie de Gough **German**: Goughammerfink **Spanish**: Yal de Gough
Other common names: Gough Island Finch, Gough Bunting

Taxonomy. *Nesospiza goughensis* W. E. Clarke, 1904, Gough Island.
Sometimes placed in genus *Nesospiza*, but exhibits affinities also with *Melanodera*. Morphological and genetic evidence indicate that this species belongs with the Neotropical finches, distant from Old World *Emberiza*. Monotypic.
Distribution. Gough I, including vegetated offshore stacks, in S Atlantic.

Descriptive notes. 23–26 cm; 50–56 g. A large, handsome finch with long, relatively slender bill. Male is mostly olive-green, with black lores and bib highlighted by pale, yellowish supercilium, broken eyering, and indistinct submoustachial area; flight-feathers dark olive-brown with yellowish-olive outer margins; below, greenish of breast becomes somewhat more yellowish on belly; iris dark brown; bill blackish; legs dark grey. Female is on average slightly smaller than male, also slightly duller and with brownish facial markings, paler buffy-olive upper breast and stronger grey tinge on upperparts. Juvenile is mostly sandy buff with dark brown streaking on head, back and underparts, with rump richer buff with less heavy streaking, and margins of flight-feathers more yellow; some retain juvenile plumage for at least two years; immature similar to adult female, but facial markings indistinct and retains some blackish-brown streaking on contour feathers, rump tinged buff, immature male with more prominent dark facial markings than immature female. VOICE. Male advertises territory with high-pitched whistled song, "tsweeeep"; female responds with deeper chattering call, often duetting with male. Soft contact call "keet keet"; when Brown Skua (*Catharacta antarctica*) flies over, utters distinct alarm call while standing erect (head and bill pointing skywards); breeding female has distinctive swizzling call when soliciting food from male at nest.
Habitat. Occurs in most habitats from boulder beaches to highest mountain peaks, 900 m above sea-level; mostly in uplands, above 300 m. Most common in tussock grassland, wet heath and fjeldmark; now rare at lower elevations in fernbush and peatbogs.
Food and Feeding. Diet includes insects, spiders (Araneae), seeds and berries. Seeds mainly of sedges (*Carex insularis*, *Carex thouarsii*, *Scirpus sulcatus*, *Scirpus bicolor*, *Uncinia compacta*) and grasses (*Agrostis*, *Calamagrostis*, *Deschampsia*, *Holcus lanatus*, *Poa annua*); berries include especially fruits of *Nertera depressa*. Forages by gleaning from vegetation, including from epiphytic lichens growing on *Phylica arborea* trees and from stems of *Blechnum palmiforme* tree-ferns. Often pulls up moss and other loose vegetation with bill or feet to expose prey. Also tears apart rotten wood; occasionally hawks flying insects. Enters seabird burrows, and forages on insects associated with stranded seaweed on boulder beaches. Occasionally scavenges from skua kills.
Breeding. Season Sept–Dec (mainly Oct–Nov), starting earlier at lower elevations; one exceptional record of laying in Aug; single-brooded. Pair defends breeding territory. Nest built by female, a deep cup made from long grass and sedge leaves (material gathered close to nest-site), lined with finer vegetation, placed in dense vegetation on or close to ground, often on steep slope or cliff; historical records of nests built up to 1 m above ground in head of *Blechnum palmiforme* tree-fern in fernbush vegetation, but no recent records (species is virtually extinct in this habitat type). Clutch 2 eggs, rarely 1 or 3, light blue, finely speckled dark brown; may lay replacement if first clutch fails; incubation by female, fed near nest by male on average every 20–25 minutes, female also leaves eggs for brief foraging stints lasting 5–10 minutes; no information on duration of incubation period; chicks brooded by female only, male feeds female but does not feed chicks directly, both parents provision chicks once they are alone in nest, nestling period 20–26 days; young remain in dense cover near nest for a further week or so, then accompany foraging adults. Breeding success average: just over half of all clutches produce at least one chick; average of 0·87 fledglings per breeding attempt. As population decreases, more pairs include individuals in immature or even juvenile plumage, although breeding by juveniles yet to be confirmed.
Movements. Resident. Among ringed individuals (including fledglings), maximum recorded movement over periods of up to 7 years was 1·8 km.
Status and Conservation. CRITICALLY ENDANGERED. Rare to locally fairly common. Breeding population currently estimated at only 400–500 pairs, with total population of 1050–1350 individuals. The only passerine resident on Gough I (91 km²), where formerly abundant. Numbers have decreased since at least mid-20th century, especially in lowlands, apparently as a result of nest predation by introduced house mouse (*Mus domesticus*); still abundant on Penguin I, a mouse-free offshore stack. Mouse predation has driven this species away from coastal areas into suboptimal upland habitat, and is causing very rapid decline in its numbers; it is now rare at lower elevations in fernbush. Number of territory-holding individuals in immature and juvenile plumages has increased, suggesting that there are many vacant territories as population shrinks; at same time, proportion of juveniles in whole population has decreased greatly, indicative of reproductive failure and an ageing population. Introduced mice are significant predators also of seabird chicks on Gough I, and a plan is being formulated to attempt to eradicate mice from the island; initial results from a feasibility study of mouse removal appear promising. Gough is a nature reserve and World Heritage Site, and human population consists of a small number of staff at a meteorological station.

Genus *NESOSPIZA* Cabanis, 1873

188. **Inaccessible Finch**

Nesospiza acunhae

French: Nésospize de Tristan da Cunha **Spanish**: Yal de la Inaccesible
German: Tristanammerfink
Other common names: Inaccessible Bunting; Lowland Finch (*acunhae*); Upland Finch (*fraseri*); Dunn's Finch (*dunnei*); Tristan Bunting/Finch (when treated as conspecific with *N. questi* and/or *N. wilkinsi*)

Taxonomy. *Nesospiza acunhae* Cabanis, 1873, Tristan da Cunha.
Genus is closest to Neotropical finches, distant from Old World *Emberiza*. Genus confined to Tristan da Cunha island group, where it has undergone an adaptive radiation. Nominate race and *fraseri* formerly considered conspecific with *N. questi* of Nightingale I, but genetic evidence suggests independent evolution on each island. Races of present species breed assortatively in coastal habitats, where large-billed *dunnei* and small-billed, drab nominate race behave as distinct species (distinct songs, and territorial behaviour focused primarily on members of own race); in contrast, all three races interbreed in ecotone between *Blechnum* heath and *Phylica* woodland on the plateau. Three subspecies recognized.
Subspecies and Distribution.
N. a. acunhae Cabanis, 1873 – coastal scarps of Inaccessible I, in S Atlantic.
N. a. fraseri Ryan, 2008 – plateau of Inaccessible I.
N. a. dunnei Hagen, 1952 – coast and E plateau of Inaccessible I.

Descriptive notes. 17–21 cm; 24–49 g. An exceptionally variable species. Male nominate race is olive-green above and paler olive-grey below, with yellowish forecrown and throat; lores and feathers around eye pale grey; flight-feathers dark olive-brown with yellow-olive outer margins; iris dark brown; bill and legs dark grey. Female is on average slightly smaller than male, also duller and more streaked above. Juvenile and immature are even more heavily streaked than female. Race *fraseri* is brighter green above and more intensely yellow below than nominate, is on average larger in head, wing and tarsus length, but smaller bill; *dunnei* is about two-thirds larger than nominate and previous, and has much larger, deeper bill. VOICE. Male song a repeated phrase of 3–4 notes, "whit it teeu", more varied than that of *N. questi*; song of race *dunnei* deeper and slower than those of other races, and hybrids have distinct song. Females have subdued, querulous whistle. Both sexes give a chipping contact call, also alarm call when skua (*Catharacta*) appears.
Habitat. Nominate race largely confined to coastal lowlands and cliffs dominated by *Spartina arundinacea* tussock grassland; replaced on the plateau by *fraseri*, although some immatures of this race feed along coast in winter and spring. Race *dunnei* largely confined to areas of tall *Phylica arborea* woodland, where there is abundant fruit. All three races interbreed in ecotone between *Blechnum* heath and *Phylica* woodland on the plateau.
Food and Feeding. Diet mainly seeds, fruits and invertebrates. Small-billed nominate race eats seeds of *Spartina* and other grasses, sedges and forbs, as well as invertebrates; often forages on flies (Diptera) in intertidal zone and among stranded seaweeds. Race *fraseri* eats mainly sedge seeds and *Nertera* fruit, as well as invertebrates; its brighter plumage apparently results from greater intake of carotenoids, linked to dietary differences (between food provided by fernbush vegetation on the plateau and that of *Spartina* tussock grassland on coastal scarps). Race *dunnei* and large-billed hybrids feed mainly on *Phylica* fruit, although they also take invertebrates. Hybrids often glean insects from epiphytes on *Phylica* trees on E plateau. Chicks fed with caterpillars and other invertebrates; chicks of *dunnei* fed with *Phylica* fruit from an early age. Forages on various substrates, from bark, foliage and lichens to flowers, boulders and ground.
Breeding. Season Nov–Feb; single-brooded. Usually monogamous, and partners remain together for successive breeding attempts; one male of nominate race had two females on adjacent territories. Possible helper at one nest of race *dunnei*. Territorial, both sexes repelling intruders. Nest built by female, a cup made from grass and sedge leaves, placed in dense vegetation, usually close to ground, sometimes up to 1·2 m up in dense *Spartina* tussock. Clutch 1–2 eggs (average 1·8), light blue, finely speckled dark brown; may lay several replacements following failures; incubation by female, fed near nest by male, period 17–18 days; chicks brooded by female for first 5–7 days, after which both parents feed chicks, both also remove faecal pellets when chicks small, but allow these to accumulate on nest rim when chicks large, nestling period 18–21 days; fledglings remain in dense cover for 10 days after leaving nest, then accompany adults for up to 6 weeks. Main causes of failure are predation by Tristan Thrush (*Nesocichla eremita*), also inclement weather; starvation possibly a problem for *dunnei*, which have much lower breeding success (only 13% of eggs result in fledglings) than small-billed birds and hybrids (52%).
Movements. Mostly resident. Some immatures of race *fraseri* apparently forage along coast in winter, returning to the plateau in Sept–Oct.
Status and Conservation. VULNERABLE. Restricted-range species: present in Tristan Islands EBA. Abundant and widespread on Inaccessible I (14 km²), with estimated 10,000 pairs. Population of nominate race on main island of Tristan disappeared within 50 years of settlement, probably as a result of predation by introduced house mice (*Mus domesticus*) and feral cats (*Felis catus*). Density varies with habitat, up to 18 pairs/ha in coastal tussock, but only 2–6 pairs/ha on the plateau. Although this species is very numerous within its extremely small range, and is thought not currently to be declining, the possible arrival of invasive species could rapidly result in steep decline in its numbers, potentially leading to extinction within a short time period (as has happened on Tristan da Cunha). Paradoxically, Inaccessible I has become far more accessible with arrival of several motorized boats on Tristan, increasing risk of accidental introduction of mammalian predators and

Cinereous Finch (*Piezorina cinerea*); 201. Slender-billed Finch (*Xenospingus concolor*).

other invasive species. A further threat is invasion of introduced New Zealand flax (*Phormium tenax*) into areas of *Phylica* woodland, leading to degradation of habitat.
Bibliography. Abbott (1978), Anon. (2010c), Armani (1985), Bourne & David (1981), Butchart & Stattersfield (2004), Carmichael (1819), Collar & Stuart (1985), Elliott (1957), Fraser & Briggs (1992), Hagen (1952), Lack (1947), Lowe (1923), McCarthy (2006), Rand (1955), Richardson (1984), Ryan (2001, 2007, 2008), Ryan & Moloney (2002), Ryan, Bloomer *et al.* (2007), Ryan, Moloney & Hudon (1994), Shirihai (2002), Stattersfield & Capper (2000).

189. **Nightingale Finch**

Nesospiza questi

French: Nésospize du Quest **German**: Questammerfink **Spanish**: Yal de la Nightingale
Other common names: Nightingale Bunting; Tristan Bunting/Finch (when treated as conspecific with *N. acunhae* and/or *N. wilkinsi*)

Taxonomy. *Nesospiza acunhae questi* P. R. Lowe, 1923, Nightingale Island, Tristan da Cunha Group.
Genus is closest to Neotropical finches, distant from Old World *Emberiza*. Genus confined to Tristan da Cunha island group, where it has undergone an adaptive radiation. Usually considered conspecific with small-billed races (nominate and *fraseri*) of *N. acunhae* of Inaccessible I, but genetic evidence suggests independent evolution on each island. Cytochrome *b* sequence of present species appears identical to that of *N. wilkinsi*, but the two are highly distinct in terms of morphology and behave as separate species, with distinct vocal systems and no evidence of hybridization between them. Monotypic.
Distribution. Nightingale I, including offshore islets of Alex (Middle) and Stoltenhoff, in S Atlantic.

Descriptive notes. 16–18 cm; 24–29 g. Male has face and lores pale grey, rest of head and upperparts yellow-olive, finely streaked dark brown (mainly on crown and mantle); flight-feathers grey-brown, fringed yellow-olive; yellow-olive below, brightest on throat; iris dark brown; bill and legs dark grey to blackish. Differs from *N. wilkinsi* mainly in appreciably smaller size and much smaller bill. Female is on average slightly smaller than male, also duller and slightly more streaked. Juvenile and immature resemble female, but are buffy brown and more heavily streaked. Voice. Male advertises territory with high-pitched, sharp song, "whit-wheu whit-wheu..." repeated monotonously; female has subdued, querulous whistle. Both sexes give a chipping contact call, also alarm call when skua (*Catharacta*) appears.
Habitat. Throughout Nightingale and adjacent islets, from rocky shoreline to highest peaks. Most abundant in *Spartina arundinacea* tussock grassland and *Scirpus*-dominated areas around The Ponds (in centre of island).
Food and Feeding. Diet mainly seeds and berries; also some invertebrates. Forages on plants and on the ground.
Breeding. Little known. Breeds in Nov–Jan. Nest an open cup, built low down among dense vegetation, usually sedges (Cyperaceae) or grasses, occasionally among ferns. Clutch 1–2 eggs (report of 4–5 eggs in a clutch almost certainly erroneous), light blue, finely speckled dark brown. No other information.
Movements. Presumably resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Tristan Islands EBA. Abundant; global range tiny, c. 4 km². Total population estimated at no more than c. 5000 pairs, of which at least 4000 pairs on main island; no evidence of decline in numbers. Although this species is very numerous within its extremely small range, and is thought not currently to be declining, the possible arrival of invasive species could rapidly result in steep decline in its numbers, potentially leading to extinction within a short period. With arrival of several motorized boats on Tristan, Nightingale I has been visited more frequently by other islanders, increasing risk of accidental introduction of mammalian predators such as rats and mice (Muridae) and other invasive species.
Bibliography. Abbott (1978), Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Collar & Stuart (1985), Elliott (1957), Hagen (1952), Lack (1947), Lowe (1923), Rand (1955), Richardson (1984), Ryan (2007, 2008), Ryan & Moloney (2002), Ryan *et al.* (2007), Shirihai (2002), Stattersfield & Capper (2000), Wilkins (1923).

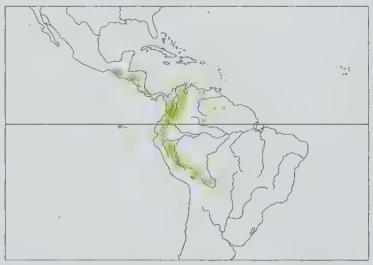
190. **Wilkins's Finch**

Nesospiza wilkinsi

French: Nésospize de Wilkins **German**: Wilkinsammerfink **Spanish**: Yal de Wilkins
Other common names: Grosbeak Bunting, Big-billed Finch/Bunting; Tristan Bunting/Finch (when treated as conspecific with *N. acunhae* and/or *N. questi*)

Taxonomy. *Nesospiza wilkinsi* P. R. Lowe, 1923, Nightingale Island, Tristan da Cunha Group.
Genus is closest to Neotropical finches, distant from Old World *Emberiza*. Genus confined to Tristan da Cunha island group, where it has undergone an adaptive radiation. This species usually considered conspecific with large-billed race (*dunnei*) of *N. acunhae*, but genetic evidence suggests independent evolution on each island. Cytochrome *b* sequence of present species appears identical to that of *N. questi*, but the two are highly distinct in terms of morphology and behave as separate species, with distinct vocal systems and no evidence of hybridization between them. Monotypic.
Distribution. Nightingale I, in S Atlantic.
Descriptive notes. 20–22 cm; 41–53 g. A large, robust finch with heavy, deep-based bill. Male is olive-green above and below, with yellowish supercilium, throat and upper breast; lores and area around eye grey; iris dark brown; bill slate-grey, whitish base of lower mandible; legs grey-brown. Distinguished from *N. questi* mainly by much greater size and much larger bill, on average almost twice the bill depth and mass of latter. Female is on average slightly smaller than male, also duller and slightly more streaked. Juvenile and immature resemble female, but buffy brown and more heavily streaked. Voice. Male song "whut-prreu whut-prreu...", distinctly deeper and slower than that of *N. questi*; female has subdued, querulous whistle, lower-pitched than that of female *N. questi*. Both sexes give a chipping contact call, also alarm call when skua (*Catharacta*) appears.
Habitat. Territorial adults occupy areas with *Phylica arborea* trees, also foraging in surrounding tussock grassland. Immatures may wander more widely.

Food and Feeding. Diet consists mainly of *Phylica* fruit and seeds; also includes small invertebrates. Clambers around in canopy of *Phylica* trees, crushing woody fruits to obtain large seeds; gleans invertebrates among *Spartina* tussock grassland and on the ground under *Phylica* copses.
Breeding. Little known. Egg-laying recorded Nov–Jan, but adults territorial at least Sept–Mar. Clutch 1–2 eggs, light blue, finely speckled dark brown. No other information.
Movements. Resident; ringed individuals recovered less than 200 m from original site after 8 years.
Status and Conservation. ENDANGERED. Restricted-range species: present in Tristan Islands EBA. Uncommon; has tiny breeding range, probably no more than 2 km². Global population extremely small, at most 100 pairs on Nightingale I; not recorded on offshore islets. Considered unlikely that population was ever much larger than it is now, and was probably adversely affected historically by cutting of *Phylica* wood for fuel, a practice which has now largely ceased. Although population currently appears stable, it is under constant threat from possible arrival of invasive species. With arrival of several motorized boats on Tristan, islanders from elsewhere visit Nightingale, and risk of accidental introduction of mammalian predators is thus permanent. A further potential threat is accidental introduction of certain invertebrates or pathogens which could alter food sources or reduce seed-set of *Phylica*; a black fungus-like growth has previously been transported from Tristan to Inaccessible I and, although there is currently no evidence of its presence on Nightingale, the risk remains. Islanders visiting Nightingale may cut *Phylicus* for fuel, and habitat potentially threatened also by catastrophic weather events. Invasive New Zealand flax (*Phormium tenax*) has been removed from the island.
Bibliography. Abbott (1978), Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Collar & Stuart (1985), Elliott (1957), Hagen (1952), Lack (1947), Lowe (1923), McCarthy (2006), Rand (1955), Richardson (1984), Ryan (2007, 2008), Ryan & Moloney (2002), Ryan *et al.* (2007), Shirihai (2002), Stattersfield & Capper (2000).



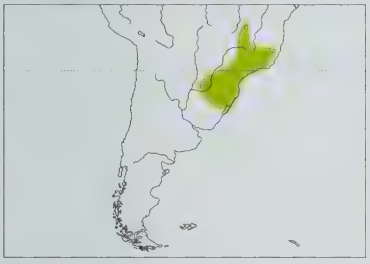
Genus *HAPLOSPIZA* Cabanis, 1851

191. **Slaty Finch**

Haplospiza rustica

French: Haplospize ardoisé **German**: Schieferämmerling **Spanish**: Yal Pizarroso

Taxonomy. *Phrygilus rusticus* Tschudi, 1844, Peru.
Molecular data suggest that this genus is part of a clade which includes also *Catamenia*, as well as *Phrygilus unicolor* and *Phrygilus plebejus* (but not others of that genus); in particular, a relationship between present genus and *Phrygilus unicolor* was suggested by early authors on basis of similarities in plumage and structure; molecular data indicate also that *Acanthidops* is related to present genus. This species probably forms a superspecies with *H. unicolor*. Middle American race *uniformis*, larger-billed than Neotropical ones, may deserve study to assess possibility that it represents a distinct species. Proposed race *barrilesensis*, described from W Panama (Barilles, in Chiriquí) on basis of purportedly smaller size than *uniformis*, is treated as a synonym of latter, as supposed differences based on very small samples. Three subspecies recognized.
Subspecies and Distribution.
H. r. uniformis P. L. Sclater & Salvin, 1873 – SE Mexico (S Chiapas; formerly also C Veracruz) and highlands of Guatemala, Honduras, N El Salvador and NW Nicaragua; also highlands of NC Costa Rica and extreme W Panama.
H. r. rustica (Tschudi, 1844) – N & W Venezuela S in Andes, including all three ranges in Colombia, to C Bolivia.
H. r. arcana (Wetmore & Phelps, Jr, 1949) – tepuis of S Venezuela.



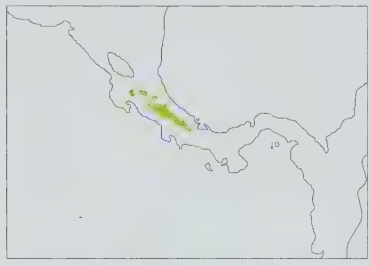
Descriptive notes. 12·5 cm; average 15·5 g. A slim finch with long, pointed bill and proportionately long, yet rounded, wing. Male nominate race is mostly plain lead-grey, paler on belly and vent; upperwing blackish with grey edging; tail blackish with grey edging; iris brown; bill blackish; legs dull brownish to blackish. Differs from similar *H. unicolor* mainly in noticeably longer bill, also some minor plumage differences. Female is dull brownish above, obscurely streaked, wing and tail dusky with brown edging throughout, off-white with yellowish tint below, olive-streaked on breast; bill dusky, distinguished from similar female of *Volatinia jacarina* by larger size, longer and more triangular bill, and more thickset body. Immature male is similar to adult, but wings have brown cast and upperwing-coverts edged brownish. Races differ subtly in darkness of plumage and in bill structure: *arcana* is distinctly darker, more blackish above, than nominate; *uniformis* has thicker and wider bill than others. Voice. Song, from perch, sometimes in flight (then shorter and less complex), high-pitched and sputtering in nature, aptly described as "sizzling". Shorter song 1–2 seconds long, a quick series of high-pitched trills and buzzes, "ti-ti-ti tswee-tswotit-dzzzz", sometimes reminiscent of song of Bananaquit (*Coereba flaveola*). Longer songs more than 3 seconds in duration, quicker and jumbled in nature. N race (*uniformis*) gives much more insect-like song dominated by high-pitched buzz, "tzzzzzzz-sitis-tzzz" or "tzi-tzeeeeeeeee". In one study involving ten males in Costa Rica, three song types identified; songs differed in length, also in type of sibilant note incorporated in the trill and where in trill it was inserted; a more complex and longer flight song was also identified. Call a high "tseep".
Habitat. Humid highland-forest edge where *Chusquea* bamboo present. A *Chusquea* specialist. Also forages in open grassy areas adjacent to highland forest. At 1200–3000 in Mexico and Central America; 1500–3500 m in Andes.
Food and Feeding. Seeds. Forages for bamboo seeds in undergrowth, on ground or near ground; at other times may forage for grass seeds in open areas at edge of forest. During non-breeding periods forms small flocks of up to 20 individuals.

Breeding. Little known. Season entirely dependent on the seeding of bamboo, which appears to be seemingly random in timing; egg dates Apr in Costa Rica and Sept in Ecuador. Nest globular with side entrance in Costa Rica, more open-topped in Ecuador (sample too small to determine if this a genuine geographical difference); one nest was placed 1·5 m above ground on fern-festooned bank next to a mule trail, contained 3 or 4 unspotted white eggs. No other information.
Movements. Irruptive, with local concentrations when *Chusquea* bamboo flowers and seeds; no detailed information on movements.
Status and Conservation. Not globally threatened. Generally uncommon to rare throughout its wide range, but becomes locally common where bamboo is seeding en masse. This species' irruptive behaviour, coupled with its preferred highland habitat, makes it very difficult adequately to assess populations, and in particular if its numbers have declined owing to the cutting of montane forests. As its needs are so specific, and as an adequate supply of seeding bamboo is possible only with huge tracts holding bamboo within them, this species would appear to be susceptible to population declines from even patchy and local habitat loss.
Bibliography. Armani (1985), Barajas *et al.* (1994), Garrigues & Dean (2007), Howell & Webb (1995), Martínez-Sánchez (1989), Miller & Moore (1954), Restall *et al.* (2006), Ridgely & Tudor (1989), Ríos-Uzcategui (1997), Sánchez (2005), Schulenberg *et al.* (2007), Stiles & Hespenheide (1972), Ugalde & Torres (2006), Willard *et al.* (1991).

192. **Uniform Finch**
Haplospiza unicolor

French: Haplospize unicolore **German**: Einfarbämmerling **Spanish**: Yal Unicolor

Taxonomy. *Haplospiza unicolor* Cabanis, 1851, Rio Grande do Sul, Brazil.
Molecular data suggest that this genus is part of a clade which includes also *Catamenia*, as well as *Phrygilus unicolor* and *Phrygilus plebejus* (but not others of that genus); in particular, a relationship between present genus and *Phrygilus unicolor* was suggested by early authors on basis of similarities in plumage and structure; molecular data indicate also that *Acanthidops* is related to present genus. This species probably forms a superspecies with *H. rustica*. Monotypic.
Distribution. E Paraguay, NE Argentina (Misiones) and SE Brazil (S Minas Gerais and S Espírito Santo S to Rio Grande do Sul).



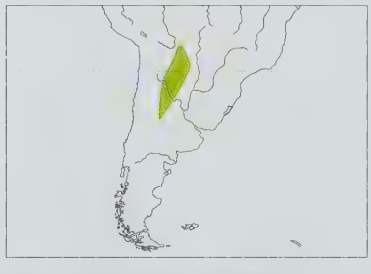
Descriptive notes. 12·5 cm; 14–17·5 g. A slim finch with well-proportioned conical bill. Male is almost entirely blue-grey and unstreaked, paler on belly and vent; upperwing blackish with blue-grey edging; tail blackish with blue-grey edging; iris dark brown; bill black; legs olivaceous to very dark pink. Differs from similar *H. rustica* mainly in noticeably shorter bill, some minor plumage differences; from *Tiaris fuliginosus* in larger size and longer and more pointed bill. Female is olive and obscurely streaked above, wings and tail dusky with olive edgings, off-white with yellowish tint below, breast olive-streaked, vent and undertail-coverts whitish with brown streaks; bill dusky with yellowish base of lower mandible, legs blackish. Immature male resembles adult, but duller and paler in body plumage, with paler bill and slightly yellowish base of lower mandible. Voice. Song high-pitched and buzzy, and short, lasting from half-second to nearly a full second, beginning explosively and ending with buzzy noise or high-pitched trill (sounding as if spat out), at times reminiscent of songs of *Volatinia jacarina*, "Pst-ts-tswaeeee" or "Pst-tsweee-bzzzzzz". Also performs long song, a continuous jumble of high-pitched buzzes and short notes lasting 4–8 seconds. May sing during short flights.
Habitat. Humid forest borders and undergrowth where abundant bamboo (*Guadua* and *Chusquea*). To 1400 m.
Food and Feeding. Seeds of bamboo, appearing to prefer *Guadua*; also grass seeds and insects. Forages near and on ground; at times also higher.
Breeding. Timing unclear, perhaps synchronized with bamboo flowering and seeding, specifically with the seeding of *Guadua* species; in Paraguay males sang throughout Mar–Apr during an irruption, suggesting possible breeding activity; in Brazil (Rio Grande do Sul) males with active gonads in Feb. In aerial song display, makes short fluttering flights, with legs dangling, between two branches a few metres above ground. No other information.
Movements. Irruptive, moving to areas of flowering and seeding bamboo.
Status and Conservation. Not globally threatened. Uncommon to rare throughout its range; becomes locally common where bamboo is seeding en masse. This species' irruptive nature and its preferred habitat make reliable assessment of populations very difficult, and determination of any decline in numbers owing to cutting of forests almost impossible. As its needs are so specific, and as an adequate supply of seeding bamboo is possible only with huge tracts that contain bamboo within them, this species would appear to be susceptible to population declines from even patchy and local habitat loss.
Bibliography. de Andrade & de Andrade (1997), Areta *et al.* (2009), Armani (1985), Olmos (1996), Ridgely & Tudor (1989), Sick (1993), Smith (2008).

Genus *ACANTHIDOPS* Ridgway, 1882

193. **Peg-billed Finch**
Acanthidops bairdi

French: Bec-en-cheville gris **German**: Spitzschnabelämmerling **Spanish**: Yal Costarricense

Taxonomy. *Acanthidops bairdi* Ridgway, 1882, Volcán de Irazú, Costa Rica.
Molecular evidence and bill shape suggest that genus is part of a group that contains also *Diglossa* and *Xenodacnis* (both currently placed in family Thraupidae) and *Catamenia*, but plumage details suggest that it may be closest to *Haplospiza*. Species name often misspelt "*bairdii*". Monotypic.
Distribution. Highlands of Costa Rica (S from Cordillera Guanacaste) and W Panama (W Chiriquí).
Descriptive notes. 13 cm; 16 g. A small finch with peculiar bill shape, very narrow, in profile long and fine, yet thicker-based, looking constricted a third of the way from base, and long and thin for rest of length. Male is entirely dark grey and unstreaked, underparts only slightly paler than upperparts, on some belly paler and rear flanks olive-toned, others darker grey throughout; iris dark brown; upper mandible blackish, lower mandible often yellowish; legs dull pinkish. Female is brownish-olive above, obscurely streaked from crown to back, face greyish with pale buffy supercilium; upperwing-coverts tipped cinnamon to whitish (creating two pale wingbars), tertials and flight-feathers edged chestnut, tail brownish; rich buff below, obscurely streaked on throat, breast and flanks, with lower flanks to undertail-coverts rich olive-russet; bare parts much as for male. Juvenile resembles female, but wingbars paler, more buffish, also paler below. Voice. Song 3–4 rapid-fire high-pitched notes followed by almost electric buzz, "t-t-t-tzééééwww". Call a high-pitched "tsip".



Habitat. Edges and more open areas of highland forest and cloudforest, particularly if bamboo thickets present; forages also in pastures adjacent to forest. At 1500–3100 m.
Food and Feeding. Food primarily arthropods, both insects and spiders (Araneae); also seeds, particularly of bamboo, as well as other grasses (e.g. *Trisetum*), and takes nectar at times. In forest forages along limbs in manner similar to that of a foliage-gleaner (Furnariidae), also in low shrubbery and on ground; in grassy areas adjacent to forest will sally up to grass stalks and bring them down in order to feed on seeds. Consumes larger berries in curious manner, piercing them with bill and then transporting them to horizontal branch, where it squeezes berry to obtain the juice, and then discards the skin. Forages in pairs, singly and in small flocks.
Breeding. Season Mar–Jun. Nest built by female, a bulky, compact cup of plant material, one consisted mainly of leafy liverworts, moss and very small amounts of a fruticose lichen, interior layers of fern rhizomes, straw and *Thuidium* moss, placed c. 2·25 m up in centre of *Vaccinium* shrub. Clutch typically 4 eggs, greenish-blue with very small spots of burnt amber, these concentrated at broad end and forming a wreath; incubation by female, period 12–14 days. No other information.
Movements. Resident; moves locally to take advantage of periodic seeding of bamboo.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Generally uncommon to rare throughout its range; becomes locally common where bamboo is seeding en masse. Not a strict bamboo specialist, but the only records from Panama were during a bamboo seeding period.
Bibliography. Armani (1985), Garrigues & Dean (2007), Sánchez-Pérez & Hernández-Esquivel (1990), Sassi (1939), Stiles & Hespenheide (1972), Stiles & Skutch (1989), Wetmore *et al.* (1984).

Genus *LOPHOSPINGUS* Cabanis, 1878

194. **Black-crested Finch**
Lophospingus pusillus

French: Lophospingue à huppe noire **Spanish**: Soldadito Común
German: Schwarzhauben-Zwergkardinal

Taxonomy. *Gubernatrix pusilla* Burmeister, 1860, Tucumán, Argentina.
Molecular data indicate that genus may be sister to White-banded Tanager (*Neothraupis fasciata*), and that these in turn are part of a clade which includes also *Diuca diuca*, *Paroaria* cardinals, Magpie Tanager (*Cissopis leverianus*) and *Schistochlamys* tanagers; this would suggest that all should be included in the tanager family (Thraupidae). Monotypic.
Distribution. S Bolivia (S Santa Cruz, E Chuquisaca and E Tarija) and W Paraguay S to C Argentina (Salta and Formosa S to E San Juan, N San Luis and W Córdoba).

Descriptive notes. 14 cm; 14–20·5 g. A relatively slim-looking finch with long tail, bill triangular and robust for size of the bird, and head obviously crested. Male has striking, bold black-and-white head pattern, with black forehead to crown, including pointed crest, broad black mask from lores through eye and widening towards side of neck, small white lower eye-crescent, white moustachial and malar region broadening towards rear, contrasting black throat; hindneck and body grey, darker above than below, undertail-coverts white; wing and tail dark grey with paler grey edging, outer rectrices edged white on outer web; iris dark brown; bill dull pinkish-yellow with black culmen (appears bicoloured); legs dusky. Female is similar to male in pattern, but black areas of face replaced with brown, throat pale with darker malar stripe; upperparts brownish, median and lesser upperwing-coverts whitish, often greater coverts distinctly grey (appearing as greyish wingpanel on perched bird); underparts greyish, obscurely streaked; bare parts much as for male. Immature is like female, but browner above and more noticeably streaked below. Voice. Flocks may give jumbled busy set of calls, reminiscent of a flock of Budgerigars (*Melopsittacus undulatus*). Call a nasal "chnip"; excitement calls a series of nasal notes given quickly as a chatter.
Habitat. Open *chaco* woodland and forest edge, including grassy pastures and roadsides adjacent to woodland. Usually below 1000 m; to 2000 m in Bolivia.
Food and Feeding. Little information. Feeds on seeds and arthropods. Forages on ground, often in pairs or small flocks.
Breeding. Nest built by male, a cup-shaped structure of vegetable fibres and lichens tangled with spider webs, and lined with rootlets, animal hair and some feathers; often placed in large cactus. Clutch 3 eggs, pale bluish-green with brown spots. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally uncommon and local; reasonably abundant in some places. No known threats.
Bibliography. Armani (1985), Blendinger & Ojeda (2001), Bosche (1988), Canevari *et al.* (1991), Klicka *et al.* (2007), Leitch (1970), Ridgely & Tudor (1989), Roder (1991).

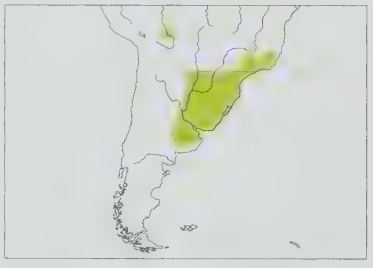
195. **Grey-crested Finch**

Lophospingus griseocristatus

French: Lophospingue gris **German**: Grauzwergkardinal **Spanish**: Soldadito Gris

Taxonomy. *Emberiza griseo-cristata* d'Orbigny and Lafresnaye, 1837, Valle Grande, Santa Cruz, Bolivia.
Molecular data indicate that genus may be sister to White-banded Tanager (*Neothraupis fasciata*), and that these in turn are part of a clade which includes also *Diuca diuca*, *Paroaria* cardinals, Magpie Tanager (*Cissopis leverianus*) and *Schistochlamys* tanagers; this would suggest that all should be included in the tanager family (Thraupidae). This species was formerly given its own genus, *Schistospiza*, but exhibits obvious plumage similarities to, and no structural differences from, present genus. Monotypic.
Distribution. W & S Bolivia (E La Paz, E & S through C Cochabamba, W Santa Cruz, W Chuquisaca and W Tarija) and extreme N Argentina (E Jujuy and N Salta).

Descriptive notes. 14 cm; 13·1–20·2 g. Pale grey to brownish emberizid with relatively deep-based bill, and a crest usually kept lowered. Head is plain grey, with darker crest; upperparts grey, olive wash on back, more blue-grey on rump; upperwing brownish, grey upperwing-coverts and grey edging of flight-feathers (making folded wings appear largely greyish); tail brownish-grey, white tips on inner webs of outer three pairs of rectrices (creating large white tail corners in flight); throat, breast and flanks pale grey, contrasting whitish belly, vent and undertail-coverts; iris dark; upper mandible dark, lower mandible largely yellow to pinkish with dark tip; legs dusky. Sexes alike. Juvenile is much more brownish than adult, with short crest, pale buff supercilium, off-white throat, and two narrow buffy wingbars. Voice. Song consists of 3–4 different elements given in bouts of average of six elements, quality of song throaty and gaps between elements nearly equivalent to lengths of latter, a bout lasting c. 5 seconds, "pwee switoo pizitoo switoo pizitoo switoo pizitoo"; resembles song of *Diuca diuca*, but sharper and with throaty-sounding elements. Another song type is longer and continuous, with longer gaps between elements, thus slower more relaxed tempo.
Habitat. Desert and near-desert habitats in dry intermontane valleys, also dry scrub with taller cactus and mesquite (*Prosopis*). Likes, or perhaps requires, open areas of bare earth near vegetation, where often forages; also uses roadsides and agricultural fields adjacent to xeric scrub. At 1000–3100 m.
Food and Feeding. Diet not studied; appears to be a mix of seeds and arthropods. Forages on ground in small flocks.
Breeding. Little known. In Bolivia, juveniles observed in Dec and Jun (Cochabamba) and in Apr (Santa Cruz). No other information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally common in Bolivia; much rarer in Argentina. A poorly known species.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Klicka *et al.* (2007), Ridgely & Tudor (1989).



Genus *DONACOSPIZA* Cabanis, 1851

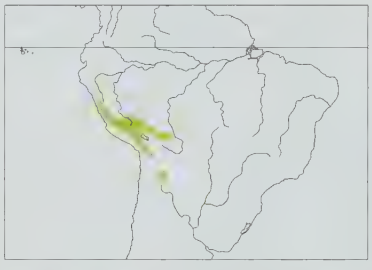
196. **Long-tailed Reed-finch**

Donacospiza albifrons

French: Donacospize des marais **German**: Riedammerfink **Spanish**: Cachilo Canela

Taxonomy. *Sylvia albifrons* Vieillot, 1817, Paraguay.
Song and colour pattern suggest that this species may be closely related to *Poospiza*. Monotypic.
Distribution. Bolivia (Beni); SE Paraguay and SE Brazil (S from S Paraná, S São Paulo, S Minas Gerais and W Rio de Janeiro) S to NE Argentina (Misiones, Corrientes, E Formosa and E Chaco S to E Córdoba and NE Buenos Aires) and Uruguay.

Descriptive notes. 15 cm; 14–16·5 g. A small and slim finch with long tail, short and rounded wings, and relatively small and well-pointed bill; tail feathers pointed (and often frayed to even narrower points), inner two pairs longer than outer rectrices, shape not dissimilar to that of a *Synalaxis* spinetail. Male has grey cap and face, well-defined whitish-cinnamon supercilium that tapers behind eye, narrow buffy lower eye-crescent; dark eyeline through grey face (giving a rather serious-looking expression); grey of crown blends into tawny-brown on back, which streaked blackish, lower back and rump brighter tawny and much less streaked; tail feathers brown, edged tawny; upperwing brown with tawny edgings, lesser upperwing-coverts blue-grey (often hidden); throat and underparts pale tawny, slightly paler or approaching white on chin and areas bordering grey face, whitish or pale buff on vent and undertail-coverts; iris dark; bill black; legs dusky pink. Female is very like male, perhaps slightly less colourful, but much overlap in appearance. Immature is similar to adult, but tail shorter and not so pointed, face yellowish with darker crown and mask, duller in colour and more heavily streaked above, wing feathers crisply edged buff, underparts yellowish and streaked on breast. Voice. Song a pleasant series of two or three elements repeated, e.g. "twee-cha twee-cha twee-cha..." or "twee-ta wheet-cha twee-ta wheet-cha...", reminiscent of songs of *Poospiza*; shorter version given in aerial display. When particularly excited during territorial defence (as is often the case during playback experiments), both adults respond with a chattering and jumbled duet song. Calls include nasal note, often doubled, "thup-thup"; also a series of "tiip" notes e.g. "tiip tiip tiip tiip".
Habitat. Marshes and reedbeds with tall emergent vegetation (*Typha*, *Eryngium*, *Scirpus*, *Iris*), also wet tall-grass fields, and open shrubby areas near marshes or standing water; closely associated with water. To 900 m.
Food and Feeding. Primarily insects; will also take seeds. Forages by probing in emergent vegetation. Sometimes follows army ants (Formicidae). In pairs and family groups.
Breeding. Season Oct–Feb; juveniles seen in Jul in Bolivia. Performs short song flight, flying directly upwards a few metres, before gliding down to reeds while singing. Nest a semi-spherical structure created from soft dry grass, placed near or on ground on thick grass clump. Clutch 4 eggs, white with darker spotting on wide pole. Parasitization by Shiny Cowbird (*Molothrus bonariensis*) recorded. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common where its tall-grass marsh habitat exists. Main threat is the draining of wetlands.
Bibliography. Armani (1985), Azpiroz (2003a), Belton (1985), Di Giacomo & Aguilar (1987), Di Giacomo & Di Giacomo (2006), Friedmann *et al.* (1977), Maillard *et al.* (2008), de la Peña (1989), Ridgely & Tudor (1989), Schmitt & Schmitt (1987), Sick (1993).



Genus *DIUCA* Reichenbach, 1850

197. **White-winged Diuca-finch**

Diuca speculifera

French: Diuca leucoptère **German**: Spiegelammer **Spanish**: Diuca Aliblanca

Taxonomy. *Emberiza speculifera* d'Orbigny and Lafresnaye, 1837, Bolivia.
Previously thought to form a superspecies with *D. diuca*, but aspects of morphology, voice and typically hopping (rather than walking) locomotion suggest that it is not close to that species; likely more closely related to *Phrygilus erythronotus* and *Phrygilus dorsalis*. Race *magnirostris* doubtfully distinct from nominate. Two subspecies provisionally recognized.
Subspecies and Distribution.
D. s. magnirostris Carriker, 1935 – highlands of C Peru (Ancash to Junín and Huancavelica).
D. s. speculifera (d'Orbigny & Lafresnaye, 1837) – Andes of SC & S Peru (S from Arequipa, Cuzco and Puno; probably also this race in Ayacucho and Apurímac), N Chile (Arica–Parinacota and Tarapacá), W Bolivia (La Paz, Cochabamba and NW Oruro), and NW Argentina (Jujuy).

Descriptive notes. 17·5–19 cm. A large finch with relatively long, stout bill, thickset body, and very long wings; bold white patches in plumage. Nominate race has head mostly grey, blackish on lores, with noticeable white elongate patch below eye; upperparts plain grey; tail blackish, outer rectrix with bold white edge, other feathers with greyish-white edges; upperwing-coverts entirely grey, flight-feathers blackish, large white patch at base of outer primaries (unmistakable in flight), secondaries and tertials edged greyish; grey of face extends well down to side of throat, and borders clean white patch on throat down to edge of upper breast; breast otherwise grey, flanks grey, and belly to undertail-coverts white; iris dark; bill and legs black. Sexes alike. Juvenile resembles adult, but brownish above, with buffy throat. Race *magnirostris* is very like nominate, but bill averages longer. Voice. Possible song a very simple repetition of various short notes with wide intervals between elements, "tsweep—weep—twoop—tsweep—", notes so widely separated as to sound barely different from a bird giving call notes, but difference is that short elements are varied (not a single call note repeated); more study needed in order to determine if this simple vocalization is indeed song. Calls a high, thin "tseep" and a rising "pheep".
Habitat. Breeds in alpine rocky crags and even glaciers, foraging in *bofedal* wetlands ("cushion bogs"); will roost in crevasses within glaciers. Also in *puna* bunch-grass, but prefers to forage in moister sites, particularly *bofedales* with cushion plants (*Distichlis*, *Plantago rigida*). At 4000–5500 m. Possibly breeds at higher elevation than any other passerine in the Americas, nesting recorded to 5400 m.
Food and Feeding. Diet not studied; likely a mix of arthropods and seeds. Forages on ground, in pairs. Forages with body close to ground, often crouching such that legs difficult to see.
Breeding. Season begins at end of wet season, in Apr, and continues to Aug. Nest a bulky structure of grass and twigs, with well-made, deep cup near centre, lined with finer grasses and feathers, placed usually in rock crevice, sometimes on glacier (the only avian species currently known to use high-elevation glaciers as substrate for nest). Clutch 2–3 eggs, pale greenish with darker purplish-brown spots. No other information.
Movements. Sedentary. During intense snow storms may temporarily descend to lower elevations, returning upwards once storm has passed.
Status and Conservation. Not globally threatened. Reasonably common throughout its range. Because it is restricted to the highest Altiplano region, global warming may restrict its habitat in the future; populations should be monitored.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hardy & Hardy (2008), Jaramillo (2003), Ridgely & Tudor (1989).

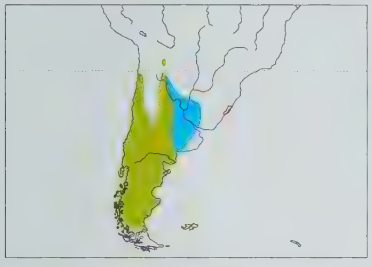
198. **Common Diuca-finch**

Diuca diuca

French: Diuca gris **German**: Blausteißammer **Spanish**: Diuca Común
Other common names: Lesser Diuca-finch (*minor*)

Taxonomy. *Fringilla Diuca* Molina, 1782, Chile.
Previously thought to form a superspecies with *D. speculifera*, but aspects of morphology, voice and typically walking (rather than hopping) locomotion suggest that it is not close to that species. Recent molecular data indicate that present species is the earliest offshoot in a clade which includes *Lophospingus*, White-banded Tanager (*Neothraupis fasciata*), *Paroaria* cardinals, Magpie Tanager

(*Cissopis leverianus*) and *Schistochlamys* tanagers; this would suggest that all should be included in the tanager family (Thraupidae). Four subspecies recognized.



Subspecies and Distribution.

D. d. crassirostris Hellmayr, 1932 – NC Chile (Antofagasta S to Coquimbo), extreme S Bolivia (SE Potosí) and N Argentina (Jujuy and Salta S to La Rioja).

D. d. diuca (Molina, 1782) – C & SC Chile (Coquimbo S to Aysén) and adjacent Argentina (Mendoza S to Santa Cruz).

D. d. minor Bonaparte, 1850 – C & S Argentina (Córdoba, San Luis and S Buenos Aires S through E Mendoza to Santa Cruz) and S Chile (N Magallanes); non-breeding also N to NE Argentina (Tucumán and Entre Ríos), S Brazil (W Rio Grande do Sul) and Uruguay.

D. d. chiloensis R. A. Philippi [Bañados] & Peña, 1964 – Chiloé I (SC Chile).

Descriptive notes. 16–18 cm; 25–41 g. A medium-sized finch with thickset body, and stout bill with rounded culmen. Male nominate race has head mostly dark grey, slightly darker on lores, narrow white eye-crescent below eye; upperparts plain dark grey, back washed olive, lower back and rump blue-grey; tail brownish-grey, inner webs of outer three feather pairs with large white tips (creating large white tail corners in flight); upperwing-coverts grey, darker on centres and paler on edges, flight-feathers blackish with grey edging; throat and malar area extensively white, cleanly demarcated at lower border from dark grey breastband; grey of breast extends to flanks and contrasts with white belly and vent, white of belly extends upwards in inverted V-shape into grey of breast, flanks often with buffy tinge, becoming rusty behind legs, undertail-coverts whitish with rusty wash; iris brown; bill blackish, blue-grey base of lower mandible; legs brownish-grey to blackish. Female is very like male, but tinged olive or brownish, also rusty tone of flanks paler and less extensive. Immature is dull and brownish, but with similar pattern to that of female, and vent buff (not rufous). Races differ mainly in size or in saturation of plumage colour: *crassirostris* is largest, has proportionately large and thick bill (noticeable in the field), also outer web of outermost tail feather wholly white; *minor* is smallest, and tinged brownish above; *chiloensis* is smaller than nominate, plumage coloration more saturated. Voice. Song musical and pleasant, 4–5 notes delivered lazily, with final element accented, "tiuup tween chwuup twééip", reminiscent of song of Golden-billed Saltator (*Saltator aurantiirostris*). Call a sweet "tweep".

Habitat. Occupies wide diversity of open or semi-open and edge habitats, including agricultural areas, rural towns, city parks, pastures, *matorral* scrub, desert scrub, dry forest edge and shrubland within Monte Desert (Argentina), and temperate-forest edge. Sea-level to 2500 m.

Food and Feeding. Diet seeds, particularly grass seeds (80% of food in stomach samples from Argentina), and invertebrates, proportions varying depending on season. Seeds important in winter (in winter in Argentina, densities of this species correlated with seed densities in the environment); in spring and summer will take more arthropods. Forages mostly on ground, where it walks, rather than hops, with gait like that of a quail (Phasianidae); tendency to do some foraging on low shrubs, rather than strictly on ground, in spring and summer. In pairs and family groups; also small flocks in non-breeding season.

Breeding. Season Sept–Feb in Chile and Nov–Jan in NC Argentina; up to three broods in a season in C & S Chile, single-brooded in Monte Desert of Argentina. Nest an open cup made from dry grass and vegetable fibres, lined with soft vegetation or wool, placed at various heights in bush or tree, in C Chile either hidden in thornless tree with dense foliage or sited conspicuously in thorny tree with low leaf density (latter nests also lined with thorny twigs); in Argentina placed in platform of old, abandoned spiny nest of furnariid, e.g. Short-billed Canastero (*Asthenes baeri*) or Brown Cachalote (*Pseudoseisura lophotes*), or of Monk Parakeet (*Myiopsitta monachus*). Clutch 2–4 eggs, most commonly 3, pale green, densely spotted and blotched brown. Nests frequently parasitized by Shiny Cowbird (*Molothrus bonariensis*).

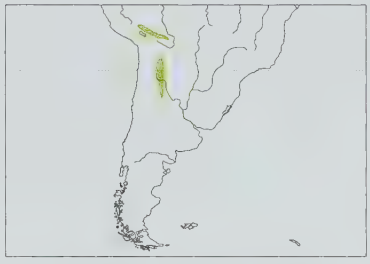
Movements. Mostly resident. S Argentine race (*minor*) appears to be at least partially migratory; recorded from NE Argentina, Uruguay and S Brazil only in winter.

Status and Conservation. Not globally threatened. Common to locally abundant in much of Chile and W & S Argentina. Subjective observations in SC Chile suggest that this species is not as common as it was several decades ago; speculated that more intensive agricultural practices have perhaps caused a decline. Introduced House Sparrow (*Passer domesticus*) has been blamed locally for lowering numbers of this species near villages and in urban areas.

Bibliography. Armani (1985), Bertonatti & Guerra (1997), Blendinger (2005a, 2005b), Blendinger & Ojeda (2001), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson & Goodall (1967), Klicka *et al.* (2007), Lazo (1996), Lazo & Anabalón (1991), Marone *et al.* (1997), Marone, de Casenave, Milesi & Cueto (2008), McCarthy (2006), Mezquida (2003), Navas & Bó (1988b), Ridgely & Tudor (1989).

Genus *IDIOPSAR* Cassin, 1867

199. **Short-tailed Finch**



Idiopsar brachyurus

French: Idiopsar à queue courte **German**: Kurzschwanzammer **Spanish**: Yal Colicorto
Other common names: Andean Boulder-finch, Short-tailed Diuca-finch

Taxonomy. *Idiopsar brachyurus* Cassin, 1867, La Paz, Bolivia.
Monotypic.

Distribution. S Peru (S Cuzco and Puno) S through highlands of Bolivia (La Paz, W Cochabamba, E Oruro, E Potosí and W Tarija) to NW Argentina (Jujuy, highlands of Salta, Tucumán and Catamarca).

Descriptive notes. 18–18·5 cm; one male 43 g. A large and thickset finch with very long and stout-based, spike-like bill; big body can make tail appear somewhat short. Male has head grey, fine whitish streaking below eye; upperparts all plain lead-grey; wing and tail greyish, similar in colour to upperparts, but wing paler, outer edge of outer rectrix white; paler grey below, particularly on throat and central breast, contrasting with darker sides, with belly and vent whitish, undertail-coverts grey; iris reddish-brown; bill horn-grey, paler lower mandible; legs dull pinkish. Differs from similarly plumaged *Phrygilus unicolor* in large size, proportionately large body and relatively

short tail, and very long and peculiar bill. Female is similar to male, but with browner tone. Juvenile is like female, but browner still, and obscurely streaked below, also grizzled grey on face, and has brown eye and yellowish base of lower mandible. Voice. Song a simple repetition of notes, "tseet tsu tsree tseet tsu tsree..." or "schrii su su schrii su su schrii su su". Call a high-pitched "ziht".

Habitat. A specialist of boulderfields and talus slopes comprised of larger rocks and boulders adjacent to *puna* grasslands. Generally not found away from rock piles or boulders, although in Argentina seen to use rock walls (*pircas*) in an Andean village and recorded also from boulder-strewn riverbanks adjacent to *Festuca* grassland; in Cuzco (Peru) also edge of *Polylepis* forest near grassland. At 4000–4600 m, rarely down to 3500 m.

Food and Feeding. No detailed information on diet; seen to feed on seeds, also on lichen on rocks. Study of diet important, as this species may be very particular in terms of food choices. Forages mostly on ground. In Peru, obtained seeds of *Gentianella aurantiaca* by digging around one spot (to depth of 2·7 cm) and looking for a seed, then extracting edible part, discarding seed sheath and breaking the seed before consuming it. Found alone and in pairs; also, flocks of up to six individuals observed. Has tendency to perch on a conspicuous rock with bill held pointing at upward angle, which makes bill often appear upturned.

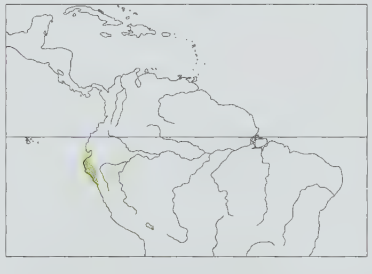
Breeding. Largely unknown. Males in breeding condition in Jan in Bolivia (La Paz); in Argentina female observed while inspecting crevices in adobe walls, perhaps looking for nesting site. No other information.

Movements. Sedentary, so far as is known.

Status and Conservation. Not globally threatened. Rare and/or local throughout much of its range; locally common in a few sites in Bolivia. Occurs in three protected areas In Bolivia: Carrasco National Park (Cochabamba) and Cordillera de Sama Biological Reserve and Tariquía National Reserve (Tarija).

Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Lloyd *et al.* (2005), Mazar Barnett, Clark *et al.* (1998), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Vuilleumier (1969a).

Genus *PIEZORINA* Lafresnaye, 1843



200. **Cinereous Finch**

Piezorina cinerea

French: Piézorhin cendré **German**: Grauämmerling **Spanish**: Yal Cinéreo

Taxonomy. *Guiraca cinerea* Lafresnaye, 1843, Galapagos Islands; error = coastal north-west Peru.
Genus name often spelt "*Piezorhina*", but this is an unjustified emendation; original spelling (where name applied as subgenus for present species) should stand. Monotypic.

Distribution. NW Peru from Tumbes S to La Libertad.

Descriptive notes. 16·5 cm. Distinctive, relatively large and thickset emberizid with peculiar large and thick, rounded-looking bill with strongly rounded culmen. Has head mostly pale grey, blackish mask from base of bill to forehead and lores, contrasting with pale bill; upperparts pale grey with very slight sandy wash, wings and tail similarly greyish; pale grey below, contrasting white throat, and whitish belly and vent; iris brown; bill and legs yellow. Sexes alike. Juvenile lacks dark face of adult, is pale sandy grey on upperparts, off-white below, with buffy breast and flanks, and bill and legs duller, more pinkish-yellow. Voice. Song a jerky series of rich, short squeaky phrases. Calls include "teep" and "tee-too", as well as a dry "tik-tik-tik".

Habitat. Occupies open, arid, sandy habitats with short shrubs and small and scattered trees; present up to 300 m.

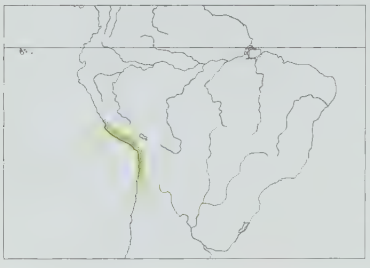
Food and Feeding. Seen to forage on the ground in singles and pairs. No other information.

Breeding. Eggs reported in May–Jun, the transitional period between rainy and dry seasons. Nest a well-built cup of yellowish plant fibres, secured by spider webs, with spider egg cases and shreds of dry yellow leaves attached to outside, tends to be placed on fork of branch of small tree. Clutch 2–3 eggs, pale blue with dense brownish markings. Heavily parasitized by Shiny Cowbird (*Molothrus bonariensis*); appears sometimes to build new lining on top of parasitized nest. No other information.

Movements. Generally sedentary. One record of vagrant in extreme S Ecuador (S Loja).

Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Common within its small range and limited habitat. Not well known; apparently no immediate threats.

Bibliography. Armani (1985), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Trollope (1993), Williams (1981a).



Genus *XENOSPINGUS* Cabanis, 1867

201. **Slender-billed Finch**

Xenospingus concolor

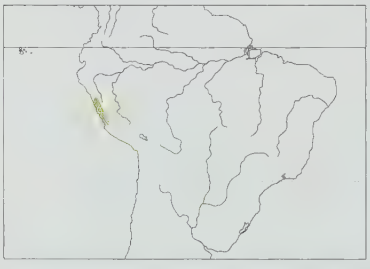
French: Xénospingue uniforme **German**: Feinschnabelämmerling **Spanish**: Yal Picofino

Taxonomy. *Sylvia concolor* d'Orbigny and Lafresnaye, 1837, Arica, Chile.
Monotypic.
Distribution. S Peru from S Lima (R Rímac) S to Tacna, and NW Chile S to N Antofagasta (R Loa).

Descriptive notes. 15–17 cm; 20–22 g. A very long and slim finch, with tail and bill long and slender, as is body, and legs proportionately long; bill distinctive in shape and very atypical, long and narrow with only slight curve of culmen, and rather straight gonys. Plumage is almost entirely slate-grey, slightly paler grey on underparts, becoming greyish-white on vent; black area on lores extending to lower forehead and chin; partial white eyering; wing and tail unmarked dark grey; iris deep brown; bill and legs deep yellow. Sexes alike. Juvenile and first-year immature lack black mask of adult, although they do show pale buffy eyering, are brownish-grey, brown wings with buff wingbars, paler buffish below, obscurely streaked on underparts, with bill and legs dusky; second-year resembles adult, but has brownish tone to back, sometimes faint streaking on breast, often a dark tip of yellow bill, wings greyish and lack wingbars, black mask still absent. Voice. Song choppy-sounding, delivered slowly (2 elements per second), a series of single whistles, each differing slightly in pitch from others, interspersed with harder "chup" notes, song lasting c. 4 seconds, "twee chup cheeuu truup chee tweet chup...". Calls include metallic "tzip", lower "cheep", and distinctive series of buzzy scolding notes, "chip-chip-chip-t'tzzzp".

Habitat. Desert valleys, where it prefers areas with dense riparian shrubbery adjacent to more open areas or grassy patches. In N Chile takes readily to olive (*Olea europaea*) plantations because of their size and density. In Peru, found in areas with continuous coverage of *Prosopis pallida*, *Tessaria integrifolia* and *Baccaris salicifolia*, as well as introduced olive groves and Chinese tamarisk (*Tamarix chinensis*); absent from valleys where native trees and shrubs completely eliminated. Occurs from sea-level up to 500 m in most areas, but in S portion of range up to 2500 m; vagrant up to 3500 m.
Food and Feeding. Mainly insects; seeds appear to form relatively unimportant part of diet; takes fruit on occasion. Foraging mostly in dense shrubbery. Gleans insects from foliage. Found in pairs and family groups.
Breeding. Season Dec–Jun in S Peru. Both members of pair present during nest-building, but apparently only female builds nest, a globular mass 11–13 cm in diameter, made from interwoven twigs, placed 1·5–2 m up in fork in riparian vegetation. No other information.
Movements. Sedentary; vagrant reported in Putre (Parinacota Province), in NE Chile.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common in Chilean part of range; less common and more local in Peru. No data on global population total, but appears to be fairly small, and habitat now fragmented. This species' habitat of river valleys is subject to heavy adverse impact through spread of agriculture and human habitations. In Chile, at least, it adapts well so long as some thick shrubbery is present near agricultural areas or settlements; towards end of 20th century colonized a new area in Antofagasta, having not been recorded in that province since mid-1940s. Has already suffered substantial loss and degradation of habitat in Peru, and is probably in slow decline there.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), González (1997), González & Hoegsaas (1998), González & La Torre-Cuadros (2001), Jaramillo (2003), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

PLATE 59 ➤



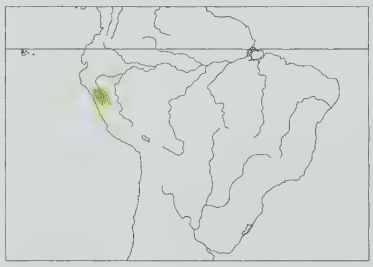
Genus *INCASPIZA* Ridgway, 1898

202. Great Inca-finch

Incaspiza pulchra

French: Chipiu remarquable **German**: Inkaammer **Spanish**: Incaspiza Alirrufo
Other common names: Great Inca-sparrow

Taxonomy. *Haemophila pulchra* P. L. Sclater, 1886, Matucana, upper River Rímac valley, about 8000 feet [c. 2440 m], Lima, Peru.
Forms a superspecies, and sometimes considered conspecific, with *I. personata* and *I. ortizi*. Monotypic.
Distribution. W slope of Andes (in Ancash and Lima), in W Peru.



Descriptive notes. 16·5 cm; 25·5–32 g. A rather long-tailed finch with slim, pointed bill. Has grey head, browner on crown and nape, with blackish lores, eyeline and narrow line over base of bill (not extending to forehead), narrow whitish-grey supercilium above this mask; upperparts brownish, scapulars rufous, lower back to uppertail-coverts dull brown; tail black with white outer edges; upperwing largely rufous, browner inner half of tertials, grey lesser upperwing-coverts (often hidden by body feathers or scapulars); mask connects with black on throat to upper breast, rest of breast grey, flanks buffy grey, belly and vent off-white; iris dark brown; bill and legs orange-yellow. Differs from *I. personata* in smaller size, browner back, with less black on face, more black on throat, and greyer breast. Sexes similar in pattern, the female browner on crown and somewhat duller. Immature is duller than adult, lacks black on face and throat, is streaked above and below, bill dull yellow with dark culmen, legs dull yellow. Voice. Song a series of high, thin whistles, "tsew tseee? tsew tswee?". Call a single "tsew" or "tsee"; also a short, quavering descending note, "tsee'le'le'le'le".
Habitat. Arid slopes and ravines with large cacti (of genus *Melocactus*) and/or ground bromeliads. At 1000–2700 m, mostly above 1500 m.
Food and Feeding. Feeds on fruits of *Melocactus* cacti. Forages on ground, with tail held cocked. Generally alone or in pairs; in non-breeding season in groups of up to seven individuals.
Breeding. Fledglings and juveniles seen between May and Jun. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian High Andes EBA. Uncommon and local; reported as common in Ancash. No known threats.
Bibliography. Armani (1985), Bond (1951a), Fjeldså & Krabbe (1990), González (2003), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

203. Rufous-backed Inca-finch

Incaspiza personata

French: Chipiu costumé **German**: Schwarzstirnammer **Spanish**: Incaspiza Dorsirrufo
Other common names: Rufous-backed Inca-sparrow

Taxonomy. *Haemophila personata* Salvin, 1895, near Cajamarca, 10,000 feet [c. 3050 m], Peru.
Forms a superspecies, and sometimes considered conspecific, with *I. pulchra* and *I. ortizi*. Monotypic.
Distribution. Upper Marañón Valley in S Cajamarca, E La Libertad, NE Ancash and W Huánuco, in NW Peru.
Descriptive notes. 16·5–18 cm; 29·5–33 g. A rather long-tailed finch with slim, pointed bill. Has grey head, browner on nape, with blackish mask fully surrounding bill, extending narrowly to forehead and below to most of throat;

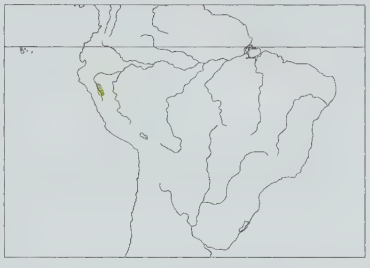
upperparts, including lower back to uppertail-coverts, rufous, greyer nearer tail; tail black with white outer edges; upperwing largely rufous, grey outer median and greater upperwing-coverts, browner inner half of tertials; lower throat and breast grey, flanks buffy grey, belly and vent off-white; iris brown; bill bright yellow; legs orange-yellow. Distinguished from *I. pulchra* mainly by larger size, more extensive black on face, wholly rufous upperparts lacking brown, paler underparts. Sexes alike. Immature is duller than adult, lacks black on face and throat, is streaked above and below, bill dull yellow with dark culmen, legs dull yellow. Voice. Song a weak and high "tisew-ti'tswéé?". Calls include high "tseet" notes.
Habitat. Inhabits dry mountain slopes with cacti and agave and with *Puya raimondii*; occurs at 2300–4000 m.
Food and Feeding. Little information on diet. Forages on ground, singly and in pairs.
Breeding. Males in breeding condition between late Mar and Jun, and fledglings found in May. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Marañón Valley EBA and Peruvian High Andes EBA. Uncommon. Not well known.
Bibliography. Armani (1985), Bond (1951a), Fjeldså & Krabbe (1990), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

204. Grey-winged Inca-finch

Incaspiza ortizi

French: Chipiu d'Ortiz **German**: Grauflügelammer **Spanish**: Incaspiza Aligrís
Other common names: Grey-winged Inca-sparrow

Taxonomy. *Incaspiza ortizi* J. T. Zimmer, 1952, near La Esperanza, 1800 m, Cajamarca, Peru.
Forms a superspecies, and sometimes considered conspecific, with *I. pulchra* and *I. personata*.
Monotypic.
Distribution. NW Peru, very locally in NE Piura, C Cajamarca and NE La Libertad.



Descriptive notes. 16·5 cm; 29–38 g. A long-ish-tailed finch with slim, pointed bill. Male has mostly grey head, browner on nape, with dark mask that fully surrounds bill, extending narrowly to forehead and to chin and upper throat; upperparts entirely greyish-brown and obscurely streaked, lower back to uppertail-coverts brownish; tail black with white outer edges; upperwing largely grey, with browner inner greater upperwing-coverts, browner-edged tertials; lower throat and breast grey, flanks also grey, belly and vent off-white; iris dark chestnut; bill and legs bright yellow, legs often more orange-yellow. Differs from *I. laeta* mainly in much less strongly patterned face and grey-brown (not rufous) back. Female is very like male, differing only in having on average less pure grey on breast and flanks and less white on centre of belly, also slightly less black on face; sometimes has dark culmen. Immature is duller than adult, lacks black on face and throat, bill dull yellow with dark culmen, legs dull yellow. Voice. Song a series of weak and quavering whistles, one ascending element sounding almost electronic, "seeew sweee? seee? seew sueeesu...".
Habitat. Desert scrub, preferring thick scrub on arid hillsides, particularly those with larger cacti. In Huancabamba found on rocky hilltop with dense scrub of acacia (*Acacia*), cacti and terrestrial bromeliads with average height 1·5 m; in Hacienda Limón in open acacia woodland with grass and thorny scrub lacking cacti and bromeliads. Tolerant of habitat degradation from grazing and logging, and known to occur also in burnt areas. At 1800–2600 m.
Food and Feeding. Feeds on seeds and other plant matter; also insects, including caterpillars. Forages at or near ground in dense vegetation, never moving far from cover. Shy, more retiring than congeners. Singly and in pairs.
Breeding. Nestlings and juveniles found in Jun–Sept; breeding season likely starts in May. No other information.
Movements. Sedentary.
Status and Conservation. VULNERABLE. Restricted-range species: present in Marañón Valley EBA and Peruvian High Andes EBA. Uncommon and local. Known from only four sites, but possibly more widespread. Global population thought unlikely to exceed 10,000 individuals. Confined to Palamba (N of Huancabamba), in extreme NE Piura, La Esperanza (NE of Santa Cruz, on Pacific slope) and Hacienda Limón (E of Celendín), both in Cajamarca, and E of R Marañón near Longotea (close to Amazonas border), in La Libertad. Habitat on Huancabamba slopes has been extensively cleared for agriculture and pasture, and no other suitable habitat known in vicinity; if this hilltop were to be burnt, the species would almost certainly disappear from this locality, the N limit of its range. Farther S it persists in heavily disturbed sites on steep slopes. Although there are no data on current size of population and trend, the species seems able to survive in disturbed habitats; no evidence of any decline exists and no serious threats have been identified at known sites. Further fieldwork desirable in order to determine if undiscovered populations exist elsewhere in the region.
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Parker *et al.* (1985), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

205. Buff-bridled Inca-finch

Incaspiza laeta

French: Chipiu à moustaches **German**: Goldschnabelammer **Spanish**: Incaspiza Bigotudo

Taxonomy. *Haemophila laeta* Salvin, 1895, Cajabamba, Cajamarca, Peru.
Monotypic.
Distribution. Upper Marañón valley in S Cajamarca, SW Amazonas, E La Libertad and adjacent NE Ancash, in NW Peru.

Descriptive notes. 14·5 cm; 19·5–23·5 g. A longish-tailed finch with slim, pointed bill. Has grey head and nape; blackish mask extending broadly to forehead and covering much of face, including area behind and below eye, and throat; large pale buff spot in lower malar area; mantle, back and scapulars rufous, becoming greyish on rump and uppertail-coverts; tail black with white outer edges; upperwing looks largely grey, with browner-edged tertials; underparts grey on breast, contrasting noticeably with buff belly and flanks, vent off-white; iris dark brown; bill bright orange-yellow; legs orange-yellow. Sexes very similar, the female somewhat duller, the crown and nape tinged with earth-brown. Immature is duller than adult, lacks black on face and throat, is streaked above and below, bill dull yellow with dark culmen, legs dull yellow. Voice. Song unrecorded. Call a high "tseet", often repeated; gives dry rasping, scold like that of a wren (Troglodytidae) when annoyed.
Habitat. Dry woodland with *Bombax* trees, cacti and thorn-scrub; 1000–2750 m.
Food and Feeding. No information on diet. Forages on ground and in bushes and trees; not so shy as other members of genus. Singly and in pairs.
Breeding. Birds in breeding condition mid-Apr to mid-Jun. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common. Has small range, within which no threats as yet identified.
Bibliography. Armani (1985), Bond (1951a), Fjeldså & Krabbe (1990), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

206. Little Inca-finch

Incaspiza watkinsi

French: Chipiu de Watkins **German**: Watkinsammer **Spanish**: Incaspiza Chico

Taxonomy. *Incaspiza watkinsi* Chapman, 1925, Perico, River Chinchipe, Cajamarca, Peru.
Monotypic.
Distribution. Lower portion of Marañón Valley in NE Cajamarca and adjacent W Amazonas, in NW Peru.

Descriptive notes. 13 cm; 17–22·5 g. A small, longish-tailed finch with slim, pointed bill. Male has head, including nape, grey, slightly paler greyish-white supercilium anterior to eye; blackish on lores and around base of bill, narrowly connected at bill base to black on chin and uppermost throat; upperparts brownish, obscurely streaked, contrasting slightly with rufous scapulars; lower back to uppertail-coverts brownish-grey; tail black with white outer edges; upperwing largely grey, with browner-edged tertials, and browner edges on inner greater coverts; throat and breast grey, grey extending to flanks, lower flanks with browner wash, belly and vent off-white; iris dark brown; bill bright yellow; legs yellow with orange tone. Female is similar to male, but crown browner, bill has dusky culmen. Immature is duller than adult, lacks black on face and throat, is more strongly streaked, including on breast, bill dull yellow with dark culmen, legs dull yellow. Voice. Song a thin and high "tsee-tsέw! swee?". Calls include high "tseet" notes.
Habitat. Undisturbed lowland desert scrub with good densities of ground bromeliads; 390–900 m.
Food and Feeding. Little information. Forages terrestrially; in pairs or singly.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common. Has very small range, within which it appears to be suffering slow to moderate decline owing to habitat degradation and expansion of oil palm (*Elaeis guineensis*) plantations. Global population not assessed; reasonably common in most areas where found. Systematics surveys required in order to monitor this species' numbers and identify key threats. Remaining native arid scrub habitats in Marañón drainage merit full protection.
Bibliography. Anon. (2010c), Armani (1985), Bond (1951a), Butchart & Stattersfield (2004), Chapman (1925), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

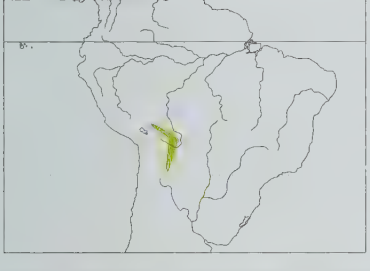
Genus *POOSPIZA* Cabanis, 1847

207. **Bay-chested Warbling-finch**

Poospiza thoracica

French: Chipiu à poitrine baie **Spanish**: Monterita Pectoral
German: Maronenbrust-Ammerfink

Taxonomy. *Fringilla thoracica* Nordmann, 1835, Brazil.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Monotypic.
Distribution. Coastal mountains along Minas Gerais–Rio de Janeiro border, and highlands from E São Paulo and Paraná S to NE Rio Grande do Sul, in SE Brazil.



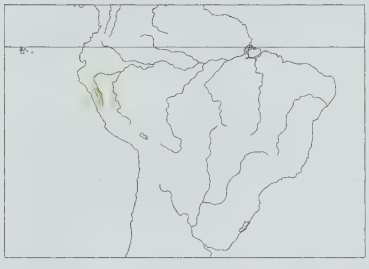
Descriptive notes. 13·5 cm; 11–12·8 g. A dainty warbling-finch with rather petite bill with gently curved culmen. Male has grey head, large and bold white crescent below eye, blackish area around eye creating masked appearance, well-demarcated white throat and malar region; grey of head blends into slightly browner back, rump brownish-grey; tail greyish-brown; upperwing greyish, bases and edges of outer primaries white (creating white flash on folded wing), marginal coverts white (showing as white at bend of wing); below, bright bay-coloured breastband, this colour extending down flanks, with lower breast and belly white, crissum creamy buff; iris dark brown; bill dark grey, darker culmen and tip; legs reddish-grey to greyish-brown. Female is like male, but slightly paler, colours less saturated. Juvenile undescribed. Voice. Song a pleasant and sweet series of three or so repeated elements, elements separated by a short silence (but not enough to break up rhythm of song), "tsup tseep tsweet tsup tseep tsup sweet...". Call a flat "chuup" and also a higher pitched "tiip".
Habitat. Montane-forest edge and shrubby situations or open woodland, as well as clearings with scattered shrubs or trees; regularly in second-growth thickets. At 800–1500 m.
Food and Feeding. Small invertebrates; also fruit, such as the melastome *Leandra sublanata*. Gleans invertebrates from foliage. Forages in pairs and in small flocks; often a component of mixed foraging flocks.
Breeding. Breeding reported in Jan. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in various parks and preserves in Atlantic Forest zone of Brazil, including Itatiaia National Park, where it is common.
Bibliography. Armani (1985), Belton (1985), Gridi-Papp *et al.* (2004), Parrini *et al.* (2009), Ridgely & Tudor (1989), Sick (1993), de Vasconcelos & D'Angelo Neto (2009).

208. **Bolivian Warbling-finch**

Poospiza boliviana

French: Chipiu de Bolivie **German**: Zimtbrust-Ammerfink **Spanish**: Monterita Boliviana

Taxonomy. *Poospiza boliviana* Sharpe, 1888, Bolivia.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. This species is thought to be either sister to *P. ornata* or part of a clade that also includes latter. Monotypic.
Distribution. Andes of W Bolivia (La Paz, Cochabamba, W Santa Cruz, W Chuquisaca and W Tarija) and extreme NW Argentina (N Salta).



Descriptive notes. 15–16 cm. A standard-shaped warbling-finch with relatively small and pointed bill. Plumage is greyish-brown above, with slightly more greyish crown, dark grey face bordered above by long white supercilium; tail dusky, broad white tips on outer pair of rectrices; upperwing greyish-brown like upperparts, secondaries edged rufous; white throat, chestnut breastband that extends down to flanks, with belly and vent white, crissum buffy white; iris dark brown; bill dark grey, black tip and culmen; legs blackish. Differs from *P. hypocondria* in having much more rufous below, no malar stripe. Sexes alike. Juvenile is paler and duller than adult, with supercilium tinged buff, underparts faintly streaked. Voice. Song not described. Call a sharp "twiip".
Habitat. Dry and semi-humid scrub, including open woodland, sometimes with *Polylepis* bushes, scrub, shrubby hillsides and riparian thickets, also dry scrub mixed with cacti; also hedgerows adjacent to agricultural fields. At 1600–3100 m.
Food and Feeding. Behaviour suggests diet of arthropods and seeds. Forages on ground and in dense shrubbery. Singly and in pairs; also with other finches such as *P. hypocondria* or *P. torquata*, as well as *Zonotrichia capensis*.
Breeding. Singing reported in Mar and juveniles seen in Apr. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Rare to uncommon. Previously thought to be confined to Bolivia, but recently recorded in extreme NW Argentina. Occurs in three protected areas in Bolivia: Tunari National Park (Cochabamba), Amboró National Park (Santa Cruz) and Tariquía National Reserve (Tarija).
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Klicka *et al.* (2007), Lougheed *et al.* (2000), Mazar Barnett *et al.* (2001), Ridgely & Tudor (1989).

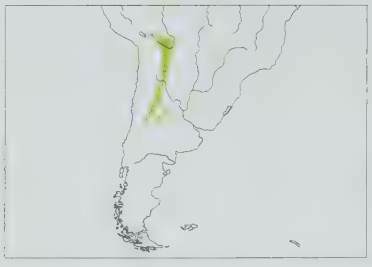
209. **Plain-tailed Warbling-finch**

Poospiza alticola

French: Chipiu alticole **German**: Grauschwanz-Ammerfink **Spanish**: Monterita de Cajamarca

Taxonomy. *Poospiza alticola* Salvin, 1895, Huamachuco, 10,400 feet [c. 3170 m], La Libertad, Peru.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Earlier research suggests that this species is most closely related to *P. torquata*, *P. melanoleuca* and *P. erythrophrys*. Monotypic.
Distribution. Upper Marañón Valley in S Cajamarca, La Libertad and E Ancash (essentially W of R Marañón, except for sites in W La Libertad), in W Peru.

Descriptive notes. 16 cm. A slim and long-tailed warbling-finch with relatively long and finely pointed bill. Male is greyish-olive above, darker on crown; face blackish-brown, bordered above by long white supercilium, and below by white submoustachial stripe; tail dusky brown and unmarked; upperwing dusky, primaries with thin pale edges; throat white, bordered by narrow dark malar stripe, centre of breast and belly also white, side of breast rufous, this colour continuing down flank, washed grey on rear flank, crissum greyish-buff; iris dark brown; bill black, lower mandible partially brownish-orange; legs dusky. Female is slightly paler and duller than male. Juvenile is dusky above and on throat and breast, darkest on head and nearly lacking paler supercilium, with flanks and vent buff. Voice. Song a warble, rich in quality, "chew tew-tueeee?". Calls buzzy in nature, sometimes given in rapid series, "zree-zree-zree"; also a sharp "tip".
Habitat. Montane scrub, shrubby areas and low woodland, particularly ravines. Found mostly in *Polylepis–Gynoxys* woodland or woodland dominated by alder (*Alnus*), and other forests where *Gynoxys* present; is either strongly associated with *Gynoxys* or perhaps a *Gynoxys* specialist. At 2900–4300 m, mostly above 3500 m.
Food and Feeding. Feeds on arthropods; also on sugary secretions from underside of *Gynoxys* leaves. Forages both in foliage of dense shrubs and on ground. Typically in pairs; often in mixed-species foraging flocks. May be in close competition with Tit-like Dacnis (*Xenodacnis parina*), another *Gynoxys* specialist.
Breeding. Birds in breeding condition in Sept and juveniles found in Feb–Mar; season possibly Oct–Feb. No other information.
Movements. Sedentary.
Status and Conservation. ENDANGERED. Rare to locally uncommon within its restricted range. Has fairly small range, within which remaining area of suitable habitat decreasing, and populations severely fragmented. Global population probably very small; estimated to lie in the range 1000–2499 individuals. Occurs at generally low densities. Most reports are from Cordillera Blanca (in Ancash), where fairly common at Morococha and in Huascarán National Park; up to 2·5 birds/km² at latter locality. Main continuing threats to this species are cutting of woodland for firewood, and lack of regeneration because of burning and intensive grazing, thus reducing the extent of its preferred habitat of mixed *Polylepis–Gynoxys* woodlands. Additional adverse factors include the shift from camelid-farming to the farming of sheep and cattle, and soil erosion and degradation through agricultural intensification, also road-building; further, afforestation projects have often been inappropriate, with the use of exotic tree species instead of native ones. The species is present in Huascarán National Park, but even within this protected area habitat degradation continues.
Bibliography. Anon. (2010c), Armani (1985), Bond (1951a), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Klicka *et al.* (2007), Lougheed *et al.* (2000), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).



210. **Rufous-sided Warbling-finch**

Poospiza hypocondria

French: Chipiu à flancs roux **German**: Rotflanken-Ammerfink **Spanish**: Monterita Pechigrís

Taxonomy. *Emberiza hypocondria* d'Orbigny and Lafresnaye, 1837, Sicasica, Bolivia.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. A different study suggests that this species is most closely related to *P. caesar*. Species name often misspelt "*hypochondria*". Two subspecies recognized.
Subspecies and Distribution.
P. h. hypocondria (d'Orbigny & Lafresnaye, 1837) – Andes of Bolivia from S La Paz S (including C Cochabamba, W Santa Cruz, W Chuquisaca and N & E Potosí) to W Tarija.
P. h. affinis Berlepsch, 1906 – NW Argentina from Salta and Jujuy S along E slope of Andes to S San Juan and N Mendoza; also W Córdoba in winter.
Descriptive notes. 13·5–16·5 cm; 18–24·5 g. A relatively long-tailed warbling-finch. Male nominate race is brownish-grey above, face greyer, long buff-white supercilium, narrow buff subocular

On following pages: 211. Rusty-browed Warbling-finch (*Poospiza erythrophrys*); 212. Cinnamon Warbling-finch (*Poospiza ornata*); 213. Black-and-rufous Warbling-finch (*Poospiza nigrorufa*); 214. Buff-throated Warbling-finch (*Poospiza lateralis*); 215. Grey-throated Warbling-finch (*Poospiza cabanisi*); 216. Rufous-breasted Warbling-finch (*Poospiza rubecula*); 217. Chestnut-breasted Mountain-finch (*Poospiza caesar*); 218. Collared Warbling-finch (*Poospiza hispaniolensis*); 219. Ringed Warbling-finch (*Poospiza torquata*); 220. Black-capped Warbling-finch (*Poospiza melanoleuca*); 221. Cinereous Warbling-finch (*Poospiza cinerea*); 222. Cochabamba Mountain-finch (*Compsospiza garleppi*); 223. Tucuman Mountain-finch (*Compsospiza baeri*).

crescent, broad buffish-white submoustachail stripe, narrow dark malar stripe; tail dark dusky brown, outer feather with entirely white outer web and white distal half of inner web, next two rectrices with decreasing amount of white on tip of inner web; upperwing largely brownish-grey, with buffy fringes and tips forming narrow wingbars; throat white, breast and upper flanks grey, lower flanks orange-rufous, lower breast, belly and vent buff; iris dark brown; bill grey, with blackish on upper mandible; legs blackish. Female is very like male, but marginally paler, separable only when sexes observed together. Juvenile is buffy brown above, supercilium before eye ochraceous buff, breast and belly ochraceous buff, becoming pale cinnamon ochraceous on flanks, with side of breast and flanks obscurely streaked; immature similar, but upperparts darker and browner, throat, breast and belly dark buff, greyish wash on side of breast. Race *affinis* is larger than nominate, more greyish on rump and buffier below, with more restricted white on outer tail feathers. VOICE. Song jumbled, sounding at times out of tune, and with very short stops between elements, "tch-zwe-ta-chp-zwe-ta-cshw-zwe-ta...", less melodious and more hurried than that of many congeners. Call a high "zwee".

Habitat. Thick shrubby areas, particularly on hillsides and ravines, in semi-arid regions, also shrubs and hedges adjacent to agriculture; in Bolivia can be found also at edge of *Polylepis* forest. At 2500 m to 4200 m; in non-breeding season down to 1000 m in extreme S part of range.

Food and Feeding. Feeds largely on insects; stomach contents include insects and plant matter. Forages in dense shrubbery, rarely on ground. Often probes in dead-leaf clusters. May wag tail from side to side, although never really cocking it. Found in pairs and small groups; often in mixed-species flocks.

Breeding. Juveniles found between Mar and Jun. No other information.

Movements. Mostly sedentary. In S part of range some make post-breeding descent to foothills of Sierras de Córdoba (Argentina); in Bolivia, seasonal variation in numbers detected at Liriuni–San Miguel (in Cochabamba), with higher numbers in austral winter, suggesting local seasonal movements.

Status and Conservation. Not globally threatened. Uncommon to fairly common throughout its range. No immediate threats identified.

Bibliography. Armani (1985), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Lougheed *et al.* (2000), Mazar Barnett, Clark *et al.* (1998), Ridgely & Tudor (1989).

211. Rusty-browed Warbling-finch

Poospiza erythrophrys

French: Chipiu à sourcils roux **German**: Rostbrauen-Ammerfink **Spanish**: Monterita Cejirrufa

Taxonomy. *Poospiza erythrophrys* P. L. Sclater, 1881, Sierra de Totoral, Catamarca, Argentina.

New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Molecular evidence suggests that this species is part of a clade that also includes *P. alticola*, *P. torquata* and *P. melanoleuca*, where similar-looking *P. ornata* was found not to be a close relative. Two subspecies recognized.

Subspecies and Distribution.

P. e. cochabambae Gyldenstolpe, 1941– C & S Bolivia (Cochabamba and W Santa Cruz S to Chuquisaca).

P. e. erythrophrys P. L. Sclater, 1881 – S Bolivia (Tarija) and NW Argentina (Jujuy and Salta S to Tucumán and Catamarca).

Descriptive notes. 13·5–14 cm; 13·2–15 g. A slim warbling-finch with small and thin bill. Male nominate race has crown and face blue-grey, long deep rufous supercilium; upperparts greyish-brown; tail brown, white outer rectrices; upperwing brownish, outer primaries with white edging (creating white flash on folded wing), greater primary coverts with white outer edges; throat and breast dark rufous, flanks and belly paler, vent cinnamon; iris dark brown; bill blue-grey, black culmen; legs dusky. Differs from *Compsospiza garleppi* and *Compsospiza baeri* in smaller size, white in tail and wing, browner (less grey) back, and generally less solidly grey-and-rufous coloration. Female is slightly paler below and more brownish-grey, less blue-grey, above than male. Juvenile is paler and duller than adult, pale cinnamon below, and white of wing replaced by buff. Race *cochabambae* is more greyish on back, thus little colour contrast between back and crown, also has more striking white wingpanel on closed primaries, and entire outer half of greater secondary coverts white. VOICE. Song a melodious set of three or four elements given in a sequence and then repeated in same order, "chwit cheet swee, chwit cheet swee..." or "swee ti-tip swee cha, swee ti-tip swee cha..."; some song versions sibilant and high-pitched, others lower and more robust-sounding. Call a sharp "chwip", sometimes repeated in excitement.

Habitat. Edge of montane (Yungas) forest, often at edge of alder (*Alnus*) groves, also second growth and shrubby ravines. At one site sampled in Tucumán, in Argentina, mature Yungas forest was preferred habitat, with minor use of secondary growth. At 900–3100 m.

Food and Feeding. Invertebrates and fruits recorded in diet. Analyses of faecal samples gave a mixture of invertebrates, including spiders (Araneae), beetles (Coleoptera), flies (Diptera), and ants and wasps (Hymenoptera), as well as fruit. Forages in low trees and shrubs, rarely on ground. Gleans insects from leaves. In pairs and small groups; often joins mixed-species foraging flocks.

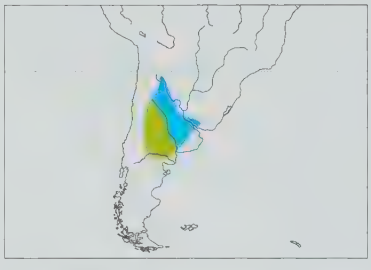
Breeding. Season Nov–Jan in S of range (Tucumán). Nest a half-sphere made from lichens and fibres of ferns. Clutch 3 eggs, blue-white with brown and blackish blotches, these particularly around wide end. No other information.

Movements. Largely sedentary. One mist-netting study noted presence in both dry and wet seasons in the Myrtaceae zone of Yungas forest (1200–1600 m), but presence only during dry (winter) season in lower transitional zone (900–1200 m), suggesting some seasonal altitudinal movements.

Status and Conservation. Not globally threatened. Locally common. Has reasonably extensive range, within which not known to be at any risk.

Bibliography. Armani (1985), Blake & Rougès (1997), Fjeldså & Krabbe (1990), Lougheed *et al.* (2000), de la Peña (1989), Ridgely & Tudor (1989), Rougès & Blake (2001).

212. Cinnamon Warbling-finch



Poospiza ornata

French: Chipiu cannelle **German**: Schmuckammerfink **Spanish**: Monterita Canela

Taxonomy. *Phrygilus ornatus* Leybold, 1865, between Paso Portillo and Melocotón, Mendoza, Argentina.

New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Molecular evidence suggests that this species is either sister to *P. boliviana* or part of a clade that also includes latter. Monotypic.

Distribution. Breeds in C Argentina from San Juan and La Rioja S through Mendoza, San Luis, N La Pampa and W Buenos Aires; non-breeding also N & E to Salta, Tucumán, Córdoba and N Buenos Aires.

Descriptive notes. 13 cm; 11·8–12·7 g. A relatively stocky and thick-billed warbling-finch. Male has head, including crown and nape, slate-grey, bold pale cinnamon supercilium widening behind eye, narrow cinnamon lower eye-crescent; upperparts chestnut (some have grey on outer scapulars), paler chestnut on lower back and rump, with uppertail-coverts grey; tail brownish-grey, white outer rectrices; upperwing brownish-grey, lesser upperwing-coverts grey, median and greater coverts broadly tipped white (creating two bold white wingbars, lower one very wide and nearly forming white panel on folded wing), primaries with narrow white fringes, wider and more obvious white fringes on secondaries (creating indistinct white inner flash on folded wing); chin and upper throat cinnamon, turning rufous on breast, and paler cinnamon farther back on belly, becoming whitish with cinnamon wash on vent and crissum; iris dark brown; upper mandible black with blue-grey cutting edge, lower mandible blue-grey; legs blackish. Female is similar to male, but paler cinnamon below, wingbars may be buffy. Juvenile undescribed; first-year male slightly duller than adult, with narrower wingbars and less white on primaries and secondaries. VOICE. Song a repeated series of 3–4 notes, timbre of voice with an almost buzzy nature, "tzeew chweew tzew cheew, tzeew chweew tzew cheew...", more sibilant and hurried than that of congeners.

Habitat. Arid Monte Desert woodland, and woodland edge; also taller scrub in xeric Andean foothill ravines. In open woodlands forages in taller and denser situations than those exploited by *P. torquata*. Sea-level to 1000 m.

Food and Feeding. Primarily seeds of perennial grasses, in particular *Sporobolus cryptandrus* and *Pappophorum*, also seeds of *Capparis atamisquea* tree; this contrasts with diet of sympatric *P. torquata* (which relies on arthropods during breeding season). Forages close to or on ground; also in trees and shrubbery, then preferring *Prosopis flexuosa* and *Capparis atamisquea*. Often forages in pairs.

Breeding. Nesting in Monte Desert (Mendoza) variable from year to year, e.g. in Ñacuñán did not breed in drier years of 1995–1996 and 1998–1999, but in wetter 1997–1998 began egg-laying early Dec and continued to mid-Jan. Nest a large cup (larger yet shallower than that of sympatric *P. torquata*) made from grass stems and hairy achenes of composites, lined with fine vegetable fibres; of 60 nests in Mendoza, 45 placed in chañar (*Geoffroea decorticans*) and 15 in zampa (*Atriplex lampa*), chañar trees chosen were shorter than average available in environment; overall, nest placed 0·8 m above ground in plants with average height 1·6 m (average 1·8 m up in chañar, 1·3 m from ground in zampa); common creosote bush (*Larrea divaricata*) avoided. Clutch 3 eggs, whitish with evenly distributed brown spots; no information on incubation and nestling periods.

Movements. Partial migrant, some moving N & E after breeding; also, breeding varies from year to year depending on local rainfall patterns (accordingly, breeding distribution somewhat fluid). In E Mendoza, arrives in spring and numbers build up in summer; breeds if seed supply adequate, but in dry years may arrive in spring and desert the area for other possible breeding sites, perhaps farther S (but destination unclear). This facultative migratory behaviour creates great fluctuations in densities from year to year, and breeding range may shift annually within Monte Desert and *espinal* zones; even so, in E Mendoza all leave during autumn and winter, presumably moving N for winter. In NE Argentina, two records from Entre Ríos and reported also from Santa Fe, and at least one winter record from Uruguay (Canelones Department), all suggesting that E movement in winter months perhaps more widespread than previously realized.

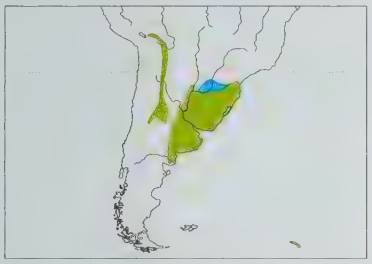
Status and Conservation. Not globally threatened. Uncommon and local; status at localities changes annually, depending on rainfall patterns and availability of seed stock in environment. At Ñacuñán (Mendoza), densities varied from 0·6 birds/ha in shrubland to 0·9 birds/ha in open woodlands.

Bibliography. Armani (1985), Azpiroz (2003a), Azpiroz & Menéndez (2008), Blendinger (2005a), Blendinger & Ojeda (2001), Cueto, de Casenave & Marone (2008), Cueto, Marone & de Casenave (2006), Klicka *et al.* (2007), Lougheed *et al.* (2000), Marone (1992a, 1992b), Mezquida (2004), Mezquida & Marone (2003), Milesi *et al.* (2008), de la Peña (1989), Ridgely & Tudor (1989), Roesler *et al.* (2006), Zackrisson (1972).

213. Black-and-rufous Warbling-finch

Poospiza nigrorufa

French: Chipiu noiroux **German**: Rotbrust-Ammerfink **Spanish**: Monterita Sietevestidos
Other common names: Black-and-chestnut/Chestnut Warbling-finch (*whitii* and *wagneri*)



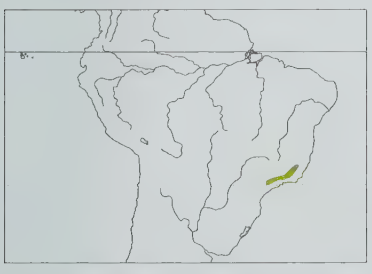
Taxonomy. *Emberiza nigro-rufa* d'Orbigny and Lafresnaye, 1837, Santa Fe, Argentina.

New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Closest relatives of present species uncertain; further study required. Races *whitii* and *wagneri* sometimes treated together as a separate species, differing from nominate in song, habitat, and both juvenile and adult plumages; this treatment seems reasonable, but further details of these differences, in particular vocal differences, are needed. Race *wagneri* poorly differentiated from *whitii*, and perhaps better synonymized. Three subspecies currently recognized.

Subspecies and Distribution.

P. n. wagneri Stolzmann, 1926 – La Paz (around Mt Chulumaní), in W Bolivia.

P. n. whitii P. L. Sclater, 1883 – Bolivia (Cochabamba, Santa Cruz, Chuquisaca and Tarija) and NW & NC Argentina (Salta, Jujuy and Tucumán S to E San Juan and N Mendoza, also W Córdoba and highlands of San Luis).
P. n. nigrorufa (d'Orbigny & Lafresnaye, 1837) – SE Brazil (Santa Catarina and Rio Grande do Sul), Uruguay and NE Argentina (E Formosa, Corrientes and Misiones S to E Córdoba, E La Pampa, E Rio Negro and Buenos Aires); non-breeding also SE Paraguay (Ñeembucú, C Paraguay and Alto Paraná regions).

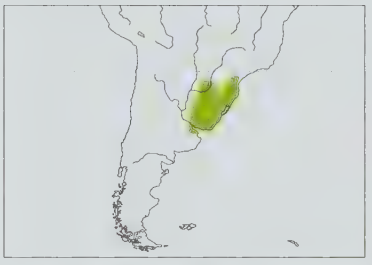


Descriptive notes. 15 cm; 13–20·7 g. A medium-sized warbling-finch with rather long and pointed bill, also long and somewhat round-tipped tail. Nominate race has crown and face blackish-grey, long and narrow white supercilium becoming cinnamon a short distance behind eye, narrow white submoustachial stripe; nape and upperparts paler brownish-grey; tail dusky, outer rectrices with large, square-cut white tips; upperwing plain blackish-grey; chin white, throat and breast rufous, this colour extending to flanks, becoming paler cinnamon on vent and crissum; middle of belly white, extending towards breast in inverted V-shape; iris brown; bill dark grey, black culmen and tip; legs blackish. Sexes similar. Juvenile lacks cinnamon supercilium, is off-white and densely streaked brown below. Race *whitii* is slate-grey (rather than brownish-grey) above, deeper chestnut below, with more restricted white on belly, much more extensive white on outer rectrices, juvenile pale ochre to cinnamon below with flanks streaked and darker olive with narrow pale streaking on breast and breast side, immature similar to adult, but paler, lacking streaking below; *wagneri* is dubiously distinct from previous, but said to have more extensive white moustache. Voice. Song of nominate race a pleasant and melodious repeated series of 3 notes, with resonant quality, first 2 notes identical, "tweet tweet-chew, tweet tweet-chew...", sometimes transliterated as "Who dressed you?". Song of *whitii* differs in various respects from that of nominate, is delivered more slowly, tends to be lower-pitched, and much more variable and complex, more like a continuous song, with multiple elements cycled through in delivery reminiscent of fast Red-eyed Vireo (*Vireo olivaceus*) song, and also includes doubled elements ("tip-tip") and low-pitched quavering sounds ("pweerr"), e.g. "tchew tip-tip chew-chew twiip chew tip-tip tweee seewup pweerrr chew-chew...". Call a high "tziip".
Habitat. Nominate race found in shrubby areas and woodlands, including hackberry (*Celtis tala*) woodlands (known in Argentina as "*talares*") within grassy *pampas*, also shrubby areas adjacent to marshes, bushy areas near water, thickets of pampas grass (*Cortaderia*) adjacent to woodland or shrublands, also suburban areas and gardens; sea-level to 500 m. Race *whitii* occurs in shrubby thickets, humid secondary growth, clumps of trees along roadsides, and highland agricultural areas with adjacent shrubbery, at 600–2500 m.
Food and Feeding. Little information on diet. Forages on ground, or near ground. Often found in pairs; race *whitii* often forms part of mixed-species foraging flocks.
Breeding. Nests recorded Oct–Jan in NE Argentina; eggs recorded in Jan in La Paz (Bolivia, race *wagneri*), and in Argentina egg dates for race *whitii* in Nov (Córdoba) and Apr (Tucumán), suggesting later timing of breeding by latter race. Nest a cup made from dry grasses, placed usually less than 1 m above ground and sometimes woven in with leaves in shrubbery. Clutch 3–4 eggs, pale blue with dark spots throughout; incubation c. 14 days; chicks fed by both parents, nestling period 16 days.
Movements. Largely sedentary. Race *whitii* apparently makes seasonal movements in drier parts of its range, e.g. at Tambo (Santa Cruz), in Bolivia, fairly common in wet season, but only a rare visitor in dry season. Similarly, nominate race recorded in Paraguay only during austral winter, suggesting that it is a partial migrant.
Status and Conservation. Not globally threatened. Nominate race common; *whitii* fairly common in most of range, patchy and uncommon in N part; *wagneri* uncommon.
Bibliography. Armani (1985), Belton (1985), Fjeldså & Krabbe (1990), Hayes (1995), Lougheed *et al.* (2000), de la Peña (1989), Ridgely & Tudor (1989), Sick (1993), Wetmore (1926).

214. Buff-throated Warbling-finch
Poospiza lateralis

French: Chipiu à croupion roux **German**: Rotbürzel-Ammerfink **Spanish**: Monterita Culirrufa
Other common names: Red-rumped Warbling-finch (when treated as conspecific with *P. cabanisi*)

Taxonomy. *Fringilla lateralis* Nordmann, 1835, Rio de Janeiro, Brazil.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Closest relatives of present species uncertain; further study required. Until recently thought to be conspecific with *P. cabanisi*, but separated on basis of differences in song and plumage. Monotypic.
Distribution. Mountains of Espírito Santo, Rio de Janeiro, N São Paulo and adjacent parts of Minas Gerais, in SE Brazil.

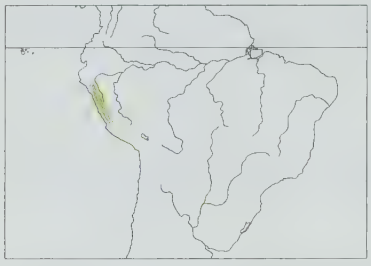


Descriptive notes. 15 cm; 16·1–21 g. A medium-sized warbling-finch with somewhat small bill. Male has head grey, darker on crown, with indistinct or almost non-existent pale greyish supercilium (most visible in front of eye, where becomes buffy-white); grey continues on nape and side of neck and throughout mantle, back and scapulars, with lower back to uppertail-coverts rufous; tail blackish with brown edgings, outer two pairs of rectrices nearly entirely white, and next pair has only terminal third white; upperwing greyish, including shoulder (lesser upperwing-coverts), median and greater coverts grey, outer greater coverts tipped whitish, tertials grey, outer primaries strongly edged white (creating white flash on folded wing); chin whitish, throat buff, becoming darker buff on centre of breast, breast side grey like back, flanks contrastingly and broadly rufous (almost reaching centre of lower breast), vent and crissum also rufous, central belly white; iris dark chestnut; bill greyish, usually blacker above and paler, often bluer, below; legs dark grey. Female is slightly paler, less colour-saturated than male. Immature is washed greenish above, with yellowish supercilium, forehead and throat. Voice. Song a series of 4 repeated notes, "tsip tsip tsip-tsip tsip tsap tsip...", seldom varying from this pattern (unlike much more complex song of *P. cabanisi*); monotonous repetitive nature of song has led some to compare it with songs of White-vented Violet-ear (*Colibri serrirostris*). Call a clean sharp "chap!".
Habitat. Moist montane Atlantic Forest, particularly in areas of *Podocarpus* and *Araucaria*; 350–1800 m.
Food and Feeding. Food appears to be a mix of invertebrates and seeds. In one detailed observation at massive hatch of winged termites (Isoptera) in NE São Paulo, this was the most common avian species; total of 50–70 individuals congregated and fed on the termites, by sallying up and capturing them on the wing. Forages generally alone and in pairs; also in small groups during non-breeding season.
Breeding. No information.
Movements. Sedentary; no evidence of altitudinal movements.
Status and Conservation. Not globally threatened. Fairly common to common; can be the passerine with the highest density in some areas of *Podocarpus–Araucaria*. Well represented in several protected areas in Brazil, including Itatiaia National Park and Campos do Jordão State Park, among others.
Bibliography. Armani (1985), Assis *et al.* (2007), Barbosa & de Almeida (2008), Lougheed *et al.* (2000), Olson & Alvarenga (2006), de la Peña (1989), Ridgely & Tudor (1989), Sick (1993).

215. Grey-throated Warbling-finch
Poospiza cabanisi

French: Chipiu de Cabanis **German**: Graubrust-Ammerfink **Spanish**: Monterita de Cabanis
Other common names: Red-rumped Warbling-finch (when treated as conspecific with *P. lateralis*)

Taxonomy. *Poospiza cabanisi* Bonaparte, 1850, Paraguay = probably Bonpland, Misiones, Argentina.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Closest relatives of present species uncertain; further study required. Until recently thought to be conspecific with *P. lateralis*, but separated on basis of differences in song and plumage. Monotypic.
Distribution. S Paraguay (Alto Paraná and Central), NE Argentina (Misiones and Corrientes S through Entre Rios to extreme NE Buenos Aires), SE Brazil (S São Paulo and Paraná S to Rio Grande do Sul) and Uruguay.



Descriptive notes. 15 cm; 18–21 g. A medium-sized warbling-finch with somewhat stout, yet point-tipped bill. Male has head grey, darker on crown, with slightly paler grey to white narrow supercilium, pale grey speckling on cheek, pale greyish to white moustachial stripe; grey continues on nape and side of neck, becoming brownish on mantle, scapulars and back, with lower back to uppertail-coverts rufous; tail blackish with brown edgings, almost half of outermost rectrix white, less than a third of adjacent feather white; upperwing dusky, greyish shoulder (lesser upperwing-coverts), inner greater coverts edged brown, outer greater coverts with paler edges and whiter tips, tertials edged brown, primaries strongly edged white (creating white flash on folded wing); throat pale grey to white, grey continuing to breast, flanks contrastingly rufous, vent and crissum pale cinnamon, central belly white; iris chestnut; bill dull yellowish-grey, blackish culmen; legs dusky grey to brownish-flesh. Female is duller and slightly less colour-saturated than male. Immature has yellowish supercilium, and yellowish wash on throat. Voice. Song a series of 4–5 repeated notes, high-pitched and with sibilant timbre, "tcheew twip-chip chew, tcheew twip-chip chew...", more variable and less monotonous than that of *P. lateralis*. Call quite distinctive, nasal and sharp, with marked harmonic structure, "zzchap", sometimes doubled or given in series, much less sharp and more nasal than call of *P. lateralis*.
Habitat. Riparian forest, gallery forest, humid forest edge, and open woodlands; from sea-level up to 500 m.
Food and Feeding. Invertebrates and seeds. Forages usually within 2 m of ground, rarely on ground. Forages alone and in pairs; also in small groups during non-breeding season.
Breeding. Season Oct–Dec. Nest a cup made from vegetable fibres. Clutch 3 eggs, blue-green with black blotches. Often parasitized by Shiny Cowbird (*Molothrus bonariensis*). No further information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common throughout its reasonably extensive range.
Bibliography. Armani (1985), Assis *et al.* (2007), Belton (1985), Friedmann (1938), Hayes (1995), Lougheed *et al.* (2000), de la Peña (1989), Ridgely & Tudor (1989).

216. Rufous-breasted Warbling-finch
Poospiza rubecula

French: Chipiu rougegorge **German**: Rostbauch-Ammerfink **Spanish**: Monterita Pechirrufa

Taxonomy. *Poospiza rubecula* Salvin, 1895, Huamachuco, 10,400 feet [c. 3170 m], La Libertad, Peru.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within present genus, is sister to that clade. Closest relatives of present species uncertain; further study required. Has been hypothesized that, on basis of plumage similarities, it is closely related to *Compsospiza* mountain-finches. Monotypic.
Distribution. W slope of Peruvian Andes from S Cajamarca and La Libertad S to Lima and probably Ica.
Descriptive notes. 14–16·5 cm. A rather small-billed warbling-finch, small and triangular bill reminiscent of that of a conebill (*Conirostrum*). Has blackish face contrasting with striking orange-rufous upper forehead and supercilium, and crown and rest of head lead-grey; upperparts grey, sometimes a little more olive-grey on back; tail and upperwing plain dusky; chin blackish like face, throat, breast and belly orange-rufous, flanks greyish (slightly paler than upperparts), centre of

belly white, crissum rufous; iris dark brown; bill black, blue-grey base of lower mandible; legs purplish-pink. Sexes similar. Immature is grey above, lacks supercilium, mixed white and rufous below, with grey streaks on breast and flanks. Voice. Song a slightly accelerating and variable rich warble with emphatic nature, and squeaky timbre, sometimes ends on buzzy note, "sweeu tichit twee para-chwéé?".

Habitat. Bushy undergrowth of mixed dry Andean woodlands of short stature dominated by *Oreopanax*, *Myrcianthes* and *Escallonia*, montane scrub and also dry scrub at edge of *Polylepis* forests; also thick composite scrub on slopes, and most closely associated with the composite shrubs *Eupatorium* and *Gynoxys*. At 2500–3800 m.

Food and Feeding. Young leaf buds, berries and seeds recorded as eaten. Forages in low shrubs or trees. Singly and in pairs; sometimes forms part of mixed-species foraging flocks.

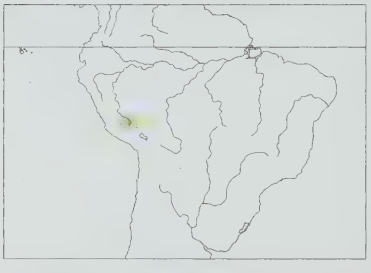
Breeding. Little known. Adults feeding juveniles in Jul, and immatures seen between Jan and May; individuals singing in Lima Mar–Apr. No other information.

Movements. Mostly sedentary; some evidence of minor elevational movements.

Status and Conservation. ENDANGERED. Very rare. Little known. Has been found at just a handful of isolated localities. Densities very low at sites where it does occur, and estimated that total population is very small, in range 250–999 individuals. In Zárate Forest (Lima), only six individuals have been recorded, but this more than at any other locality. This species has already suffered extensive habitat loss and degradation, and this is continuing owing particularly to cutting of woodland for timber and firewood, overgrazing by livestock, and planting of non-native trees. Agricultural intensification and a shift from camelid-rearing to the farming of more destructive livestock (goats, sheep and cattle) have been main causes of habitat loss; more recently, afforestation with exotic trees, e.g. eucalypts (*Eucalyptus*) and pines (*Pinus*), represent a new and highly adverse factor. Rates of habitat loss and degradation have increased in recent years within range occupied by this emberizid. Recorded within Huascarán National Park, in Cordillera Blanca (Ancash), but even here habitat degradation is occurring. Surveys required in order to determine the species' precise distribution, and effective protection of Zárate Forest a priority.

Bibliography. Anon. (2010c), Armani (1985), Barrio (1995), Bond (1951a), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Lougheed *et al.* (2000), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stattersfield & Capper (2000).

217. Chestnut-breasted Mountain-finch



Poospiza caesar

French: Chipiu césar **German**: Kaiserammerfink **Spanish**: Monterita Pechicastaña
Other common names: Chestnut-bellied/Cuzco Mountain-finch, Chestnut Warbling-finch

Taxonomy. *Poospiza caesar* P. L. Sclater and Salvin, 1869, Tinta, Cuzco, Peru.

Formerly classified in its own genus, *Poospizopsis*. New molecular data indicate that present genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within this genus, is sister to that clade. A molecular-genetic study of various members of the genus suggests that present species is sister to *P. hypocondria*. Monotypic.

Distribution. Andes of Apurímac and Cuzco, in SE Peru.

Descriptive notes. 17–18·5 cm. A large and relatively stocky, robust finch with long, stout bill. Has black forehead and mask, strongly contrasting narrow white supercilium starting just in front and above eye, otherwise crown and rest of head grey, continuing as grey upperparts to rump and uppertail-coverts; tail grey, upperwing plain dark grey; chin and throat white, contrasting wide rufous breastband; flanks grey, belly white, crissum rufous like breast; iris dark brown; bill black, small grey patch at base of lower mandible; legs blackish. Sexes alike. Juvenile is similar to adult, but grey and blackish areas tinged brown, has buff wash on throat. Voice. Song a rich and variable warble with squeaky timbre, not unlike song of Golden-billed Saltator (*Saltator aurantiirostris*) but more complex and incorporating buzzy notes, "chip cheeo swipchea", lasts 2–3 seconds and repeated at intervals of c. 10 seconds. Call a thin "tsee?".

Habitat. Highland scrub and low woodlands in semi-arid zone, including secondary growth and edge situations; preference for low shrubbery mixed with taller columnar cacti, and sometimes in mosaic with open areas and patches of taller woodland. At 2900–3500 m.

Food and Feeding. No details of diet. Forages mostly on ground, otherwise skulking through dense vegetation close to ground; more terrestrial than congeners. Usually in pairs; may join mixed-species foraging flocks at times.

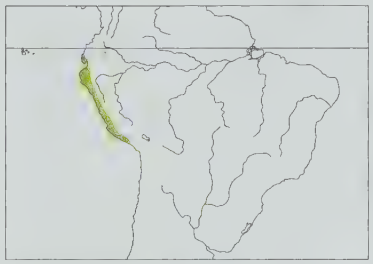
Breeding. Males defending territories in Mar in Cuzco and male in breeding condition in Apr. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Locally fairly common. No significant threats identified.

Bibliography. Bond (1951a), Estrada & Rondan (2009), Fjeldså & Krabbe (1990), Lougheed *et al.* (2000), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

218. Collared Warbling-finch



Poospiza hispaniolensis

French: Chipiu à col noir **German**: Schwarzbrust-Ammerfink **Spanish**: Monterita Collareja

Taxonomy. *Poospiza hispaniolensis* Bonaparte, 1850, Santo Domingo; error = Peru.

New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within this genus, is sister to that clade. A recent molecular-genetic study suggested that this species is rather distantly related to very similar-looking *P. torquata*; found to have a basal position in genus in some analyses, and in a clade with *P. ornata* and *P. boliviana* in other analyses; more work required in order to determine correct placement of this warbling-finch, and if similarity to *P. torquata* is due to convergence. Monotypic.

Distribution. SW Ecuador (SW Manabí, W Guayas, also rarely S Loja and S El Oro), and coastal slope of Peru from Tumbes S to Arequipa.

Descriptive notes. 13·5 cm; one male 16·5 g. A small, compact warbling-finch with relatively short and triangular bill. Male has grey crown, black stripe on sides of crown meeting centrally on forehead, long white supercilium, contrasting black mask, and broken white eyering; nape and side of head behind black ear-coverts grey, turning brownish-grey on back, rump and uppertail-coverts; tail blackish, extensive white on inner webs of outer rectrices (folded tail looks largely white from below); upperwing grey, median coverts tipped pale grey, greater coverts tipped whitish-buff (creating one or two pale wingbars), tertials with pale brown fringes; clean white chin, throat and underparts accented by broad black breastband, which narrows at centre of breast (in fresh plumage, feathers of breast side tipped brownish), flanks pale grey, belly and vent white (white often intruding in inverted V-shape into black breastband), cinnamon patch on largely white crissum; iris dark brown; bill blue-grey, black culmen and tip; legs dull pinkish. Female is much duller than male, brown above and streaked, face pattern similar to male's, but mask dull grey-brown (rather than black), and below off-white with obscure pale brown streaks, lacking cinnamon on crissum; wings brown with buffy wingbars, buffy edges of flight-feathers, greyish-brown shoulder (lesser upperwing-coverts), tail brownish, white pattern on inner webs of outer rectrices as on male; bill dull pinkish, often with blackish tip, legs brownish-pink. Immature is similar to female, but duller and more streaked. Voice. Loud, vigorous whistled song "twik, swick-sweeu", reminiscent of that of Golden-billed Saltator (*Saltator aurantiirostris*). Call a low gruff "djer-djer".

Habitat. Desert scrub, particularly with dense shrub layer and near water; riparian scrub. Found also in agricultural areas with scattered bushes, low trees or hedgerows. Sea-level to 1000 m, sometimes to 2500 m.

Food and Feeding. Feeds largely on invertebrates. Forages both in low trees and on or near ground in dense vegetation. Generally in pairs; does not associate particularly with other members of family.

Breeding. In Ecuador, egg dates mid-Feb to mid-May, following onset of rainy season, but song activity during dry season (Jul–Sept); single-brooded, but some attempt second brood, particularly in wetter years. Clutch 3–4 eggs. No other information.

Movements. Appears to move depending on rainfall patterns; in SW Ecuador, numbers increase at start of rainy season (Jan), although some may be present in area throughout year.

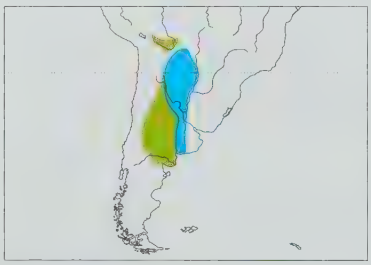
Status and Conservation. Not globally threatened. Locally common, abundant on I de la Plata (Ecuador); scarce at S end of range in Peru. No significant threats known.

Bibliography. Armani (1985), Lougheed *et al.* (2000), Marchant (1959), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Trollope (1984).

219. Ringed Warbling-finch

Poospiza torquata

French: Chipiu sanglé **German**: Bandammerfink **Spanish**: Monterita Acollarada



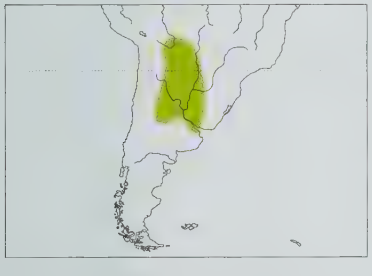
Taxonomy. *Emberiza torquata* d'Orbigny and Lafresnaye, 1837, Sicasica, La Paz, Bolivia.

New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within this genus, is sister to that clade. A recent molecular-genetic study indicated that present species belonged to a clade that included also *P. alticola*, *P. erythrophrys* and *P. melanoleuca*, and was rather distantly related to very similar-looking *P. hispaniolensis*; more work needed to confirm that plumage similarity to last-mentioned is due to convergence. Of particular interest is that cytochrome *b* sequences of the two races of present species differed by as much as 4·4% (equivalent to that of undisputed species included in the study); this suggests that *pectoralis* may be a cryptic species, although further comparative data on song, behaviour and plumage differences is necessary before treatment as separate species can be considered. Two subspecies recognized.

Subspecies and Distribution.

P. t. torquata (d'Orbigny & Lafresnaye, 1837) – C Bolivia (highlands of La Paz, Cochabamba, W Santa Cruz and N Chuquisaca).

P. t. pectoralis Todd, 1922 – breeds N & C Argentina from E Salta, Jujuy and Formosa S to Mendoza, La Pampa, NE Rio Negro and W Buenos Aires; non-breeding also N to SE Bolivia (Tarija) and W Paraguay (Alto Chaco region).



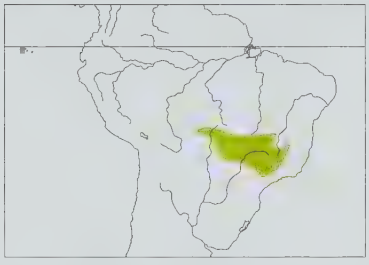
Descriptive notes. 12–14 cm; 10–13·2 g. A slim warbling-finch with small bill with rather rounded culmen. Male nominate race has crown grey with blackish lateral stripe, blackish-grey mask bordered above by long white supercilium, small white subocular crescent; nape and side of head posterior to black ear-coverts grey, upperparts to rump and uppertail-coverts grey; tail blackish, extensive white on outer three feather pairs, outermost rectrix entirely white on outer web and with terminal half of inner web white, white decreasing in extent on next two feathers; upperwing grey, white patch on outer median and greater upperwing-coverts, extending to pale bases and fringes on outer primaries, grey fringes on tertials; clean white chin and throat, broad black breastband narrowing at centre of breast, flanks pale grey, belly and vent white, white intruding as inverted V-shape into black breastband, crissum cinnamon; iris dark brown; bill blackish; legs dusky. Female is very like male, but slightly duller in colour saturation, with narrower and paler breastband. Immature is similar to female, but breastband is weak and brownish. Race *pectoralis* is substantially smaller than nominate, has broader black breastband, more white on outer rectrices, and blacker face, often also paler, nearly whitish edges of tertials. Voice. Song of nominate race a series of c. 5 notes given in repeated pattern,

sometimes altered with slightly different note order, or with inserted note that breaks up monotonous repetition, sweet and cheerful, each phrase often ending in a more exclamatory note, "suu-wee sveew swee-Chup...". Song of race *pectoralis* has sibilant timbre and faster delivery, "tsiu-tseetu tsiu-tseetu trrrp...". Call (nominate) a high "zip", sometimes in series.
Habitat. Arid woodlands, *chaco* thorn-forest, Monte Desert (both shrublands and open woodlands), often on sandy soil; also deciduous scrub and forest. In Bolivia, open Andean dry forest, in dry to semi-humid secondary scrub and on degraded open *Dodonaea* slopes, in Cochabamba also locally in open *Polylepis* woodland; arid slopes in intermontane valleys in Santa Cruz. Sea-level to 1800 m.
Food and Feeding. During breeding season feeds largely on arthropods (in contrast to sympatric *P. ornata*, which relies on grass seeds); seeds become more important in diet during autumn and winter. Forages mainly in shrubs and short trees, exploiting a broad range of species throughout year, most commonly *Prosopis flexuosa*. Gleans insects from leaves, often in excited almost parulid-like manner; also takes grass seeds by perching on thicker stems while extracting seeds. Found in pairs and in family groups; joins mixed-species foraging flocks of New World sparrows and finches during non-breeding season.
Breeding. Nominate race in breeding condition Jan–Feb; start of egg-laying from mid-Oct to late Dec in drier years, extended to early Feb in wetter years; some evidence of two broods. Nest a cup of grass stems and rootlets, smaller but deeper than that of *P. ornata*, lined with hairy achenes of composites, hair and feathers, placed at average of 1 m from ground in plant (mean height of plants used 1·8 m); of 109 nests in Mendoza (Argentina), 92% in chañar (*Geoffroea decorticans*) or in zampa (*Atriplex lampa*), and common creosote bush (*Larrea divaricata*) avoided. Clutch 3–4 eggs, pale blue with brownish to reddish blotches and scrawls. No other information.
Movements. Nominate Andean race mostly sedentary; variation in abundance, from uncommon in austral summer to fairly common in austral winter, at Tambo (Santa Cruz) suggests some seasonal altitudinal movements. Lowland *pectoralis* resident in some areas, partially migratory (moving N & E in austral winter) in others; at one well-studied site in Argentina (Ñancuñan, in Mendoza), annual abundance varies from year to year; also, records from Paraguay only Apr–Sept, during austral winter, and recorded in Bolivian Chaco only as non-breeding winter resident.
Status and Conservation. Not globally threatened. Fairly common to common throughout its extensive range.
Bibliography. Armani (1985), Blendinger (2005a), Blendinger & Ojeda (2001), Canevari *et al.* (1991), Hayes (1995), Lougheed *et al.* (2000), Mezquida (2004), Mezquida & Marone (2003), Milesi *et al.* (2008), de la Peña (1989), Ridgely & Tudor (1989), Storer (1989b).

220. **Black-capped Warbling-finch**
Poospiza melanoleuca

French: Chipiu à capuchon **Spanish**: Monterita Cabecinegra
German: Schwarzkappen-Ammerfink
Other common names: White-breasted Warbling-finch; Grey-and-white Warbling-finch (when treated as conspecific with *P. cinerea*)

Taxonomy. *Emberiza melanoleuca* d'Orbigny and Lafresnaye, 1837, Chiquitos, Bolivia.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within this genus, is sister to that clade. A recent molecular-genetic study indicated that present species belonged to a clade that included also *P. alticola*, *P. erythrophrys* and *P. torquata*. Until recently it was treated as conspecific with *P. cinerea*. Monotypic.
Distribution. SE Bolivia (Cochabamba and Santa Cruz S to E Chuquisaca and E Tarija), W & C Paraguay (except extreme E Alto Paraná), N & NC Argentina (Salta, Jujuy and Formosa S to San Luis, C Cordóba and extreme N Buenos Aires), W Uruguay and SE Brazil (extreme W Rio Grande do Sul).

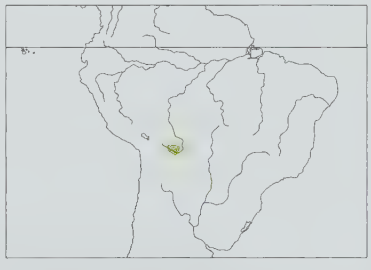


Descriptive notes. 13 cm; 9–15 g. A small, compact and relatively short-tailed warbling-finch with small, triangular bill. Male has black hood from forehead to nape, cleanly demarcated by white submoustachial and malar area; upperparts blue-grey; tail blackish, white outer feathers; upperwing blackish, blue-grey shoulder, blue-grey edging on upperwing-coverts and flight-feathers; throat and underparts gleaming white, except for pale grey flanks; iris reddish; bill black, sometimes grey base of lower mandible; legs black. Female has less extensive black cap and may appear duller in direct comparison with male; iris not so bright as male's. Immature has black on head restricted to lores and side of face, at most. Voice. Song a high-pitched and monotonously repeated three-part (sometimes four-part) "twasut tsee twaas". Calls include muffled "chuf-chuf-chuf", singly or in series, when excited; also an ascending, metallic-sounding "pifzzztt"; when flock alarmed, birds excitedly give high-pitched calls and "chuf" calls, developing into a sputtering chatter.
Habitat. Chaco woodlands, *espinal* (thorny woodlands), savanna and shrub-forest; prefers dense vegetation.
Food and Feeding. Seeds, fruits and flowers; may also take arthropods, particularly during breeding season. Forages largely in shrubbery, scrub and small trees. Tends to be found in small flocks, possibly family groups.
Breeding. Nests found during Oct–Feb In Argentina; nest-building in mid-Nov in Brazil. Nest a cup made from dry grass and vegetable fibres, sometimes lichen, lined with much finer material such as wool, placed low down, usually within 1 m of ground, in thick herbaceous vegetation or in low shrub or tree. Clutch 3–4 eggs, white or pale greenish with black scrawls and blotches, these particularly around wide end. Nests known to be parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Relatively common, sometimes abundant; widespread. No known threats.
Bibliography. Armani (1985), Belton (1985), Canevari *et al.* (1991), Cornet (2002), Hennessey *et al.* (2003), Lougheed *et al.* (2000), de la Peña (1987, 1989), de la Peña & Pensiero (2003), Storer (1989b).

221. **Cinereous Warbling-finch**
Poospiza cinerea

French: Chipiu à tête cendrée **German**: Graukopf-Ammerfink **Spanish**: Monterita Cinérea
Other common names: Grey-and-white Warbling-finch (when treated as conspecific with *P. melanoleuca*)

Taxonomy. *Poospiza cinerea* Bonaparte, 1850, Minas Gerais, Brazil.
New molecular data indicate that genus forms a clade with the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*, and that *Compsospiza*, which often subsumed within this genus, is sister to that clade. Until recently this species was treated as conspecific with *P. melanoleuca*. Monotypic.
Distribution. S interior Brazil from C Mato Grosso E to S Goiás, Minas Gerais and N São Paulo.



Descriptive notes. 13 cm; 8·4–15·2 g. A small, compact and relatively short-tailed warbling-finch with small, triangular bill. Male has forehead, crown and nape grey, contrasting blackish mask (lores and most of ear-coverts) cleanly demarcated on lower edge by white moustachial and malar area; upperparts blue-grey; tail blackish, white outer feathers; upperwing blackish, blue-grey shoulder and blue-grey edging on upperwing-coverts and flight-feathers; throat and underparts gleaming white, except for pale grey flanks; iris deep chestnut; bill black, sometimes grey base of lower mandible; legs black. Female has less extensive and less dark mask, may appear duller in direct comparison with males; iris not so bright as male's. Immature has head washed brown. Voice. Song apparently unrecorded; high-pitched lively warbles described, possibly song. Call a muffled "chupf", sometimes in series.
Habitat. Occupies *cerrado* woodlands, open dry woodlands and scrub; thought to like fairly open wooded habitats. Also *campo rupestre* habitats, favouring orchards, old pastures and even burnt-over scrub. Mainly 600–1400 m.
Food and Feeding. No information.
Breeding. Breeding record in Sept. Has been known to host Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Sedentary.
Status and Conservation. VULNERABLE. Uncommon to rare, and locally distributed. Suspected to have suffered rapid and continuing decline owing to reduction in area of suitable habitat. Recent records from eight sites in Minas Gerais, four in Goiás, and one (near Brasília) in Distrito Federal. Not recorded in Mato Grosso since 1904 and none in São Paulo since 1901, and possibly extinct in these regions. Although this species has probably always been rather scarce, extent of habitat loss suggests that it has probably undergone significant reduction in numbers. Since c. 1950 much of the *cerrado* habitat has been destroyed or severely altered by combined effects of grazing, invasive grasses, annual burning, and conversion to eucalypt (*Eucalyptus*) plantations, soybean-growing and pastures for exportable crops (encouraged by government land reform). On the other hand, recent reports suggest that it is able to tolerate, and perhaps even favour, degraded areas, perhaps indicating that it is more numerous than previously believed; possibly semi-nomadic in response to fire succession, and seems to be extending its range towards degraded areas in E Minas Gerais. This species is protected under Brazilian law; it occurs in various reserves and parks, including Das Emas National Park, Brasília, Serra do Cipó and Chapada dos Veadeiros National Parks, Peti Reserve, Serra do Brigadeiro State Park and Mangabeiras Park.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Lopes *et al.* (2010), Lougheed *et al.* (2000), Ridgely & Tudor (1989), Sick (1993), Stattersfield & Capper (2000).

Genus *COMPSOSPIZA* Berlepsch, 1893

222. **Cochabamba Mountain-finch**
Compsospiza garleppi

French: Chipiu de Cochabamba **Spanish**: Monterita de Cochabamba
German: Garleppammerfink
Other common names: Slate-and-rufous Warbling-finch

Taxonomy. *Compsospiza garleppi* Berlepsch, 1893, Vacas, Cochabamba, Bolivia.
Genus often subsumed in *Poospiza*, but recent molecular data indicate that it is sister to a clade formed by latter genus and the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*. This species may form a superspecies with *C. baeri*, and has been considered conspecific. Monotypic.
Distribution. Cochabamba and adjacent N Potosí, in C Bolivia.

Descriptive notes. 17–18 cm. Rather large and heavy finch with long tail, but stocky and thick-set body. Most of head and upperparts are leaden grey, with bold orange-rufous forehead, supercilium and crescent below eye; tail and upperwing dark grey, lacking any obvious pattern; entirely orange-rufous below, slightly paler on belly; iris deep brown; bill blackish, lower mandible paler, blue-grey; legs dusky. Sexes alike. Juvenile is greyish-brown above, throat and breast dusky, streaked buff, belly buffy and narrowly streaked dusky. Voice. Males has two song types: one given near nest, and while female building, a series of 3–5 stereotypical soft notes, generally increasing slightly in pitch, including high-pitched introductory note followed by warbled whistles, "tzeet twooo–swee...tzeet twoo–swee...", appears not to have particularly territorial function (playback does not elicit strong response from birds); second song type less common, a series of whistles and intervening pauses, but covering much wider range of frequencies, more variable, and including broad-frequency buzzy note, this song eliciting strong aggressive response if played back to pairs. Call a high-pitched, soft ascending "sweep".
Habitat. Humid inter-Andean valleys with moist ravines near tree-line, in narrow transitional zone between dry Valle and *puna* zones. Usually in mixed agricultural land with native shrubs; includes brushy canyons and slopes, from dense shrubbery to more open scrub at edge of bunch-grass, also *Polylepis* woodland and alder (*Alnus*) thickets. At 2700–4200 m, usually 3000–3800 m.

Food and Feeding. No information on diet. Forages low in shrubbery and on ground.
Breeding. Breeds in rainy season, Jan–Apr; generally single-brooded, but will renest if first attempt fails. Nest built by female, male helping rarely (often singing nearby), a well-formed cup built mainly from dry grasses, soft lining of green grass stems and animal hair, covered externally with mosses or bark of *Polylepis*, usually placed on fork of branch low down in shrub (*Gynoxys*, *Baccharis*, *Berberis*, *Polylepis besseri*) or well hidden in pampas grass (*Cortaderia*) or in ground bromeliad (*Puya*). Clutch 1 or 2 eggs, off-white with dense brownish spotting; incubation by female, period 14 days; chicks fed by both parents, nestling period 18 days.
Movements. Sedentary.
Status and Conservation. ENDANGERED. Uncommon to rare in Cochabamba; locally frequent in Potosí. Estimated global population in 1990s between 400 and 4000 individuals, and declining. Rate of current population decline thought to be 10–19% over 10 years. Formerly thought to be restricted to Cochabamba, but discovered in Potosí in 2005, with additional site records in latter department in 2008. Fieldwork in 2009 suggests that this species is tolerant of small-scale habitat alteration and destruction, but seems to be absent from highly degraded areas devoid of native vegetation. It requires a mosaic of habitats, of which *Polylepis* is one (contrary to earlier reports, it is not a *Polylepis* specialist); it fares well in agricultural areas and other sites influenced by humans, but only so long as native shrubbery is present, and is absent from heavily modified areas or those lacking native shrubs. It has been suggested that the replanting of a variety of native shrub species could be the best management strategy for this species. Occurs in Tunari National Park, in Cochabamba; a sizeable proportion of this park, however, has already been converted to pine (*Pinus*) stands, and its future protection is by no means assured.
Bibliography. Balderrama (2006, 2009), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Huanca *et al.* (2009), Lougheed *et al.* (2000), Ridgely & Tudor (1989), Stattersfield & Capper (2000).

223. Tucuman Mountain-finch

Compsospiza baeri

French: Chipiu du Tucuman **German**: Baerammerfink **Spanish**: Monterita de Tucumán

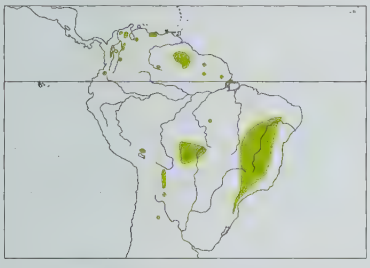
Taxonomy. *Buarremon baeri* Oustalet, 1904, Lagunita, Tucumán, Argentina.
Genus often subsumed in *Poospiza*, but recent molecular data indicate that it is sister to a clade formed by latter genus and the tanager (Thraupidae) genera *Hemispingus* and *Thlypopsis*. Present species may form a superspecies with *C. garleppi*, and the two have been considered conspecific. Monotypic.
Distribution. Extreme S Bolivia (S Tarija) and Andes of NW Argentina from Jujuy, Salta, Tucumán and Cajamarca S to NE & W La Rioja.
Descriptive notes. 16·5–18 cm; 31·5–34·5 g. Relatively large and heavy finch with long tail, but stocky and thickset body. Male has most of head and upperparts grey, bold orange-rufous forehead, supercilium and crescent below eye; tail and upperwing dark grey, lacking any obvious pattern;

throat and upper breast orange-rufous, lower breast, flanks and upper belly grey, lower belly and vent palest grey to whitish, crissum orange-rufous like throat; iris muddy brown to deep reddish-brown; bill blackish above, paler blue-grey below; legs greyish. Female is very similar to male, but extent of rufous on throat and breast smaller. Juvenile is grey-brown above, streaked indistinctly on crown, and pale brown with darker streaks below. Voice. Song is a series of short whistles, differing slightly in frequency, "swit-jeet-siit-swop-sweet-swit...", extremely similar to that of *C. garleppi*. Contact call a high "sip" note; also a sharper repeated "tip-tip...tip...tip-tip", likely an alarm call.
Habitat. Mosaic of *puna* grassland with adjacent shrubby woodland of alders (*Alnus*), as well as *Polylepis* and other shrubs. In non-breeding season may be found also in willow (*Salix*) thickets by streams, and may descend to gardens in towns such as Tafi del Valle. At 2500–3100 m; down to 1200 m in winter in S part of range.
Food and Feeding. Individual seen carrying a grasshopper (Orthoptera); probably also feeds on seeds. Forages on ground and low in shrubbery. Often in pairs; joins mixed-species foraging flocks in non-breeding season.
Breeding. Birds with enlarged gonads in Dec, and main season Jan–Mar, with egg dates in late Jan and early Feb and fledglings in Apr. Nest placed in dense tussock of *Stipa* or *Festuca* grass. Clutch 2–3 eggs, white with purplish-brown spotting. No other information.
Movements. Largely sedentary; minor movements downslope in winter.
Status and Conservation. VULNERABLE. Generally uncommon. Has rather small and fragmented range, within which estimated global population of only a few thousands, probably 5000–10,000 individuals. Recently (in 1999) found in extreme S Bolivia, where two individuals noted at Estancia Waykhu, in S Tarija. Occurs at low densities, 0·02–0·03 birds/km² during breeding season in Tucumán, increasing to 0·24 birds/km² during non-breeding season, at 2600–3100 m elevation. Recorded at comparatively few sites in NW Argentina: Termas de Reyes (Jujuy), Chicoana, R Tranca and R Peña Negra (Salta), Sierra de Medina and Sierra del Aconquija (Tucumán), Sierra de Ambato (Catamarca), and Sierra de Velazco and Banda Florida (La Rioja). Natural habitat in the region has been destroyed by human settlement and accompanying goats and cattle; also, expanding agriculture threatens some sites, and fires in nearby grasslands could spread into ravines occupied by this species. In Tucumán, occurs in El Infiernillo Reserve (specially created for this species) and recorded recently at Campo de los Alisos National Park; recent records also from Cordillera de Sama Biological Reserve, in S Bolivia.
Bibliography. Bodrati (2005), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Lougheed *et al.* (2000), Pearman (2001), Peris (1997), Ridgely & Tudor (1989), Stattersfield & Capper (2000).

PLATE 61 ➤

PLATE 61

inches 2
cm 5



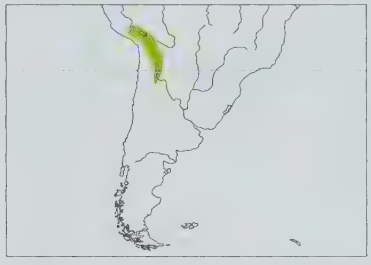
Genus *SICALIS* Boie, 1828

224. Stripe-tailed Yellow-finch

Sicalis citrina

French: Sicale citrin **German**: Zitronengilbammer **Spanish**: Chirigüe Citrino

Taxonomy. *Sycalis citrina* Pelzeln, 1870, Jaguaraíba, Paraná, Brazil.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Races poorly differentiated, and species perhaps better treated as monotypic. Three subspecies currently recognized.
Subspecies and Distribution.
S. c. browni Bangs, 1898 – W & N Colombia (Santa Marta, Antioquia, Cauca, Santander, Norte de Santander and Cundinamarca), Venezuela (Sierra de Perijá, coastal mountains, Trujillo, Mt Duida and tepuis of Bolívar and Amazonas) and adjacent tepui region of Guyana, Suriname and N Brazil (locally E to Amapá).
S .c. occidentalis Carriker, 1932 – SE Peru (Puno) and NW Argentina (Salta, Tucumán and E La Rioja).
S. c. citrina Pelzeln, 1870 – E Brazil (S Pará, Goiás and Piauí S to E Mato Grosso and Paraná).
Also occurs (probably *occidentalis*) in much of Bolivia (La Paz, Cochabamba, Santa Cruz, Chuquisaca and Tarija), and (probably nominate) in NE Bolivia (Beni) and perhaps adjacent Brazil.



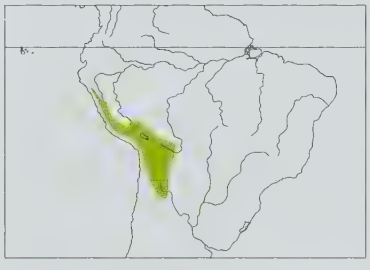
Descriptive notes. 11 cm; 10·7–12·9 g. A small, stocky and compact yellow-finch with relatively short and deep bill; head often looks squarish in shape. Male nominate race has head mostly plain yellow with olive wash; upperparts olive-yellow with fine darker streaking (except on rump); upperwing brownish-grey, yellow edging on upperwing-coverts and flight-feathers; tail dusky, white terminal half on inner web of outer two rectrices; below, entirely yellow with slight olive cast; iris dark brown; bill blue-grey, darker culmen; legs pink to flesh-coloured. Female is brownish above, face dull and lacking pattern other than pale eye-crescents, finely streaked from crown to rump; pale yellow below, streaked brown on breast and flanks; wings brownish, paler (but not bright yellow) edging on upperwing-coverts and flight-feathers; tail has white patterning like that of male, but somewhat reduced; bill dusky, legs dull pink. Juvenile is like female, but browner and more streaked, including face; immature like female, but streaking on breast and flanks more extensive and coarser. Race *browni* is smaller than nominate, has shorter tail and more slender bill, but differences very slight, ear-coverts possibly a little greener, underparts a purer yellow; *occidentalis* is similar to nominate, but brighter yellow below, breast with narrow sharply defined streaks. Voice. In much of range, male song, given from perch and in flight display, begins with a series of chattering notes and ends in a trill, quite musical, "weet-twu, chu'u'u'u'u'u'u" or "wit-tr-tr-tr-tr-t-t-t-t-t-t"; songs in Brazil (nominate race) more complex, "weeta-weeta twi-chuu twi-chuu twi-chuu", may be reminiscent of a siskin (*Carduelis*). Call a simple "chup".
Habitat. Various types of grassy and open habitats. Grasslands and savanna, including highland grasslands in Colombia; also edges of marshes in grassy areas. In Bolivia in *campo cerrado*, sparsely vegetated rocky outcrops that stand out in flat shrubby terrain; in NW Argentina found in meadows interspersed with montane forest patches, at c. 1400 m. Occurs from tropical to temperate zones; 400–2800 m, rarely to 3700 m.
Food and Feeding. Diet a mix of seeds and arthropods, latter mostly during breeding season. Seems especially attracted to seeding grasses, and will cling to stems in order to reach seeds; feeds also on seeds on ground. Forages in pairs and in small flocks.
Breeding. In E Brazil breeding begins after start of rainy season (Dec–May), most often Jan–Mar; in N Colombia, birds in reproductive condition in Jun (E Andes), and copulation observed in Jul and juveniles in Aug (Cundinamarca); birds in breeding condition in Jun in Peru; males performing flight displays in late Dec in N Argentina (Salta). Male performs flight display, rising to 6 m off ground, while singing. Nest an open cup, placed in small shrub, ferns or sometimes in dense grass clump, average height from ground 30 cm. Clutch (Brazil) 2–3 eggs, pale turquoise with brown markings, these more densely distributed around wide pole; incubation period 12 days; nestling period 13 days.
Movements. No information; possibly somewhat nomadic.
Status and Conservation. Not globally threatened. Uncommon to fairly common, and very local. Very patchily distributed, but occurs over huge range and, unusually when range so fragmented, at wide variety of elevations.
Bibliography. Armani (1985), Carriker (1931), Dunning (2008), Fjeldså & Krabbe (1990), Gressler (2008), Maillard *et al.* (2008), Pearman (2001), Renssen (1974), Restall *et al.* (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Todd & Carriker (1922), de Vasconcelos & Endrigo (2008).

225. Puna Yellow-finch

Sicalis lutea

French: Sicale jaune **German**: Punagilbammer **Spanish**: Chirigüe Puneño

Taxonomy. *Emberiza lutea* d'Orbigny and Lafresnaye, 1837, Pampas d'Oruro [= Oruro], Bolivia.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Monotypic.
Distribution. SE Peru (highlands from SE Cuzco and NE Arequipa E to Puno and Tacna), Bolivian highlands (La Paz, Cochabamba, Oruro and Potosí and W Tarija), extreme NE Chile (Visviri area of Arica–Parinacota) and NW Argentina (dry *puna* of Jujuy and Salta).



Descriptive notes. 13·5–14 cm; 14·6–17·9 g. A stocky and pot-bellied, short-tailed yellow-finch with deep, short bill with straight culmen. Male is golden-yellow throughout, with little patterning: head yellow with slight green wash, pale yellow eyering; upperparts plain yellow-green, marginally greener than head, rump to uppertail-coverts slightly brighter yellow than back; below, plain bright lemon-yellow, flanks washed olive; upperwing dusky, feathers broadly edged yellow (wing appears essentially yellowish), tertials with contrasting whitish edges; tail dusky, outer rectrices broadly edged yellow (only centre of tail appears dark on perched bird); iris dark brown; bill blackish, grey base of lower mandible; legs flesh-coloured to blackish. Female is only slightly duller than male. Juvenile is brownish-olive and streaked throughout above, buffy below; immature has head essentially greenish-yellow, pale yellow or whitish eyering and greyish lores, back pale brownish-yellow and indistinctly streaked, brighter yellow on rump and uppertail-coverts, yellow with olive wash below, flanks greyish, wings and tail dusky, broad yellow edges on lesser and outer median and greater upperwing-coverts, yellow edges on primaries and base of secondaries, tertials distinctly white-fringed, noticeable yellow edging on outer rectrices. Voice. Song "twu trrrr whipa-whipa trrr whipa-whipa tuii trrr", slower than that of other highland members of genus and notes often repeated. Calls include rich "tchew" or "tjup", sometimes doubled as "tjup-tjup", sometimes shortened as "zit"; also a mewing "meluu".
Habitat. Open country in *puna*, dry grassland and open scrubby sites, usually in flatter sites, rather than on slopes; commonly in broad river valleys, particularly if nesting banks available. Unlike e.g. *S. olivascens* and *S. uropigyalis*, is not attracted to adobe houses and villages. At 3800–4500 m.
Food and Feeding. No information on diet. Forages on ground, in small flocks of 4–20 individuals; tends not to mix with other members of genus.
Breeding. Eggs in Feb in Argentina (Jujuy) and juveniles in Apr in Bolivia (La Paz). May be somewhat colonial, and uses nest-sites or other holes for roosting throughout year. Nest a cup 2 cm deep and 14 cm in diameter, of dry grass, built in earthen bank or cliff, the birds making a hole and excavating a tunnel; one nest in Jujuy was in tunnel 1·2 m deep, with entrance hole 1·5 m from ground in earthen bank; in NW Argentina reported also as using abandoned nests of furnariids and cavities made in cacti by White-fronted Woodpecker (*Melanerpes cactorum*). Clutch 3–4 eggs, white and unspotted. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally common. Occurs in several national parks and other protected areas in Bolivia.
Bibliography. Armani (1985), Blendinger (1999), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Hoy (1980), Olrog & Navas (1961), de la Peña (1987), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

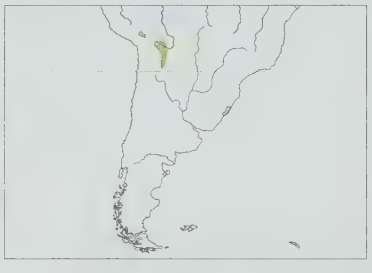
226. Bright-rumped Yellow-finch

Sicalis uropigyalis

French: Sicale à croupion jaune **German**: Goldbürzel-Gilbammer **Spanish**: Chirigüe Culigualdo

Taxonomy. *Emberiza uropigyalis* d'Orbigny and Lafresnaye, 1837, Bolivia.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Proposed race *connectens*, described from upper Urubamba Valley (Cuzco), in S Peru, doubtfully distinct from nominate, with which synonymized. Species name often altered to "*uropygialis*", but this is an unjustified emendation. Two subspecies recognized.
Subspecies and Distribution.
S. u. sharpei (Berlepsch & Stolzmann, 1894) – W & C Peru from Cajamarca S to Junín.
S. u. uropigyalis (d'Orbigny & Lafresnaye, 1837) – SE Peru (Puno) and highlands of Bolivia S to N Chile (Arica–Parinacota, Tarapacá and Antofagasta) and NW Argentina (Salta, Jujuy and Tucumán).

Descriptive notes. 13–14 cm; 21–24·4 g. A stout and long-bodied, relatively short-tailed yellow-finch with very long wings, showing long primary extension on perched bird; bill stout, but relatively long and pointed, with slightly curved culmen. Male nominate race has unstreaked yellow head and nape, well-demarcated and contrasting grey mask (lores and ear-coverts), whitish eye-crescents above and below eye; mantle and back blue-grey, contrasting with yellowish head and yellow lower back to uppertail-coverts; yellow below, with well-demarcated grey flanks; upperwing blue-grey, in fresh plumage with silvery-white edges on primaries; tail feathers blackish with light blue-grey edging, becoming yellower basally; iris dark brown; bill blue-grey, dark culmen; legs dull pinkish. Female is similar to male, but yellow areas duller, and grey areas more brownish-grey; yellow on head less extensive, with grey-brown hindcrown and nape, grey of flanks more extensive, reaching side of breast and continuing to vent, and sometimes to crissum (which otherwise dull yellow); brownish-grey upperparts may show indistinct streaking. Juvenile is duller, more brownish, than adult, and strongly streaked above and below, tertials with distinct warm brown fringes; immature male duller yellow below than adult, grey of plumage with brownish tone, obscurely streaked on crown and back, wing-coverts edged buffy white; immature female like adult, but breast obscurely streaked, and yellow in plumage not so bright. Race *sharpei* lacks grey on flanks of male, and has shorter bill, more extensive yellow on rump. Voice. Song loud and twittering, lasting 2–4 seconds, irregularly ascending and descending, "de de de de de dit chittit", last notes accentuated, quite variable both in length and in sweetness, some songs canary-like, others harsher and slower; more work needed in order to determine if different song types are given



On following pages: 227. Citron-headed Yellow-finch (*Sicalis luteocephala*); 228. Greater Yellow-finch (*Sicalis auriventris*); 229. Greenish Yellow-finch (*Sicalis olivascens*); 230. Patagonian Yellow-finch (*Sicalis lebruni*); 231. Orange-fronted Yellow-finch (*Sicalis columbiana*); 232. Saffron Finch (*Sicalis flaveola*).

by single males or if some differences are geographical. Flight call a soft, sweet doubled note, "wee-weet".
Habitat. High *puna* grasslands, including grass–shrub mixture on slopes; may forage in moist *bofedal* wetlands ("cushion bogs"), particularly if adjacent to drier grasslands or rocky and brushy slopes; often drawn to small Andean villages or adobe houses. At 2500–4800 m.
Food and Feeding. Few data on diet; presumably mainly seeds and other vegetative material, though a shift to arthropods in breeding season likely. Forages on ground. Generally in pairs and in small flocks; in non-breeding season, particularly during times of high snowfall, can form large flocks of up to 500 individuals. May mix with other high-elevation finches such as various *Phrygilus* species and *Diuca speculifera*; sometimes forages with *S. olivascens* and with *S. luteocephala*, both of which generally found at lower elevations than present species.
Breeding. Adults feeding nestlings from Apr to early Jun in Peru, fledglings in Apr in Bolivia (Cochabamba) and nests in Jan–Feb in NW Argentina. Nest a cup of dry grasses, 12 cm in diameter, placed in hole in bank or, most often, in wall of adobe building or under roof; one nest in Argentina (Jujuy) was at end of tunnel c. 30 cm deep in mud wall, with entrance hole 30 cm above the ground. Clutch 4 eggs, white with grey and chestnut speckles, these concentrated at wide end. No other information.
Movements. Apparently sedentary; may perform local or elevational movements in direct response to periods of high snowfall.
Status and Conservation. Not globally threatened. Often fairly common to common. This species has a large range, and adapts well to human presence, being often found near villages or isolated dwellings in *puna*. No particular problems in terms of habitat loss. Occurs in five protected areas in Bolivia.
Bibliography. Armani (1985), Dunning (2008), Fjeldså & Krabbe (1990), Johnson & Goodall (1967), de la Peña (1987), Ridgely & Tudor (1989), Roe & Rees (1979).

227. Citron-headed Yellow-finch
Sicalis luteocephala

French: Sicale à tête jaune **German**: Graunacken-Gilbammer **Spanish**: Chirigüe Cabecigualdo

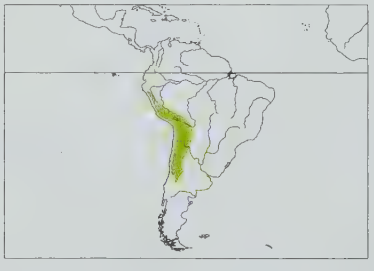
Taxonomy. *Emberiza luteocephala* d'Orbigny and Lafresnaye, 1837, Chuquisaca; error = Totora, Cochabamba, Bolivia.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Monotypic.
Distribution. Andes of Bolivia (Cochabamba, W Santa Cruz, Chuquisaca, Potosí and Tarija) and extreme N Argentina (Jujuy).

Descriptive notes. 13–14 cm. Moderately long-tailed yellow-finch, bill short and with slight curve on culmen; wings much shorter than otherwise similar *S. uropigyalis*. Male has yellow face with narrow darker eyeline, contrasting grey hindcrown and nape; upperparts solid grey to tail base; yellow of face continues to throat and centre of breast, with side of breast and flanks grey, grey extending to vent and isolating yellow crissum; upperwing greyish, grey shoulder (lesser upperwing-coverts) may be yellow-washed when plumage fresh, yellow edging present on on outer greater and median coverts, also outer secondaries, and primaries (creating yellow flash on folded wing), tertials edged pale grey or whitish; tail grey, yellow edges at base of rectrices; iris dark brown; bill dark bluish-grey; legs pinkish. Female is similar to male, but duller yellow on face and underparts, more brownish-grey on upperparts, flanks paler. Juvenile is still duller than female, pale brownish above, wings edged cinnamon, dull buff throat and breast; immature like female, but orange-yellow base of lower mandible. Voice. Song pleasing and melodic, notes repeated relatively quickly and switching to another series of repeated notes, "chwip-chwip tuup pik-pik-pik-pik tp chipa chwip-chwip chupip chupip chupip tzp tzp pik-pik-pik...", rather like that of a siskin (*Carduelis*); songs may last for many seconds, but rather variable in length, as well as in degree of complexity in terms of number of phrases used. Flight calls include doubled "clep-clep" or "chuck-chuck" during foraging, also a mellow "huit"; other calls include short snarls and chatters, alarm a short "tret".
Habitat. Mosaic of agriculture, grassy patches and highland shrubs on slopes at higher elevations of Andean slopes, below Altiplano and true *puna* grassland zone; not infrequently found near dwellings adjacent to agricultural areas. At 2500–3800 m.
Food and Feeding. No details of diet; probably seeds. Forages on ground, often in open dirt areas near grassland or agriculture, also in sandy or rocky places near areas of scattered shrubs. Found in small single-species flocks of up to 20 individuals; sometimes in mixed-species flocks with *S. uropigyalis*, as well as sierra-finches (*Phrygilus*). Roosts communally, both at breeding cliffs and under bridges, roosting holes sometimes used in middle of day as a refuge from heat.
Breeding. Fledglings recorded in May in Bolivia (Cochabamba). Apparently moderately colonial. Nests in hole in earthen bank. No other information.
Movements. Appears to be sedentary.
Status and Conservation. Not globally threatened. Fairly common to locally uncommon. Adapts well to Andean-style agriculture, and found close to small villages, so not adversely affected by low-impact anthropogenic disturbances. The range of this species does not include any national parks or other protected areas.
Bibliography. Armani (1985), Fjeldså & Krabbe (1990), Hennessey *et al.* (2003), Mazar Barnett, Clark *et al.* (1998), Pearman (1989), Ridgely & Tudor (1989).

228. Greater Yellow-finch
Sicalis auriventris

French: Grand Sicale **German**: Goldbauch-Gilbammer **Spanish**: Chirigüe Grande
Other common names: Yellow-billed Yellow-finch

Taxonomy. *Sycalis auriventris* R. A. Philippi [Krumwiede] and Landbeck, 1864, cordilleras of Santiago, Chile.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). What originally appeared to be an isolated population of *S. lebruni* was recently discovered in EC Argentina, in Sierra de la Ventana (S Buenos Aires); later suggested to be some form of present species; however, nesting habits are quite different from both species (see page 434); further investigation needed. Monotypic.
Distribution. Andes of Chile from Antofagasta S at least to Araucania region, also in Magallanes (Sierra Baguales), and Argentina from at least Mendoza (probably farther N) S to Santa Cruz (Sierra Baguales).

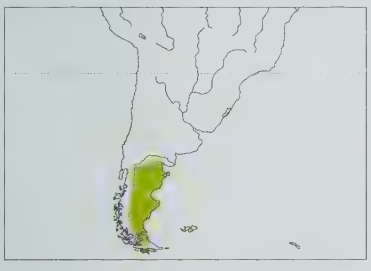


Descriptive notes. 14·5–15 cm; 50–59 g. A pot-bellied, long-bodied yellow-finch with very long wing, showing very long primary projection; longish bill with straight culmen. Male is largely yellow on head, lores slightly darker, slightly paler upper and lower eye-crescents; upperparts yellow with slight olive wash, rump bright yellow (in worn summer plumage shows pencil-thin streaks on mantle); yellow below, brighter than upperparts, with grey restricted to small area on rear flanks; upperwing brownish, olive-yellow wash on shoulder, greyish or silvery edging on greater upperwing-coverts and flight-feathers (edges wear quickly, leaving largely dull brown wing by summer); tail brown with yellow edges; iris dark brown; bill blackish, lower mandible often paler and bluer; legs pinkish. Female is very dull, brownish-grey and unremarkable-looking: plain face, but with pale eye-crescents; most have very restricted yellow, on lower breast and belly and most noticeably on base of tail, otherwise largely unicolored brownish-grey, paler, dull yellowish on throat, and underparts slightly paler than upperparts; back may show some indistinct narrow streaking, and in fresh plumage wings have pale buff fringes, and ear-coverts wash yellow; distinguished from greyish and dull females of *S. olivascens* by much longer wing, longer bill and straighter culmen. Juvenile is similar to female, but with indistinct streaking on breast, and pale cinnamon or warm brown tips on upperwing-coverts (creating two pale wingbars), pale edges on secondaries, lacks yellow at bases of rectrices; immature male duller than adult, more greenish-yellow below, may resemble *S. olivascens*, but longer wing than that species; immature female similar to adult, but more noticeably streaked above, yellow on belly quite restricted, tail with restricted yellow at bases of outer rectrices. Voice. Song an unmusical quavering warble with nasal or buzzy quality, lasting 2–3 seconds, usually notes strung together such that it is difficult to differentiate individual ones, "twiita twiita twet chwet-chwet cho-zheepa". Flight call a soft, nasal "huuit".
Habitat. In much of Chile occupies highest, harshest, driest and rockiest alpine terrain available. Common near houses or villages, often using rocky crevices in buildings for nesting or roosting. Habitat choice varies somewhat with latitude; in Patagonia found much lower down and in moister and grassier sites than the rocky, bare-earth *bofedal* wetland edges preferred in N portion of range. At 2500–4500 m; down to 800 m in Patagonia.
Food and Feeding. Seeds apparently a major component of diet. Forages on ground, both on flat ground and on rocky slopes. In pairs or small flocks; flocks larger early in spring, and particularly when late snowfalls occur, at which time this species concentrates in available patches of foraging habitat.
Breeding. In Santiago region of Chile season Dec–Feb, with juveniles present as early as late Dec and into Feb; may breed slightly later in far S of range. Nest placed in hole or crevice in rocky cliff face or bank, or similar cavity in adobe building or rock wall. Clutch 3 eggs, cream-coloured with chestnut spotting. No other information.
Movements. Appears to be partially migratory, but details require confirmation. S from Santiago breeding areas become uninhabitable during winter owing to high winds, deep snow cover and cold, and birds in this part of range probably migrate N. Downslope movements also occur, and these quite noticeable during late-spring snowstorms, when large flocks found at slightly lower elevations than typically used for breeding.
Status and Conservation. Not globally threatened. Can be common or even abundant locally; uncommon in extreme S of range. Full distribution probably not completely understood.
Bibliography. Armani (1985), Canevari *et al.* (1991), Cozzani *et al.* (2008), Dunning (2008), Fjeldså & Krabbe (1990), Johnson & Goodall (1967), Ridgely & Tudor (1989).

229. Greenish Yellow-finch
Sicalis olivascens

French: Sicale olivâtre **German**: Olivbrust-Gilbammer **Spanish**: Chirigüe Oliváceo

Taxonomy. *Emberiza olivascens* d'Orbigny and Lafresnaye, 1837, La Paz, Bolivia.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Present species may form a superspecies with *S. lebruni*; previously considered conspecific, but differs significantly in plumage, shape, structure and vocalizations. Four subspecies recognized.
Subspecies and Distribution.
S. o. salvini (C. Chubb, 1919) – N Peru from La Libertad S to Huánuco.
S. o. chloris Tschudi, 1846 – W & S Peru (Ancash S to Tacna) and N Chile (Arica–Parinacota S to Coquimbo).
S. o. olivascens (d'Orbigny & Lafresnaye, 1837) – SE Peru (Cuzco and Puno) and W & C Bolivia S to NW Argentina (Salta and Jujuy S to N La Rioja).
S. o. mendozae (Sharpe, 1888) – W Argentina from S La Rioja S to Mendoza and San Luis.



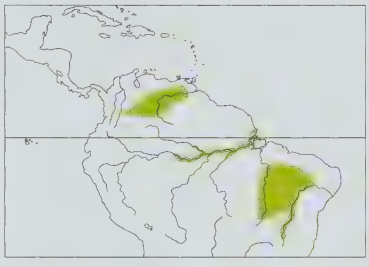
Descriptive notes. 13·5–14 cm; 17·5–24·2 g. A pot-bellied and stocky yellow-finch with relatively short tail, and thick-based, short bill with slightly curved culmen. Male nominate race has greenish-yellow head, lores slightly darker, bright pale yellow eye-crescents; upperparts greenish-grey, rump greenish-yellow; yellow below, brighter than upperparts, with green-vested appearance on breast and flanks; upperwing brownish, greenish shoulder and greenish and grey edging on greater upperwing-coverts and flight-feathers, off-white edges of tertials (edgings wear quickly, leaving largely duller brown wing by summer);

tail brown with yellow edges; iris dark brown; bill mostly greyish, black tip; legs dusky to pink-flesh. Differs from *S. lutea* and *S. auriventris* mainly in less bright appearance, having greenish wash on breast and head. Female is dull, brownish-grey and unremarkable-looking; yellow sometimes restricted to centre of breast and belly, often nearly lacking, and sometimes more extensive, reaching to throat (variable extent of yellow on underparts may be due to feather wear), some also have slight greenish wash above eye, head otherwise largely greyish-brown with distinct pale eye-crescents; in fresh plumage, wing has pale buff fringes and ear-coverts a wash of yellow; some are as greyish and dull as female of *S. auriventris*, but differ from latter in much longer wing, longer bill and straighter culmen. Juvenile is similar to female, but has pale buff tips on upperwing-coverts, pale buff edges on secondaries, and indistinct streaking on breast; immature male similar to female, but underpart feathers tipped buff. Race *chloris* is like nominate, but with shorter tail, larger bill, duller yellow below; *salvini* is similar to previous, but smaller, and with relatively smaller bill; *mendozae* also is is similar, but smaller and duller, with more olive-washed underparts. VOICE. Song 2–4 seconds in duration, a series of rough trills that tend to descend in frequency (or change abruptly to slightly different frequency), sometimes interspersed with more slowly delivered notes that suggest song of House Sparrow (*Passer domesticus*), "chet-chet-chet trrrrrrrrrrr" or "trrrrrrrrrr pzip-tzhip-tzhip zrrrrrruuuuuurrrrr"; lower-pitched trills can at time be reminiscent of voice of a highland furnariid. Call a harsh "tzup" or a sweet "tiip".
Habitat. In N of range found in shrubby *puna*, often on slopes, venturing to edges of villages or highland towns. Farther S associated with dry desert *puna*, particularly near earthen banks or rocky ledges (which provide nesting sites), and found also in extremely arid areas immediately above Absolute Desert zone in Chile. In N Chile and NW Argentina also in highland sites where larger cacti present. At 1500–3800 m.
Food and Feeding. No information on diet; appears to concentrate on foraging for seeds. Forages on ground; in pairs and in flocks of variable size. Possibly daily movements to communal roosts; in N Chile large flocks seen while moving in unidirectional manner during evening, suggesting that they may at times form roosting concentrations.
Breeding. Egg dates Dec–Mar, during wet season, in S Peru, N Chile and N Argentina; fledglings in Jun in Bolivia (Cochabamba), suggesting later breeding season. Tends to be loosely colonial, with several nests in a single bank. Nest made of grasses and hair, one was 8 cm in diameter, placed in crevice or cavity in earthen bank or rocky cliff, sometimes in crack in adobe building or rocky wall; one nest in NW Argentina was at end of tunnel 30 cm deep in earthen cliff. Clutch 4 eggs, whitish, with brown markings concentrated on wide end. No other information.
Movements. Sedentary in much of range. Argentine race *mendozae* partially migratory, most moving N to Salta in winter.
Status and Conservation. Not globally threatened. Common to abundant in most of range.
Bibliography. Armani (1985), Canevari *et al.* (1991), Dunning (2008), Fjeldså & Krabbe (1990), Johnson & Goodall (1967), de la Peña (1987), Ridgely & Tudor (1989), Salvador & Narosky (1984).

230. **Patagonian Yellow-finch**
Sicalis lebruni

French: Sicale de Patagonie **German**: Magellangilbammer **Spanish**: Chirigüe Austral

Taxonomy. *Pseudochloris lebruni* Oustalet, 1891, Misioneros, Santa Cruz, Patagonia, Argentina.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Present species may form a superspecies with *S. olivascens*; previously considered conspecific, but differs significantly in plumage, shape, structure and vocalizations. What originally appeared to be an isolated population of present species was recently discovered in EC Argentina, in Sierra de la Ventana (S Buenos Aires); later suggested to be some form of *Sicalis auriventris*; however, nesting habits are quite different from both species (see page 434); further investigation needed. Monotypic.
Distribution. S Argentina (S from S Rio Negro) and extreme S Chile (from NE Magallanes) S to N Tierra del Fuego.

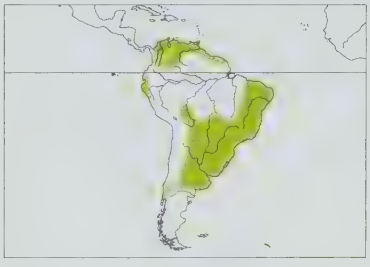


Descriptive notes. 14 cm; 23·1–26·6 g. A relatively large headed yellow-finch with proportionately small and short bill; long-winged, with noticeably long primary extension. Male typically has greenish-yellow forehead and supercilium, greyish hindcrown, grey ear-coverts (some with greenish-yellow wash on rear ear-coverts), narrow but clearly contrasting pale eyering (most noticeable behind and below eye), yellow moustachial and malar area that continues into yellow throat; nape and upperparts pale grey, sometimes spotty yellow wash on lower back and rump; below, yellow of throat separated from yellow of belly by grey fringes on breast feathers, also flanks greyish, crissum off-white; upperwing pattern distinctive, largely greyish, with bright yellow on shoulder continuing as yellow panel on outer greater upperwing-coverts, with primaries and secondaries, including tertials, fringed pale greyish; tail greyish, yellow edges at base of outer rectrices; iris dark brown; bill dark grey, often with light blue-grey on most of lower mandible; legs dull pinkish. Female is dull greyish-brown, with distinctive pale eyering bolder behind and below eye; lesser and median upperwing-coverts with yellow area as on male, but less distinct, and yellow below restricted to belly. Juvenile resembles female, but slightly streaked breast and flanks, warm brown wash on mantle, pale cinnamon edges on greater upperwing-coverts, yellow shoulder and pale eyering already present, primaries tipped white, yellow lower mandible. VOICE. Song relatively fast and harsh, but warbled, lasting 2–4 seconds, "twipa-twipa chup twipa trrrr chuptrrr twipa"; another version is short and quickly delivered paired notes, "chzwi-pa chzwhipa", repeated after an interval longer than song itself. Call a high "tiip".
Habitat. Dry Patagonian steppe, with bunch-grass adjacent to more open flat zones with pebbles and low vegetation, or adjacent to open shrubby zones; road cutting or other dry bank, even if very low, required for nesting. Sea-level to 600 m; higher, to 1200 m, on Argentine Patagonian plateaux.
Food and Feeding. Seeds and small insects. Forages on ground. Most often found in pairs or small flocks of 4–8 individuals, rarely up to 20.
Breeding. Season Nov–Feb. Digs tunnel in earthen bank and builds nest at end of this; gravel pits, road cuts and probably riverbanks often used for tunnel-digging because much of habitat is flat.Clutch 4–6 eggs. No further information available.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon throughout much of its range.
Bibliography. Armani (1985), Canevari *et al.* (1991), Cozzani *et al.* (2008), Dunning (2008), Fjeldså & Krabbe (1990), Johnson & Goodall (1967), Narosky *et al.* (1984), Ridgely & Tudor (1989).

231. **Orange-fronted Yellow-finch**
Sicalis columbiana

French: Sicale à béret **German**: Zwerggilbammer **Spanish**: Chirigüe Frentinaranja
Other common names: Orange-fronted Grass-finch; Venezuelan Yellow-finch (*columbiana*)

Taxonomy. *Sycalis columbiana* Cabanis, 1851, "Porto Cabello"; error = Ciudad Bolívar, River Orinoco, Venezuela.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Three subspecies recognized.
Subspecies and Distribution.
S. c. columbiana Cabanis, 1851 – C Venezuela in delta and basin of R Orinoco, and E Colombia (Meta and Vichada); has bred once in Trinidad.
S. c. goeldii Berlepsch, 1906 – Amazon Basin of Brazil from about R Purus E to lower R Tapajós and S Amapá.
S. c. leopoldinae Hellmayr, 1906 – EC Brazil in S Maranhão, Piauí, W Pernambuco, N & W Bahia, Tocantins and Goiás.



Descriptive notes. 11·5 cm; 11·6–16·1 g. A compact yellow-finch with very short tail and wing, large and rounded head, and a bill large for the bird's size. Male nominate race has yellow head with orange forehead and forecrown, darker lores and short dark eyeline; upperparts olive-yellow, throat and underparts bright yellow, tinge of saffron on breast side and flanks; upperwing entirely greenish-yellow but for dusky centres of tertials; tail dark with wide yellow edging, particularly at base; iris dark; bill horn-brown to blackish above, dull yellowish-grey below; legs yellowish-dusky to dull pink. Differs from similar *S. flaveola* in smaller size, contrasting orange forehead not extending to rear crown, short dark eyeline. Female is olive-brown above, whitish below, with pale yellowish breastband, pale yellowish rear flanks and crissum; head brownish with darker lores, sometimes faint yellowish wash on supercilium, crown darker; mantle and back greyish-brown, contrasting greenish-yellow wings (upperwing-coverts, as well as edges of primaries and secondaries), greenish lower back and rump; tail feathers with greenish edging. Juvenile is similar to female, but slightly streaked on breast, and wings buff-fringed, rather than greenish-washed; immature male a duller, paler version of adult, some nearly lacking orange tone on forehead, and much duller yellow throughout. Race *goeldii* male has breast washed orange; *leopoldinae* smaller than nominate, with much smaller, weaker bill, brighter forecrown patch, and brighter yellowish-green back, female paler than nominate above and below. VOICE. Song a short and chirpy series of unmusical notes. Call a nasal "zhwit"; flight call described as a soft "chu-re-reet". Flocks sound like large group of House Sparrows (*Passer domesticus*).
Habitat. Shrubby zones in riparian sites, usually adjacent to grassy areas; closely tied to water, such as streams, lakes or ponds. Sea-level to 300 m.
Food and Feeding. No details of diet. Forages on ground, also commonly perches in shrubs and small trees; may obtain some food from arboreal substrates. Found in pairs or small groups; outside breeding season in larger flocks, sometimes with *S. flaveola*.
Breeding. Season Jun–Nov in Venezuela; once in Sept in Trinidad. Nest in Venezuela placed in crevice in wall, another in abandoned nesting burrow of kingfisher (Alcedinidae); clutch 4 eggs. Single nest in Trinidad cup-shaped, made from grass stems and roots, placed in hollow at end of broken branch c. 4 m from ground; contained 3 eggs, whitish-green with brown markings, these concentrated at wide end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally fairly common to common. Recorded once in Trinidad, in 1926: several individuals observed, and nesting confirmed. Single old record from NE Peru (Loreto). In some areas this species is trapped for cagebird trade; losses considered not great enough to pose significant risk to population.
Bibliography. Armani (1985), Dunning (2008), ffrench (1991), Restall *et al.* (2006), Ridgely & Tudor (1989).

232. **Saffron Finch**
Sicalis flaveola

French: Sicale bouton-d'or **German**: Safrangilbammer **Spanish**: Chirigüe Azafranado
Other common names: (Saffron) Yellow Finch; Pelzeln's Finch ("*pelzelni* group"); Pereyra's Yellow-finch ("*S. striata*")

Taxonomy. *Fringilla flaveola* Linnaeus, 1766, no locality = Suriname.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Races form two groups, "*flaveola* group" (nominate and *valida*) and "*pelzelni* group" (*pelzelni*, *brasiliensis* and *koenigi*), these differing dramatically in female and immature plumages and, to lesser extent, in male plumage; also, latter group exhibits strong sexual dimorphism, while "*flaveola* group" does not. These groups may warrant treatment as two separate species; further research required. Disjunct trans-Andean *valida* possibly also a distinct species, meriting detailed assessment. Birds of higher areas of S Bolivia currently included in race *pelzelni*, but may belong in *koenigi*. Proposed taxon *S. striata* (described from Buenos Aires, in Argentina) invalid, based on a specimen regarded as a breeding male of race *pelzelni* in immature plumage. Five subspecies recognized.
Subspecies and Distribution.
S. f. flaveola (Linnaeus, 1766) – N & E Colombia (S to Meta), Venezuela S to R Orinoco (also NW Amazonas), coasts of the Guianas, and Trinidad.
S. f. valida Bangs & T. E. Penard, 1921 – coastal slope in Ecuador (Guayaquil) S to NW Peru (Ancash).
S. f. brasiliensis (J. F. Gmelin, 1789) – E Brazil from Maranhão, Minas Gerais and São Paulo E to Atlantic coast.

S. f. pelzelni P. L. Sclater, 1872 – Bolivia E of Andes (S from S Beni), SE Brazil (S from Mato Grosso and Santa Catarina), Paraguay, E Argentina (S to E Mendoza, La Pampa and Buenos Aires) and Uruguay; recently also in Chile (Los Ríos and Los Lagos; possibly introduced).
S. f. koenigi Hoy, 1978 – NW Argentina (Salta and Jujuy).
Introduced (probably nominate race) in Panama, Jamaica, Puerto Rico and Hawaiian Is.

Descriptive notes. 13·5–15 cm; 12–23·4 g. A medium-sized and well-proportioned yellow-finch with rather short wing and tail, and relatively large bill. Male nominate race has head yellow, slightly more orange forehead and forecrown (on some orange wash extends to throat and face); upperparts only slightly greener, mantle with obscure streaking (visible only in very close inspection); below, entirely lemon-yellow and unpatterned; upperwing looks largely greenish-yellow owing to greenish-yellow coverts, and edging of primaries and secondaries, tertials dark with narrower greenish-yellow edges; tail dark with broad yellowish edging; iris dark brown; bill dusky above and on tip, most of lower mandible yellowish; legs dull flesh-coloured to dusky brown. Female is similar to male, but less vibrant in colour and with reduced orange on crown (slight differences in coloration obvious when sexes seen together), and with much less yellow on central abdomen. Juvenile has greyish head with slightly darker eyeline, dark-streaked light brown upperparts, rump olive-yellow, flight-feathers and rectrices edged yellowish-olive, throat and underparts greyish with light streaking, crissum yellow; immature similar, but with broad yellow breastband; adult plumage acquired in second year. Races differ mainly in plumage: *valida* is darker than nominate, more reddish on forecrown, and greenish above extending to nape, bill heavier, legs pinkish; *pelzelni* is smaller-billed, longer-winged, and relatively shorter-tailed than nominate, plumage much less bright, has slight saffron wash on forehead (seldom extensive), yellowish face, rest of head greenish, back very much greener and with distinct fine narrow streaks, yellowish edging of flight-feathers and wing-coverts narrower (dark centres more evident), duller yellow below, some males with ill-defined streaking on underparts, female is entirely unlike nominate, greyish-brown and streaked throughout above, brownish wings with paler edgings on coverts, dull greenish edges on flight-feathers (but tertials edged pale greyish-brown), greenish edges at bases of rectrices, pale malar area contrasting with narrow submoustachial stripe, throat plain whitish-buff, underparts off-white, finely streaked breast and flanks, dull greyish-horn lower mandible; *brasiliensis* male is brighter yellow than previous race, with orange wash on crown, bill longer and more laterally compressed; *koenigi* is similar to last, but bill shorter and not so compressed. Voice. Song lively and pleasant, notes spaced enough to give calm and pleasing whistled nature, "zwhit, cheew, tzuup, cheew, peepa pew, tzuup, chew..."; much variation, but song always pleasing and made up largely of sweet-sounding notes, sometimes with a few harsher notes, and, unlike most congeners, not suggesting a trill or chatter. Typical call an upslurred "whip", also a short "tuup".
Habitat. Wide variety of habitats, usually semi-open with scattered trees or shrubs, including open dry forest, savanna, thorn-scrub, *chaco* woodlands, edges of marshes and waterbodies, gallery-forest edge, roadside scrub, second growth, agricultural areas; also lawns in towns and cities. Usually below 1000 m; to 2000 m in dry intermontane valleys of Bolivia.
Food and Feeding. Seeds, also small arthropods. Forages on ground, often on lawns in urban areas. Found in pairs and in small flocks.
Breeding. Season late May to Nov in Venezuela, Apr–Jan in Trinidad, Oct–Feb in E & S of range ("*pelzelni* group"), possibly later in Bolivia (fledging in May in Cochabamba); typically two broods per season. Males often sings from conspicuous branch, post or powerline. Nest a bulky semi-sphere of dry grasses, lined with softer material, including hair, placed in palm frond or in cavity, e.g. pipe, roof eave or nestbox, in Trinidad almost always in abandoned nest of Yellow Oriole (*Icterus nigrogularis*); in S & E ("*pelzeni* group") usually builds within old stick or mud nest of furnariid, commonly old nest of Rufous Hornero (*Furnarius rufus*), Firewood-gatherer (*Anumbius annumbi*) or thornbird (*Phacellodomus*), sometimes in artificial structure such as city light fixture. Clutch 2–4 eggs, creamy with purplish-brown markings; "*pelzelni* group" commonly 4 eggs, cream-coloured or pale greenish with brown and grey speckling throughout; no information on incubation and nestling periods. Nests often parasitized by Shiny Cowbird (*Molothrus bonariensis*), at least in Argentina. Reports that juveniles of first brood may nest within season in which they hatched likely erroneous.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common to abundant throughout its very large range. Recently found in SC Chile (Los Ríos and Los Lagos), but unclear whether this due to natural colonization or artificial introduction. Introduced successfully to West Indies, first in Jamaica in 1820s, and in Puerto Rico probably c. 1960; now well established in both, and particularly common and widespread in Jamaica; also recorded in Cuba. Introduced quite successfully to Hawaii. First reported in Panama in 1951, presumably following introduction or escape from captivity. Widely kept and popular as a cagebird.

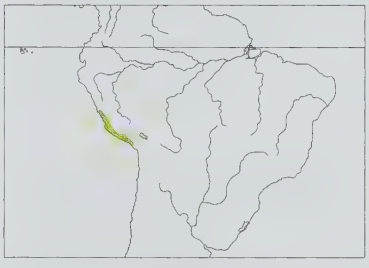
233. Grassland Yellow-finch

Sicalis luteola

French: Sicale des savanes **German**: Kurzschnabel-Gilbammer **Spanish**: Chirigüe Sabanero
Other common names: Striped/Yellow-breasted Yellow-finch, Yellow Grass-finch; Montane Yellow-finch (*bogotensis*); Misto/Southern Yellow-finch (*luteiventris*); Northern Yellow Finch (*chrysops*)

Taxonomy. *Emberiza luteola* Sparrman, 1789, no locality = Suriname.
Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). This species previously considered conspecific with *S. raimondii* owing to similarities in plumage, but the two occur sympatrically in coastal S Peru and behave as good biological species. Has been suggested that races may constitute up to three separate species, nominate, *flavissima* and *chapmani* forming one species, *chrysops*, *mexicana*, *eisenmanni* and *bogotensis* another, and *luteiventris* a third; others suggest that only two main groups are involved, *luteiventris* being a separate species and all other races being conspecific. A detailed study of geographical plumage variation, vocalizations and genetics is needed. Eight subspecies currently recognized.
Subspecies and Distribution.
S. l. mexicana Brodkorb, 1943 – C Mexico (Pacific slope in Puebla and Morelos).
S. l. chrysops P. L. Sclater, 1862 – S Mexico (Caribbean slope in Veracruz and Chiapas), S Guatemala (Sacatepéquez), and Mosquitia region of E Honduras and NE Nicaragua.
S. l. eisenmanni Wetmore, 1953 – NW Costa Rica (Guanacaste) and C Panama (Coclé).
S. l. luteola (Sparrman, 1789) – Colombia (lower elevations of W Andes, and valleys of R Cauca and R Magdalena), Venezuela (Falcón, Monagas and Bolívar), Guyana and adjacent N Brazil (R Branco region).
S. l. bogotensis Chapman, 1924 – Andes of Venezuela and E range in Colombia S through highlands of Ecuador to S Peru (Arequipa).
S. l. flavissima Todd, 1922 – Suriname S to mouth of R Amazon (Brazil).
S. l. chapmani Ridgway, 1899 – lower R Amazon in Brazil (C Pará).
S. l. luteiventris (Meyen, 1834) – breeds in S Brazil (Santa Catarina and Rio Grande do Sul), Uruguay, lowlands of N & C Argentina (Santiago de Estero and Corrientes S to Chubut) and C Chile (S Coquimbo S to Valdivia); winters N to S Peru (Cuzco and Puno), C & E Bolivia (La Paz, Beni and lowland Santa Cruz), C Brazil (Mato Grosso E to Bahia).
Introduced (nominate race) in Lesser Antilles.



Descriptive notes. 9·8–12·5 cm; 14·6–17·9 g. A small, compact yellow-finch with short and rounded bill, moderately long wings and distinctly notched tail. Male nominate race has olive crown with fine dark streaks, largely greyish-olive face with distinct yellowish eyering and yellow supercilium, and also much yellow on side of neck; nape and upperparts olive-brown with heavy dark streaking (in fresh plumage, two whiter lines of streaks on mantle), rump contrastingly olive-yellow; upperwing and tail brownish with pale brownish edgings; throat and malar region bright yellow, underparts yellow, extensively washed olive on side of breast and upper flanks, belly slightly paler yellowish; iris dark; bill greyish or pinkish-grey, darker culmen; legs dull pink to dusky. Female is similar to male, but duller overall, pale brown above with dark streaks from crown to back, dull yellow below, dark malar stripe, yellow facial markings less conspicuous, side of head and side of body strongly washed olive, throat and breast sometimes buff. Juvenile is similar to female, but upperpart feathers edged buffy (can look scaly on freshest-plumaged juvenile, more streaked on older individual), stronger malar stripe, finely streaked breast, belly even duller yellow. Race *flavissima* is larger and longer-winged than nominate, with more curved bill, contrasting unstreaked yellowish rump, female has yellowish throat; *chapmani* is similar to previous, but with even larger bill, much more strongly curved culmen, brighter green upperparts with very narrow streaking, brighter yellow underparts; *bogotensis* is larger than nominate, with head yellower and less contrasting, darker on mantle and scapulars, dull greenish-olive rump, sometimes a pale patch near end of outer pair of rectrices; *chrysops* is brighter than last; *mexicana* and *eisenmanni* are similar to previous; *luteiventris* is rather dull above, rump greener and less contrasting than on nominate, wing edgings stronger and more greyish-yellow (creating paler panel on folded secondaries), sometimes two wingbars, less bright yellow below, olive wash on breast less prominent and less extensive. Voice. Song, from perch and in flight, a canary-like series of trills, each at slightly different frequency from previous one, and with different cadence, duration 3 seconds to more than 10 seconds; flight song longer than perched song, and during intense singing when female present song escalates and towards end trills more like electronic buzz in quality. In Suriname, song much slower and not sounding so much like a series of trills. Call in flight an explosive disyllabic "pit-tchew!"; also gives churring note in Panama.
Habitat. Grasslands and agricultural areas, also grassy edges of marshes and other wetlands. Prefers taller-grass habitats, rather than short grass. In Panama found in savanna with scattered bushes and low trees in sandy soil. In Chile, Argentina and Uruguay often in empty lots within towns or villages, so long as grass and other vegetation taller than c. 1 m. Sea-level to 2500 m in S of range, to 3300 m in Andean portion of distribution. Recorded at sea-level in S Peru (Ica).
Food and Feeding. Seeds, probably also arthropods. Forages mostly on ground. Feeds on seedheads of grasses by flying up and alighting on them, causing stem to bend down, and then extracting seed while braced on ground. Singly, in pairs and in small groups; sometimes in larger flocks.
Breeding. Season Feb–Jun, but may breed in all months, in N of range, and males in breeding condition in Jun in Panama and in May in Colombian highlands; in S (race *luteiventris*) breeds late Aug/Sept–Feb, with up to three broods in a season. In some places may be loosely colonial. Nest a bulky cup of woven grass, placed on ground; in S (*luteiventris*), nest semi-spherical and comprised of dry grass, with softer lining of feathers, hair or soft grass, placed on ground in thick clump of grass or other vegetation. Clutch in N of range 2–3 eggs; in S tends to be of 3–5 eggs, white with pale blue wash and spotted with grey or brown throughout, spots concentrated at wide end.
Movements. Resident in N & W of range. S populations (*luteiventris*) mostly migratory, some birds making post-breeding flight N as far as S Peru, Bolivia and C Brazil; however, N limits of breeding range and S limits of wintering range of this race are unclear; resident in Chile; large flocks of this yellow-finch seen in Santa Cruz (Bolivia) only in austral winter.
Status and Conservation. Not globally threatened. Common to abundant in S cone of South America; fairly common to uncommon and more local in N of range. Race *mexicana* rare and local; *chrysops* very rare in Guatemala. In West Indies, nominate race introduced in Barbados in c. 1900 and subsequently spread to other islands in Lesser Antilles; now uncommon and somewhat local on Antigua, Guadeloupe, Martinique, St Lucia, St Vincent and Grenada, as well as Barbados, and vagrant on Mustique (in Grenadines). Popular as a cagebird.
Bibliography. Armani (1985), Chapman (1924), David *et al.* (2009), Dunning (2008), Fjeldså & Krabbe (1990), Griscom (1932), Guth (1971), Herrera & Vidoz (2009), Jaramillo (2003), Johnson & Goodall (1967), Koepcke (1963), Olrog (1963), de la Peña (1987), Raffaele *et al.* (1998), Restall *et al.* (2006), Ridgely & Tudor (1989), Ridgway (1899, 1901), Rui de Camargo (1995), Salvador & Salvador (1986), Wetmore (1953), Wetmore *et al.* (1984).

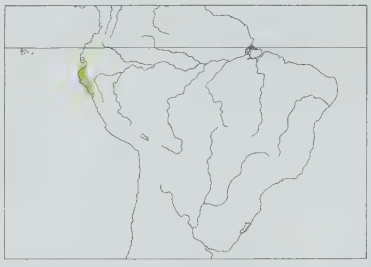
234. Raimondi's Yellow-finch

Sicalis raimondii

French: Sicale de Raimondi **German**: Grauflanken-Gilbammer **Spanish**: Chirigüe de Raimondi

Taxonomy. *Sycalis raimondii* Taczanowski, 1874, vicinity of Lima, Peru. Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). This species previously considered conspecific with *S. luteola* owing to similarities in plumage, but the two occur sympatrically and behave as good biological species. Monotypic.
Distribution. Pacific slope in S Peru from Lima S to extreme N Tacna.

Descriptive notes. 12·5 cm; one female 15·8 g. A small and compact yellow-finch with short rounded bill, moderately long wings and notched tail. Male has largely greyish-olive face, distinct yellowish eyering and yellow supercilium; crown streaked brownish-olive, nape greyish and lightly streaked (or unstreaked); upperparts greyish-olive and indistinctly streaked dark (in fresh plumage, two paler lines of streaks on mantle), rump unstreaked greenish with yellow wash; upperwing brownish, feathers edged pale grey (forming pale panel on folded wing), tail dusky, feathers edged pale greyish-yellow; below, entirely yellow, brightest on throat (which contrasts with greyish-olive face), and washed grey on flanks, with belly paler off-white to yellowish; iris dark; bill greyish-blue, or pinkish-grey with darker culmen; legs dull dusky pink. Female is similar to male, but duller overall, face browner, with pale buff supercilium and off-white eyering, upperparts duller and browner, particularly on rump; dull yellow below, strongest on throat and belly, distinctly grey on breast, also has narrow and indistinct darker malar stripe. Juvenile and immature undescribed. Voice. Song a dry chatter or reedy rattle, "tchitchitchitchitchi". Calls include dry "djer-djer-djer" and rising "kewee?".
Habitat. Arid rocky hillsides, dry grasslands and pastures, at 200–2500 m; sometimes in areas with large cacti and Lomas vegetation. Not found in arable land.
Food and Feeding. No information on diet. Forages on ground. Found in small groups during breeding season; in non-breeding period in flocks of 100–1000 individuals.
Breeding. Nests in stony gorges; apparently colonial. No other information. Unlike closely related *S. luteola*, appears not to have an aerial display.
Movements. Field observations suggest shifts in abundance depending on local patterns of fog and rainfall, but no quantified data. In maritime ranges of Arequipa, present in all months, and most common Dec–Jul, but not known to breed there. May form large flocks (hundreds of individuals) for a period of time, and then disperse.
Status and Conservation. Not globally threatened. Locally common in larger flocks, but these ephemeral. No evidence of major population decreases. Has fairly extensive range.
Bibliography. Armani (1985), Bond (1951a), Dunning (2008), Fjeldså & Krabbe (1990), Hughes (1970), Koepcke (1963, 1970), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).



235. Sulphur-throated Finch

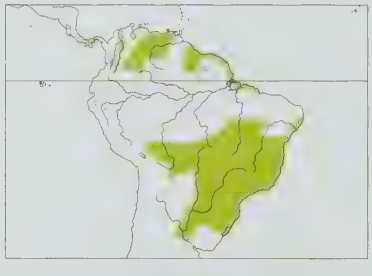
Sicalis taczanowskii

French: Sicale de Taczanowski **Spanish**: Chirigüe de Taczanowski
German: Taczanowskigilbammer
Other common names: Sulphur-breasted Finch, Sulphur-throated Yellow-finch

Taxonomy. *Sycalis taczanowskii* Sharpe, 1888, Tumbes, Peru. Molecular-genetic data suggest that genus is most closely related to the "hooded" group of sierra-finches (*Phrygilus atriceps*, *Phrygilus punensis*, *Phrygilus gayi* and *Phrygilus patagonicus*); also, that it belongs within the tanager family (Thraupidae). Until relatively recently this species was placed in a monotypic genus, *Gnathospiza*, but in many ways it seems to be merely a large-billed member of present genus, and perhaps closest to *S. raimondii* and *S. luteola* on basis of plumage features. Monotypic.
Distribution. SW Ecuador (SW Guayas, El Oro and Loja) and NW Peru (lowlands of Tumbes, Piura, Lambayeque and N La Libertad).
Descriptive notes. 12 cm. A stocky, short-tailed dull-plumaged finch with disproportionately large bill with strongly rounded culmen, and tiny-looking eye. Has dull grey-brown head, slightly streaked on crown and nape, face greyish with yellow wash, yellow strongest on supraloral area and eye-crescents; sometimes a pale patch on side of neck; upperparts dull grey-brown with darker streaking, rump unstreaked greyish; tail feathers brownish, extensively edged yellow, yellow strongest and widest at base; upperwing with narrow greyish-buff wingbars, yellowish edging on primaries; throat and malar region strongly tinged yellow, underparts pale greyish-brown, flanks with narrow dark streaking; iris dark; bill dull

On following pages: 236. Wedge-tailed Grass-finch (*Emberizoides herbicola*); 237. Lesser Grass-finch (*Emberizoides ypiranganus*); 238. Duida Grass-finch (*Emberizoides duidae*); 239. Great Pampa-finch (*Embernagra platensis*); 240. Pale-throated Pampa-finch (*Embernagra longicauda*); 241. Coal-crested Finch (*Charitospiza eucosma*); 242. Black-masked Finch (*Coryphaspiza melanotis*); 243. Pileated Finch (*Coryphospingus pileatus*); 244. Red-crested Finch (*Coryphospingus cucullatus*); 245. Crimson-breasted Finch (*Rhodospingus cruentus*); 246. Yellow Cardinal (*Gubernatrix cristata*).

horn with pinkish tone; legs pale pink. Sexes alike. Immature is similar to adult, but weakly streaked on breast and lacks yellow on face and throat. Voice. Song unrecorded. Calls include thin "tzzzz" and "tur", as well as warbling phrases with scratchy character.
Habitat. Desert scrub and areas of low trees, also extremely dry and barren areas where vegetation nearly absent; sea-level to 300 m.
Food and Feeding. No details of diet; large bill size suggests that it feeds on large seeds. Forages while on ground. Feeds in large flocks, sometimes of hundreds of individuals.
Breeding. No information.
Movements. Largely resident. Appears to stay in general region where it breeds, but somewhat nomadic or erratic within desert habitat when not breeding; forms large flocks during non-breeding season, but not known to be migratory.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Common within its limited range in Peru. Rare and erratic in Ecuador, where absent during years of rain; recent report from SW Esmeraldas, in N Ecuador.
Bibliography. Armani (1985), Montalvo (2009), Restall *et al.* (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).



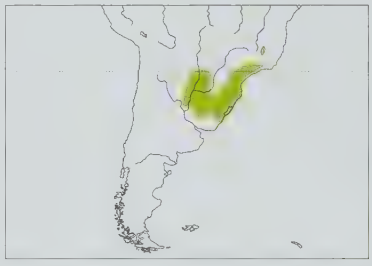
Genus *EMBERIZOIDES* Temminck, 1822

236. **Wedge-tailed Grass-finch**

Emberizoides herbicola

French: Grand Tardivole **German**: Keilschwanzammer **Spanish**: Coludo Colicuña
Other common names: Wedge-tailed Ground-finch, Azara's Grass-finch

Taxonomy. *Sylvia herbicola* Vieillot, 1817, Paraguay.
Molecular data indicate that genus is sister to *Embernagra*, and both appear to belong in tanager family (Thraupidae). Sometimes treated as conspecific with *E. ypiranganus*; until recently considered conspecific with *E. duidae*. Races fall roughly into two groups, "*sphenurus* group" (*sphenurus*, *hypochondriacus*, *lucaris* and *apurensis*) N of R Amazon, and single-species "*herbicola* group" (nominate race) in S; groups differ in plumage and voice, and in playback experiments nominate does not react to songs from *apurensis*, suggesting that more than one species may be involved; geographical limits of some races require confirmation.Race *lucaris* may be similar enough to be subsumed into *hypochondriacus*; further study required. Proposed race *floresae*, described from Panama (Cerro Flores, in E Chiriquí), appears to be based on an immature specimen, and is treated as a synonym of *hypochondriacus*. Five subspecies recognized.
Subspecies and Distribution.
E. h. lucaris Bangs, 1908 – SW Costa Rica (Térraba region).
E. h. hypochondriacus Hellmayr, 1906 – W & C Panama.
E. h. sphenurus (Vieillot, 1818) – locally in Colombia, S Ecuador and N Peru, and in Venezuela (except W lowlands and Cerro Duida), the Guianas, and NE Brazil (S to N Maranhão).
E. h. apurensis Gilliard, 1940 – lowland W Venezuela (Guárico, Portuguesa, Barinas and Apure).
E. h. herbicola (Vieillot, 1817) – E Bolivia (Beni, La Paz, Santa Cruz and Chuquisaca), C, E & S Brazil (Mato Grosso E to Pernambuco, S to Rio Grande do Sul), Paraguay, N Argentina (Formosa and Misiones S to Entre Ríos and N Santa Fe) and N Uruguay (Rivera).



Descriptive notes. 20–20·3 cm; 21–36·6 g. A medium-sized finch with thickset body, but relatively slim appearance owing to very long and pointed tail, and with moderately deep-based bill with slightly curved culmen; tail feathers lanceolate, and inner two pairs very long and sharply pointed, giving tail a forked shape in some views, but quickly become abraded, leaving only pointed shafts. Nominate race has face plain pale brownish, dull paler supraloral streak and pale lores, diffuse whitish eyering; crown finely streaked blackish, nape largely unstreaked; upperparts boldly streaked blackish, blackish streaks roughly the same in width as brown edging; rump unstreaked, uppertail-coverts narrowly streaked; upperwing brownish, feathers widely edged bright olive-green; tail feathers dark-centred, edged greyish-brown; throat greyish-white, underparts creamy white, flanks and vent buff; iris dark brown; bill largely yellow to yellow-orange, blackish culmen; legs brownish-yellow to dull pinkish. Sexes alike. Juvenile is similar to adult, but upperparts suffused with rusty yellow, and face and underparts suffused yellow, streaked on breast. Races differ in size and in plumage, nominate largest, with palest face, and least broad streaking above: *lucaris* is most similar to nominate in plumage, but noticeably more rusty above than it and all other races; *hypochondriacus* is more yellowish-brown on upperparts than previous, and has blackish-grey ear-coverts; *sphenurus* resembles last, but is larger, buffier below, with restricted streaking on breast side and dark shaft streaks on undertail-coverts; *apurensis* is like last, but with greyish face, darker greyish-brown with blacker streaking above, and whiter below, finely streaked on flanks. Voice. Song of nominate race sweet and pleasant, a melodious double whistle, the first upwardly inflected, the second downwardly inflected, "jewléé, jewlóóó"; a longer, more complex dawn song starts and ends with short rough notes and contains sweeter notes in middle, "chk chk teu jeulóó chk chk". Call "tsik" or "chik". Rather different are songs of *sphenurus* and *apurensis*, respectively "ch,ch,ch,r,r,ree-chwee,ye" and "tit-tit-zur-rreeeet"; dawn song in Venezuela shorter, "t'chill'ip". In Panama (*hypochondriacus*) two song types, a buzzy "tsiritsitzeew" or "tzit-zeereea" and a sweet "tit-leeoo" or "tleedee" repeated at intervals. More work needed on geographical variation in song and its possible taxonomic significance.
Habitat. Damp to well-drained grasslands and meadows, usually with isolated shrubs; requires taller older grass (sensitive to overgrazing). Also savanna habitats, particularly in S of range (nominate race). Sea-level to 1500 m.
Food and Feeding. Few details available; diet apparently seeds and arthropods. Forages on ground, or near ground in tall grasses. Sometimes follows army ants (Formicidae). Singly and in pairs.
Breeding. Season Nov–Jan in S (nominate race); fledglings in Nov and Jun in Venezuela (*apurensis*). Dawn song of nominate usually accompanied by jerky flight display. In Argentina cup-shaped nest of dry grasses, placed in dense tuft of grass; clutch 3 eggs, white with blackish marks, these denser around wide end. In Brazil (Serra do Cipó National Park, in Minas Gerais) two nests were lined with floral peduncles of *Leiothrix* cf. *spiralis* (Eriocaulaceae), built at base of *Lagenocarpus tenuifolius* (Cyperaceae); one contained 2 eggs, and the other two nestlings. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common; possibly less common N of R Amazon than S of it. No significant threats known.
Bibliography. Armani (1985), Canevari *et al.* (1991), Di Giacomo & Di Giacomo (2006), Dunning (2008), Eisenmann & Short (1982), Fjeldså & Krabbe (1990), Graham *et al.* (1980), Griscom (1924), Hennessey *et al.* (2003), Klicka *et al.* (2007), Restall *et al.* (2006), Ridgely & Tudor (1989), Tobias *et al.* (1997), de Vasconcelos (2000), Wetmore *et al.* (1984).

237. **Lesser Grass-finch**

Emberizoides ypiranganus

French: Petit Tardivole **German**: Ypirangaammer **Spanish**: Coludo Chico
Other common names: Lesser Ground-finch, Grey-cheeked Grass-finch

Taxonomy. *Emberizoides macrourus ypiranganus* H. von Ihering and R. von Ihering, 1907, Campos de Jordão, Serra de Itatiaya and Ypirangana, São Paulo, Brazil.
Molecular data indicate that genus is sister to *Embernagra*, and both appear to belong in tanager family (Thraupidae). Sometimes treated as conspecific with *E. herbicola*, with which it was formerly confused. Monotypic.
Distribution. Paraguay (largely E of R Paraguay), NE Argentina (E Formosa, E Chaco, NE Santa Fe, Corrientes and E Entre Ríos), SE Brazil (S Minas Gerais, S São Paulo, SW Rio de Janeiro and S Paraná S to Rio Grande do Sul) and N & C Uruguay.

Descriptive notes. 20 cm; 18·5–22 g. A medium-sized finch with thickset body, though relatively slim appearance owing to very long and pointed tail, and with moderately deep-based bill with slightly curved culmen; tail feathers lanceolate, and inner two pairs very long and sharply pointed, giving tail a forked shape in some views, but quickly becomes abraded, leaving only pointed shafts. Has plain greyish face with darker lores and paler supercilum, narrow whitish eyering; greener or browner crown contrasts with grey face and is finely streaked blackish, nape largely unstreaked; upperparts with bold blackish streaks roughly equal in width to dull brown or greenish-brown edgings, rump to uppertail-coverts narrowly streaked; tail feathers dark-centred and edged greyish-brown; upperwing brownish, feathers widely edged bright green; throat white, underparts pale greyish-white, buff flanks, flanks and vent streaked; iris dark brown; bill largely yellow-orange, blackish culmen; legs brownish-yellow to dull pinkish. Sexes alike. Juvenile is similar to adult, upperparts suffused with buffy yellow, face and below suffused yellow, and breast streaked. Voice. Song, often from concealed perch in vegetation, also from prominent perch, rarely in flight, a harsh monotonous chatter, "ch-ch-ch-ch-ch..." or "wet-wet-wet...", usually notes doubled towards end of song, e.g. "ch, ch, ch, ch, ch, ch-ch, ch-ch, ch-h...". Call "tse".
Habitat. Moist grassland to swampy meadows and marsh, including sedge (Cyperaceae) marsh; found also in drier grassland, including grassy patches adjacent to shrubs. Sea-level to 900 m.
Food and Feeding. No information on diet. Forages on ground, usually in grass and difficult to see. Singly and in pairs.
Breeding. Season Nov–Jan. Little known. Rarely performs aerial song display. Two nests described from Brazil (Serra do Cipó National Park, in Minas Gerais), each a relatively deep cup, some dried leaves of *Panicum loreum* at base, lined with floral peduncles of *Leiothrix* cf. *spiralis*, placed 12–14 cm above ground at base of *Lagenocarpus tenuifolius*; in Argentina nests 7–70 cm above ground, e.g. in midst of clump of *Paspalum intermedium* grass, one nest had external diameter 6·5–7 cm, internal diameter 4–4·5 cm, external height 6 cm and internal depth 5 cm. Clutch 2–3 eggs, white with few reddish, brown or black spots at broad end. No other information.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Uncommon to fairly common throughout range.
Bibliography. Armani (1985), Costa *et al.* (2008), Di Giacomo (1998), Dunning (2008), Eisenmann & Short (1982), Klicka *et al.* (2007), Ridgely & Tudor (1989), Tobias *et al.* (1997), Webster & Webster (1999).

238. **Duida Grass-finch**

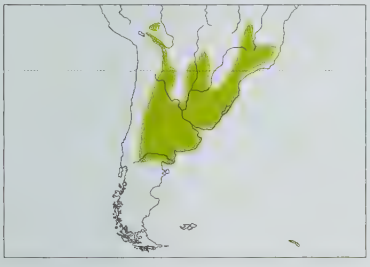
Emberizoides duidae

French: Tardivole du Duida **German**: Duidaammer **Spanish**: Coludo del Duida
Other common names: (Mount) Duida Ground-finch

Taxonomy. *Emberizoides duidae* Chapman, 1929, Cerro Duida, 4400 feet [c. 1340 m], Amazonas, Venezuela.
Molecular data indicate that genus is sister to *Embernagra*, and both appear to belong in tanager family (Thraupidae). Until recently considered conspecific with *E. herbicola*. Monotypic.
Distribution. Cerro Duida (Amazonas), in S Venezuela.

Descriptive notes. 22 cm. A stocky finch with thickset body, looking relatively slim owing to very long and pointed tail, and with moderately deep-based bill with slightly curved culmen; tail feathers lanceolate, and inner two pairs very long and sharply pointed, giving tail a forked shape in some views, but quickly abrades, leaving only pointed shafts. Has rather plain dark brownish face with darker lores, contrasting whitish supraloral stripe and narrow whitish eyering; forehead blackish, crown brown with widely blackish streaking (looking black more than brown); mantle and scapulars olive, boldly streaked blackish, rest of upperparts cinnamon-brown, boldly streaked blackish, streaks similar in width to visible background colour;

tail feathers dark-centred, edged brown; upperwing brownish, widely edged yellow-green; throat whitish-buff, pale brownish breastband, buff flanks and white belly, flanks and vent streaked; iris dark brown; bill largely yellowish, blackish culmen; legs brownish. Sexes alike. Juvenile is streaked on breast, and white of underparts replaced by buffy. VOICE. No information.
Habitat. Savanna habitats in upper tropical and subtropical zone; 1300–2100 m.
Food and Feeding. No information.
Breeding. No information.
Movements. Presumed sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Tepuis EBA. Not known in life, but only from a handful of specimens. Has tiny global range, restricted to a single mountain. Although its habitats are secure at present, and mostly inaccessible to humans, any future changes in land use or in climate could lead to its becoming threatened. Efforts should be made to find this species and to document its biology and ecology and its current population level.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Chapman (1929), Eisenmann & Short (1982), Hilty (2003), Klicka *et al.* (2007), Restall *et al.* (2006), Ridgely & Tudor (1989), Stattersfield & Capper (2000).



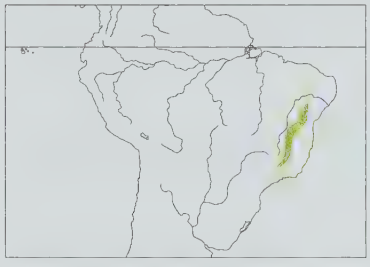
Genus *EMBERNAGRA* Lesson, 1831

239. Great Pampa-finch

Embernagra platensis

French: Embernagre à cinq couleurs **German**: Pampaammer **Spanish**: Coludo Verdón
Other common names: Red-billed Pampa-finch; Olive Pampa-finch (*olivascens*)

Taxonomy. *Emberiza platensis* J. F. Gmelin, 1789, Buenos Aires, Argentina.
Molecular data indicate that genus is sister to *Emberizoides*, and both appear to belong in tanager family (Thraupidae). This species sometimes placed in *Emberizoides*. Western "*olivascens* group" may merit elevation to species rank; in Argentina, nominate race may be sympatric with *gossei* in Córdoba, but no details available. Four subspecies recognized.
Subspecies and Distribution.
E. p. olivascens d'Orbigny, 1839 – SE Bolivia (La Paz, Cochabamba and W Santa Cruz S to E Potosí and W Tarija), W Paraguay, and NW Argentina (Salta and Jujuy E to C Formosa, S through Córdoba).
E. p. catamarcana Nores, 1986 – C Catamarca, in NW Argentina.
E. p. gossei C. Chubb, 1918 – WC Argentina (Mendoza, San Juan and San Luis).
E. p. platensis (J. F. Gmelin, 1789) – lowlands of Beni, in N Bolivia; C & E Paraguay, E Argentina (E Formosa, Chaco and Misiones S to Río Negro), SE Brazil (S from Minas Gerais) and Uruguay.



Descriptive notes. 20·5–23 cm; 45–47 g. A long-tailed and short-winged finch of medium size, with thick yet long bill. Nominate race has grey head, with darker lores and face (creating somewhat masked look), from nape a green suffusion invades the grey, blending into grass-green upperparts, mantle and back varying from finely to distinctly streaked; tail feathers dusky with broad grass-green edging, greenish central feathers; upperwing widely edged grass-green and appearing largely concolorous with back, except for broad blackish centres of tertials; grey of face continues to underparts, with slightly paler central throat, then darkening on breast and flanks, with belly and vent off-white, rearmost underparts often with cinnamon-brown wash; iris dark brown; bill orange, black culmen; legs usually dull pinkish, feet often duller and duskier. Sexes similar. Juvenile is rather different from adult, strongly washed yellow on face and throat, strong face pattern of yellow supercilium contrasting with darker cap and cheek, crisp whitish crescent below eye, entire upperside pale brownish with prominent dark streaking, off-white to yellowish below, crisp streaking on breast and upper flanks, bill dusky. Race *olivascens* is larger than nominate, has thicker bill with more strongly curved culmen, lacks streaking above, has buff-brown wash on flanks and rear underparts, has much more extensive and brighter orange coloration on bill (dark restricted to basal ridge of culmen), legs bright yellow to orange; *gossei* is larger than previous, has paler grey throat and breast, more greyish-green upperparts; *catamarcana* has clearer grey chest and greyer head than preceding two, also more yellowish on upperparts and has whiter belly. VOICE. Song c. 1 second in duration, a musical series of 3–5 notes of generally high frequency, last note often longer, louder and strongly frequency-modulated, "gledit, gledit, gléeeeuuu" or "pzt–tcheew" or "chip–ptleeéé"; when final note rising, reminiscent of part of Brown-headed Cowbird (*Molothrus ater*) song. Song of *olivascens* may be more complex, longer and lower in frequency. Call a buzzy "tziip"; alarm call a buzzy "tzip, tzip, tzip".
Habitat. Grassland with scattered shrubs, also grassland at edge of marshes. In E of range (nominate) prefers moist sites, avoiding dry grasslands. In W & N much more likely to occupy habitats with larger shrub component, away from damp sites, but still with noticeable grass component. Sea-level to 2500 m. In areas of sympatry with *E. longicauda*, present species tends to occur in more humid parts and at lower elevations, sometimes in cultivation.
Food and Feeding. Feeds on mix of seeds and arthropods, latter being more important during breeding period. Forages while on ground. Sometimes follows army ants (Formicidae). In pairs and family groups
Breeding. Egg dates span Oct–Dec, later in NW part of range; fledglings recorded Nov–Mar. Nest a cup of dry vegetation, sticks and twigs, lined with softer and finer material, placed 30 cm to 1·5 m from ground in pampas grass (*Cortaderia selloana*), thick grasses or dense shrub. Clutch 2–4 eggs, white with ochre and blackish markings, these concentrated around wide end. Often parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common. Appears to adapt well to agriculture so long as some tall grass present on outside of farm fields, and often perches on and sings from fence posts.
Bibliography. Armani (1985), Beltzer (1990), Canevari *et al.* (1991), Contreras (1980), Di Giacomo & Di Giacomo (2006), Dunning (2008), Fjeldså & Krabbe (1990), Hayes (2003), Hennessey *et al.* (2003), Klicka *et al.* (2007), Mattos & Sick (1985), Montalti *et al.* (2005), Nores & Yzurieta (1986), de la Peña (1987), Ridgely & Tudor (1989), Storer (1989b), de Vasconcelos (2000).

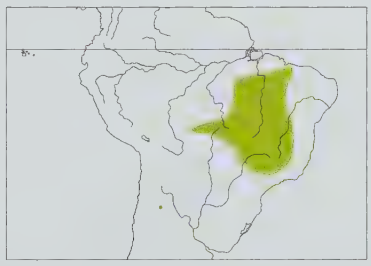
240. Pale-throated Pampa-finch

Embernagra longicauda

French: Embernagre du Brésil **German**: Langschwanzammer **Spanish**: Coludo Gorjipálido
Other common names: Buff-throated Pampa-finch, (Pale-throated) Serra-finch

Taxonomy. *Embernagra longicauda* Strickland, 1844, South America.
Molecular data indicate that genus is sister to *Emberizoides*, and both appear to belong in tanager family (Thraupidae). Monotypic.
Distribution. Highlands of C Bahia, C Minas Gerais and extreme SW Espírito Santo, in E Brazil.

Descriptive notes. 21·5 cm. A slim and very long-tailed and short-winged finch of medium size, with stout and long bill. Has grey head with darker lores and eyeline, contrasting pale supraloral spot, well-defined white crescent above and below eye; upperparts plain greenish-grey; upperwing widely edged grass-green (looks much brighter than back); tail feathers dusky with broad grass-green edging, greenish central feathers; throat white, contrasting greyer breast and slightly browner flanks, with belly and vent off-white, often a warm buff wash on undertail-coverts; iris dark; bill yellow to orange-yellow, black culmen; legs greyish to flesh-orange or even dusky, feet often more olive. Sexes similar. Juvenile is different from adult, strongly washed yellow on face and throat, strong face pattern of yellow supercilium contrasting with darker cap and cheek, prominent whitish crescent above and below eye, brownish above with strong streaking throughout, warm brown wash on wings, tail dull brown, underparts grey with yellowish wash, crisp streaking on breast, bill dusky. VOICE. Song a loud "tsi, tsoweee", repeated at intervals of 4–5 seconds. Call a buzzy "tziiup".
Habitat. *Serra* habitat in highlands of E Brazil, in dry savannas, *campos* grasslands, grassy fields with a few scattered palms (e.g. *Allagoptera*) and ground bromeliads; 900–2100 m. In areas of sympatry with *E. platensis*, present species tends to occur in more arid parts and at higher elevations.
Food and Feeding. Little known. Forages on ground. During breeding season commonly found in family groups, typically of 4 individuals.
Breeding. Little known. Apparently at least Oct–Dec. Nest found in Oct in Minas Gerais, a cup lined with *Leiothrix* cf. *spiralis* peduncles, built 38 cm above ground inside clump of *Panicum loreum*; contained 2 eggs, white with small brown dots and paler blotches at wide end. Fledged young seen foraging in company of their parents. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to locally fairly common. Has fairly small and fragmented range. Confined to E Brazil, where it occurs in Serra do Espinhaco (interior C Bahia and Minas Gerais); recently discovered in some isolated ranges in surrounding region, including Serra da Mombuca (Minas Gerais) and also in Serra do Caparaó, in adjacent Espírito Santo. Possibly more widespread in surrounding ranges than previously thought. Has suffered some habitat loss through agricultural expansion; on other hand, deforestation may create additional habitat suitable for this species. Recorded in at least eight protected areas.
Bibliography. Alves *et al.* (2009), Anon. (2010c), Butchart & Stattersfield (2004), de Freitas & Rodrigues (2008), de Freitas, de Vasconcelos & Rodrigues (2009), Hoffmann *et al.* (2009), Klicka *et al.* (2007), Machado *et al.* (1998), Mattos & Sick (1985), O'Brien (1968), Ridgely & Tudor (1989), Sick (1993), Stattersfield & Capper (2000), de Vasconcelos (2000), de Vasconcelos & de Araujo Silva (2003), de Vasconcelos *et al.* (2003).



Genus *CHARITOSPIZA* Oberholser, 1905

241. Coal-crested Finch

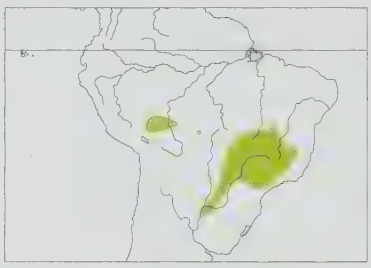
Charitospiza eucosma

French: Charitospize charbonnier **Spanish**: Monterita Crestada
German: Weißwangen-Zwergkardinal

Taxonomy. *Charitospiza eucosma* Oberholser, 1905, Fazenda Valo [= Geral do Valo], near frontier of Minas Gerais, Bahia, Brazil. Originally named *Fringilla ornata*, but that name invalid, as preoccupied. Probably belongs in tanager family (Thraupidae), and thought likely to belong in the group that includes *Diuca*, *Lophospingus*, *Paroaria* cardinals and a few others. Monotypic.
Distribution. EC Brazil from SE Pará, S Maranhão and NC Piauí, S to SE Mato Grosso, NW São Paulo and W Minas Gerais; recently found in extreme NE Bolivia (N Santa Cruz) and N Argentina (Tafí del Valle, in Santiago del Estero).

Descriptive notes. 11·5 cm. Small plump-bodied finch with relatively long triangular bill with straight culmen and gonys, and with distinctive thin crest. Male has top of head, including crest (often held flat), lores, anterior cheek, chin and throat black, contrasting silvery-white patch on ear-coverts and area behind eye, this pale patch gradually darkening to blue-grey nape; upperparts, including upperwing-coverts, pale blue-grey like nape, greater upperwing-coverts often paler than lesser and median coverts (forming silvery-grey wingpanel); flight-feathers black, small white patch towards base of inner primaries (visible both on perched and on flying bird), tertial edges pale blue-grey; tail blackish, white bases of outer rectrices (obvious in flight); black of throat extends down as pointed bib on breast; lower breast, belly and flanks pale buffy cinnamon, often darker and with chestnut tone on breast, undertail-coverts buffy cinnamon; iris dark brown; bill blue-grey, dark culmen; legs pinkish-grey. Female is much duller than male, largely brown above and pale buffy cinnamon below, crest brownish and poorly developed; face has slightly paler area on cheek, but this not prominent (a "ghost" pattern of male), throat usually whitish, and often a

faint darker malar stripe; flight-feathers black, contrasting with brownish coverts, tail blackish with noticeable white at base of outer rectrices; legs dull pinkish. Juvenile apparently undescribed. Voice. Song pleasant and loud, but tempo resembles that of Red-eyed Vireo (*Vireo olivaceus*), whistled phrases lasting c. 1 second and separated by longer intervals of 1·5–2 seconds, phrases sweet and ringing, often repeated notes, e.g. "turichup...cheerycheery...herichup...tweewtweew...tweechew...". Call an inconspicuous thin high-pitched "tip"; flight call a more muffled "tzip", given at frequent intervals; alarm a buzzy, nasal "phaap".
Habitat. *Cerrado* habitat with grass, and scattered shrubs and low trees, also *caatinga* habitats; grassy savanna. Appears to gather in greater concentrations in patches of *cerrado* which have recently been burnt. Sea-level to 1200 m.
Food and Feeding. Presumably seeds and insects. Forages while on ground, often in patches of bare earth; will also forage in low shrubs. Inconspicuous. Generally in pairs and in small flocks.
Breeding. Nest found in late Oct in *cerrado* of Brasília. Nest a shallow cup with external diameter 6·8 cm, height 3·3 cm, located 1·21 m above ground on horizontal fork of young *Aspidosperma tomentosum* (Apocynaceae); contained 2 eggs, blue-green with many brown markings. No other information.
Movements. Appears to perform local movements tied to rainfall patterns, as well as following habitats created by fire succession.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon and local. Has moderately small global population likely to be declining owing to habitat loss caused by conversion of *cerrado* to agriculture, as well as effects of trapping for cagebird trade. One historical record from NE Argentina (Misiones). Often considered a fire specialist, as its numbers at localities increase after fire. Surveys needed in order to document population size, and protection of *cerrado* urgently required.
Bibliography. Anon. (2010c), Armani (1985), Borges & Marini (2008), Butchart & Stattersfield (2004), Cavalcanti & Alves (1997), Herrera & Maillard (2007), Klicka *et al.* (2007), Ridgely & Tudor (1989), Stattersfield & Capper (2000).



Genus *CORYPHASPIZA* G. R. Gray, 1840

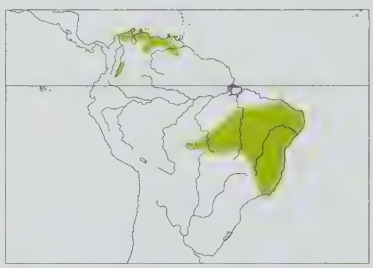
242. **Black-masked Finch**

Coryphaspiza melanotis

French: Coryphaspize à joues noires **Spanish**: Cachilo Enmascarado
German: Schwarzkopfammer
Other common names: Black-eared Finch

Taxonomy. *Emberizoides melanotis* Temminck, 1822, Ipanema, São Paulo, Brazil.
This species most likely belongs in tanager family (Thraupidae); aspects of plumage, tail shape, juvenile plumage and song suggest that it may be related to *Embernagra* and *Emberizoides*. Two subspecies recognized.
Subspecies and Distribution.
C. m. marajoara Sick, 1967 – Marajó I (mouth of R Amazon in Pará), in N Brazil.
C. m. melanotis (Temminck, 1822) – extreme SE Peru (Madre de Dios), E Bolivia (La Paz and Beni), C & EC Brazil (E Mato Grosso and Mato Grosso do Sul E to Minas Gerais and São Paulo), E Paraguay, and NE Argentina (Corrientes).

Descriptive notes. 13·5 cm; 15·6–15·8 g. A relatively thickset finch, with rather long and graduated tail, stout thick-based bill with gently curved culmen. Nominate race somewhat variable, especially on upperparts; has forehead and central crown black, very broad white supercilium widest immediately before eye and tapering somewhat to blunt point on side of nape; lores and area below eye rearwards to behind ear-coverts black (forming complete black mask), contrasting strongly with white throat; nape greyish, mantle and upper back greyish-olive with blackish streaks, lower back and rump greyish; upperwing greenish, marginal coverts yellow, inner greater upperwing-coverts greyish, tertials with greyish edging; some birds show feathers of mantle, scapulars, tertials and outer greater upperwing-coverts chestnut-brown with pale edges and ill-defined dark brown central streak; tail blackish, central rectrices grey, outer feathers with large white tips on inner web (obvious in flight), outer edge of outermost rectrix white; white below, sometimes tinged creamy-buff, spur of black on side of breast, blackish patches or streaking on flanks; yellowish wing-linings; iris dark; upper mandible black, lower mandible bright yellow; legs dull pink. Sexes similar. Juvenile is greyish-brown above and streaked throughout, wings only slightly more greenish than back, wing-coverts with dark centres and brown edgings, crown and face streaked, lacks black mask and white supercilium, instead havaing yellowish wash on lores and superciliary area, yellowish throat and breast, breast obscurely streaked brown, rest of underparts whitish, white tips of outer rectrices much reduced and central rectrices more olive-coloured, bill dull blackish above and horn-coloured below. Race *marajoara* is slightly smaller than nominate, with broader, blacker streaking on back. Voice. Song high-pitched and insect-like, a set of paired notes so closely spaced as to sound like one frequency-modulated note, "tziieeep", repeated at intervals of c. 2 seconds; sometimes slightly different phrase types used consecutively, "tziieep...tsi-tsip...zz-tzzz...". Call a high-pitched "tsiip".
Habitat. Tall-grass habitats with scattered low shrubs; requires relatively open grassland, and is absent if shrub component too high. Found also on edges of seasonally flooded *campo limpo* and *campo sujo* in Minas Gerais (Brazil). In Beni (Bolivia) occupies areas of tussocky grass 50–125 cm tall with scrubby mounds. In Paraguay, observed in *campo sujo* comprising pristine tussocky grasses with small areas of bare ground, scattered bushes and yata'i palms (*Butia*). To 1200 m.
Food and Feeding. No information on diet. Foraging on ground under tall grass; sometimes forages in more open areas at edge of grassland or on bare earth. Usually in pairs; during non-breeding season may form larger flocks within the grassland.
Breeding. No information. Season probably Sept–Dec.
Movements. Resident.
Status and Conservation. VULNERABLE. Uncommon to rare, and very local, and decreasing. Has suffered extensive habitat loss, and likely to be in rapid decline. Main continuing threats are overgrazing, burning of grasslands, and large-scale tree-planting. Throughout most of this species. range, suitable grasslands are being destroyed at rapid rate by intensive cattle-ranching, mechanized agriculture, afforestation, invasive grasses, excessive use of pesticides and annual burning; since 1950, alteration and destruction of *cerrado* has increased and only a small fraction of this habitat now remains. In Bolivia, burning of grassland a significant problem, often caused by uncontrolled fires. This species is protected by law in Paraguay. It occurs in Brasília and Serra da Canastra National Parks (Brazil), Mbaracayú Forest Nature Reserve and Isla Yacyreta Private Reserve (Paraguay) and Beni Biological Station (Bolivia).
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Dunning (2008), de Freitas, Chaves & dos Santos (2009), Graham *et al.* (1980), Lopes *et al.* (2010), Ridgely & Tudor (1989), Stattersfield & Capper (2000).



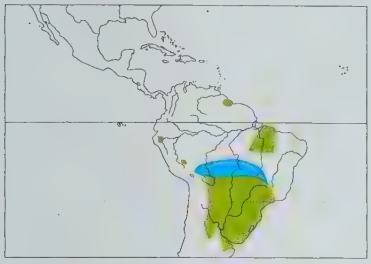
Genus *CORYPHOSPINGUS* Cabanis, 1851

243. **Pileated Finch**

Coryphospingus pileatus

French: Araguira gris **German**: Graukronfink **Spanish**: Soldadito Capirotado
Other common names: Grey Pileated-finch

Taxonomy. *Fringilla pileata* Wied, 1821, Barra da Vareda, Rio Pardo, southern Bahia, Brazil.
Molecular data strongly indicate that genus belongs in tanager family (Thraupidae) and is sister to a group containing *Lanio*, Fulvous-crested Tanager (*Tachyphonus surinamus*), *Trichothraupis* and *Eucometis*. Present species sometimes considered conspecific with *C. cucullatus*; hybrids between the two reported in Brazil. Three subspecies recognized.
Subspecies and Distribution.
C. p. brevicaudus Cory, 1916 – N Colombia (Santa Marta Mts) and N Venezuela from Zulia E, including Margarita I, to Sucre and S to N Bolívar.
C. p. rostratus A. H. Miller, 1947 – upper Magdalena Valley, in Colombia.
C. p. pileatus (Wied, 1821) – C & E Brazil from C Mato Grosso E to S Maranhão and Ceará, S to Goiás, E Minas Gerais and Rio de Janeiro.



Descriptive notes. 13·5 cm; 12–18 g (Venezuela). A compact finch with relatively short tail, short crest, and longish bill with curved culmen. Male nominate race has black crown and crest (tends to be kept flat) with bold red stripe down centre of crown, face entirely grey, noticeable white crescents above and below eye; nape and upperparts entirely greyish, upperwing and tail more blackish-grey; throat white, underparts whitish, dull greyish wash on sides and flanks; iris dark; upper mandible blackish, lower mandible horn to greyish; legs dark grey. Female dull greyish-brown above, and off-white below with buff-grey flanks; lacks black and red on crown, but has whitish eye-crescents as in male. Juvenile like female but slightly more olive, and streaked below. Race *brevicaudus* has shorter tail than nominate, also paler loral area; *rostratus* similar to nominate, but has noticeably longer bill and relatively short tail. Voice. Somewhat repetitive song similar to those of some *Poospiza*, a series of spaced notes, often with repetitions of two, and frequent changes to slightly different phrase types, notes themselves loud and rich whistles with muffled or ringing quality, not sweet whistles, e.g. "phwee chup chup twee chup juup chewe phwee chup chup..."; one song type repeats same note with slightly different accent every few notes, "chwee chwee chwee chw chwee chwee chwee..."; sometimes also a simple repetition of two note types which alternate, "chwee teew chwee teew chwee teew...". Call a sharp "twiip!" or slightly lower-pitched "phfft".
Habitat. Low arid woodlands, usually open woodlands, and dry scrub; also shrubby borders of moister forest, grassy roadsides, second growth, and hedges; sea-level to 1000 m.
Food and Feeding. No details of diet. Forages on ground, usually in dry areas adjacent to shrubbery; may forage also within shrubs and low vegetation. Forms small flocks, primarily in non-breeding season.
Breeding. Breeds during wet season, Apr/May–Oct/Nov, in N Venezuela, precise timing dependent on onset of rainy season (also, years of high rainfall produce higher numbers of juveniles than dry years); moult begins in earnest in Aug, suggesting that breeding activity largely completed by then. Full-grown juveniles in Jan, suggesting breeding Oct–Dec, in upper Magdalena Valley (Colombia). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Common or fairly common throughout most of range. Has rather large range, and what appears to be a stable population.
Bibliography. Armani (1985), Burns & Racicot (2009), Cornet (1999), Hilty & Brown (1986), Klicka *et al.* (2007), McCarthy (2006), Miller (1947), Restall *et al.* (2006), Ridgely & Tudor (1989), Tarroux & McNeil (2003).

244. **Red-crested Finch**

Coryphospingus cucullatus

French: Araguira rougeâtre **German**: Haubenkronfink **Spanish**: Soldadito Crestirrojo
Other common names: Red-pileated Finch

Taxonomy. *Fringilla cucullata* Statius Müller, 1776, Cayenne, French Guiana.
Molecular data strongly indicate that genus belongs in tanager family (Thraupidae) and is sister to a group containing *Lanio*, Fulvous-crested Tanager (*Tachyphonus surinamus*), *Trichothraupis* and *Eucometis*. Present species sometimes considered conspecific with *C. pileatus*; hybrids between the two reported in Brazil. Race *fargoi* slightly more greyish in S of range than in N, and S population described as a separate race, *araguira*, but differences considered trivial. Three subspecies recognized.
Subspecies and Distribution.
C. c. cucullatus (Statius Müller, 1776) – Guyana, Suriname and NE Brazil (E Pará).
C. c. fargoi Brodkorb, 1938 – extreme S Ecuador (S Zamora-Chinchipe), NW & SE Peru (upper Marañón Valley and Urubamba Valley), Bolivia (La Paz, S Beni, Cochabamba, Santa Cruz, Chuquisaca and Tarija), W Paraguay and N Argentina (S to La Rioja, San Luis, La Pampa and N Buenos Aires).
C. c. rubescens (Swainson, 1825) – C & S Brazil (S from S Mato Grosso, S Goiás, W Minas Gerais and São Paulo), E Paraguay, NE Argentina E of R Paraná, and Uruguay.
Also present (race unclear) during austral winter, from N Bolivia E to EC Brazil (NW Minas Gerais).

Descriptive notes. 13·5 cm; 11–18 g. A compact finch with relatively short tail, short crest tending to be held flattened, and longish bill with curved culmen. Male nominate race has black crown and crest with bold red stripe down crown centre, dull greyish face with noticeable white crescents above and below eye, often browner on ear-coverts; nape and upperparts entirely warm brown, upperwing and tail more blackish than upperparts; throat red, becoming bolder red on breast, and duller reddish throughout rest of underparts, except for greyish-washed reddish flanks; iris dark brown; upper mandible blackish, lower mandible paler horn to pale bluish-grey; legs brownish. Female lacks black and red on crown, is dull brown above, paler below, with reddish wash strongest on breast and rump; has whitish eye-crescents like those of male. Juvenile is like female, but slightly more olive in colour and streaked below. Race *rubescens* is like nominate, but has smaller and more slender bill, and underparts richer red; *fargoi* is duller red on underparts, also has duller brown (less reddish) upperparts than nominate. VOICE. Somewhat repetitive song similar to that of some *Poospiza*, a series of two alternating loud and rich whistles, cleanly delivered, though with ringing quality, not sweet whistles, e.g. "chwee teew chwee teew chwee teew..."; some versions slightly faster, but seemingly nearly always two alternating notes, and generally a simpler song than that of *C. pileatus*. Call a sharp "twiip!" or slightly lower-pitched "phfft".
Habitat. Dry shrubby areas, sometimes adjacent to riparian sites, taller tropical forest, grassland and even edges of villages or towns, and parks and gardens; also savannas, agricultural areas, second growth, and *chaco* woodland and *espinal* (thorny woodland) thickets. Typically in younger second growth and disturbed sites. Sea-level mainly to 1400 m; to 3100 m in dry valleys of Bolivia.
Food and Feeding. No information on diet. Forages on ground, both in open dirt areas and beneath shrubs and other vegetation; may also forage in low shrubs. Usually observed singly or in pairs; may form small flocks in non-breeding season.
Breeding. Season mainly Nov–Feb. Nest cup-shaped, made of small twigs, fine vine stems and incorporating dry grasses, lichens, leaf veins and spider webs, lining includes leaves and fine dry fibres, placed 1·5–1·8 m above ground in well-hidden area with dense foliage, such as in vine thicket, along trunk of tree where many branchlets attached, or in trifurcation of branch in shrub. Clutch 2–3 eggs, white and unmarked. No other information.
Movements. Mostly resident. During austral winter, some S birds apparently move N, extending somewhat N of breeding range in Bolivia and C Brazil.
Status and Conservation. Not globally threatened. Common to abundant in heart of range; uncommon in Ecuador, rare in Suriname. Historical records from French Guiana, but no recent reports from that country. Has large range, and population shows no signs of marked declines. This species may benefit greatly from areas of forest giving way to second growth, and perhaps even from agricultural expansion in native grasslands.
Bibliography. Alessio *et al.* (2005), Armani (1985), Bosche (1989), Burns & Racicot (2009), Canevari *et al.* (1991), Dorn (1980a), Hennessey *et al.* (2003), Klicka *et al.* (2007), McCarthy (2006), de la Peña (1980, 1987), Restall *et al.* (2006), Ridgely & Tudor (1989), Stahl (1999), Storer (1989b), Wetmore (1926).

Genus *RHODOSPINGUS* Sharpe, 1888

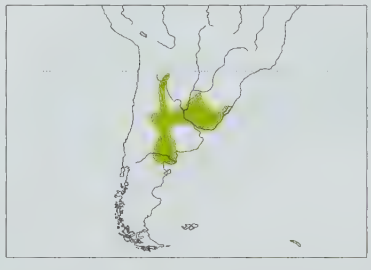
245. Crimson-breasted Finch

Rhodospingus cruentus

French: Rhodospingue ponceau **German**: Purpurkronfink **Spanish**: Soldadito Carmesí
Other common names: Crimson Finch, Crimson Finch-tanager

Taxonomy. *Tiaris cruentus* Lesson, 1844, Guayaquil, Ecuador.
Molecular data strongly indicate that genus belongs in tanager family (Thraupidae), and is sister to a group containing many members of *Tachyphonus*. Monotypic.
Distribution. W Ecuador (W Pichincha and Esmeraldas) S along coastal slope and plain to NW Peru (S to Piura and S Lambayeque).

Descriptive notes. 11 cm; average 11·6 g. A small finch with short-tailed appearance, and long and slender bill with rather straight culmen and gonys. Male has blackish head, including nape and side of face down to just above malar area, bright red coronal patch in middle of crown (can be raised like a short crest); upperparts, including upperwing and tail, blackish; throat red, this colour increasing in intensity to crimson-red on breast, and then less intense red on lower breast and belly; vent and undertail-coverts often whitish with pink wash, sometimes with dark centres on undertail-coverts; in fresh plumage has olive feather tips on back, nape and sometimes face; iris dark brown; upper mandible blackish, often blue grey cutting edges, lower mandible blue-grey; legs dark greyish. Female is very different from male, extremely dull in colour and unmarked, suggesting a female *Sporophila* but with longer and straighter bill; essentially pale brownish above, including head, upperparts, wings and tail, and buffy or pale yellowish on supercilium, face and underparts, with brownish-washed flanks. Immature is like female, young male often with orange wash on breast. VOICE. Song a buzzy "tsee-tzztzz" or "chwzzzzz" repeated at intervals of 1·5–2 seconds; can be reminiscent in quality of song of *Volatinia jacarina*. Call a sharp "tchip" or a descending "tseer".
Habitat. Understorey of dry forest and desert scrub, also forest borders. Dry scrub and low woodland adjacent to tall-grass areas; also agricultural areas with grass patches and shrubby thickets. Sea-level to 750 m.
Food and Feeding. Seeds; probably also small arthropods, at least during breeding period. Forages both on ground and while clinging to grass stems to extract seeds; more arboreal during breeding season, and more terrestrial during non-breeding season. Singly and in pairs; outside breeding season forages in flocks, often with *Sporophila* seedeaters.
Breeding. Recorded Jan–Apr, during rainy season. Nest typically placed in bush or shrub, towards outer end of branch, often in forks and in midst of bunch of leaves, average 140 cm (49–400) above ground level; nest built by both sexes, an untidy mass of dead grass and other plant stems, lined with finer plant matter, diameter c. 5 cm, depth c. 4·5 cm. Clutch 2–4 eggs (mean 3·21); incubation by female, 10–12 days; nestling period 7–9 days. Hatching success 67–86%, fledging success 55–73%.
Movements. Some evidence for local movements; presence and/or numbers in a given area change depending on rainfall, and time of year. Flocks with seedeaters and other finches in dry season, moving between good foraging areas.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Fairly common to locally common through much of its range. Although this species has only a moderately sized range, its global population is seemingly large, with no evidence of major declines. Forest clearance may be creating additional habitat for it.
Bibliography. Armani (1985), Burns & Racicot (2009), Marchant (1958, 1960), Muller (1967), Ortiz-von Halle (1990), Paynter (1971), Restall *et al.* (2006), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schild (1998), Schulenberg *et al.* (2007).



Genus *GUBERNATRIX* Lesson, 1837

246. Yellow Cardinal

Gubernatrix cristata

French: Commandeur huppé **German**: Grünkardinal **Spanish**: Gobernador Crestado

Taxonomy. *Coccothraustes cristata* Vieillot, 1817, Corrientes, Argentina.
Genus has sometimes been placed with the cardinals (Cardinalidae), but morphological data suggest that this is unwarranted; considered probably part of the tanager group (Thraupidae), but precise taxonomic position and closest relatives remain to be determined; molecular studies required. This species has hybridized with *Diuca diuca* in the wild, perhaps suggesting that it belongs in the tanager clade with *Diuca*, *Paroaria* and others. Monotypic.
Distribution. N & C Argentina (Salta, S Formosa and Corrientes S to E La Pampa and N Río Negro), extreme SE Brazil (S & W Rio Grande do Sul) and Uruguay.

Descriptive notes. 20 cm; 46–50·8 g. A well-proportioned but hefty-bodied finch with pointed crest, and often relatively small-looking bill curved on culmen, giving it a somewhat rounded appearance. Male has black crest beginning on central crown, a bold and wide yellow supercilium contrasting with black lores mask and eyestripe, and noticeable yellow crescent below eye; face otherwise greenish-yellow, with bright yellow submoustachial and malar area bordering black throat; upperparts greenish with narrow darker central streaks, tail feathers blackish with bold yellowish edging, outer rectrices mostly yellow; upperwing blackish, median upperwing-coverts tipped yellow (creating broad yellowish upper wingbar), greater coverts with yellowish edges and tips (creating yellowish wingpanel), flight-feathers heavily edged greenish (giving them an overall greenish look), and tertials edged bright yellow; black of throat ends squarely on upper breast; rest of underparts yellow, with greenish wash on breast and flanks, undertail-coverts bright yellow and usually unmarked; iris dark brown; bill black, grey base of lower mandible; legs black. Female is similar in pattern to male, but differs in coloration: supercilium whitish, turning yellowish behind eye, cheek greyish, lower eye-crescent white, moustachial and malar area white; has throat black (like male), but underparts dominated by olive flanks and breast, with yellow restricted to lower breast, belly, vent and undertail-coverts; upperparts duller, more olive-green, but neatly streaked, and wing edgings olive-green except for white fringes of tertials. Juvenile apparently undescribed. VOICE. Male song, often from near top of larger tree, loud, comprised of three or four syllables repeated in patterns, "wir-wit-chu wir-wit-chu twiit wit-chu tiit wit-chu tiit"; resembles that of Golden-billed Saltator (*Saltator aurantiirostris*) in strength and quality of notes, but longer and more varied. Call a low "tsip".
Habitat. Needs old growth-patches of algarrobo (*Prosopis*) forest, or other larger tree species in *espinal* forest (thorny woodlands). Absent from areas that are too degraded or young, and absent from strictly *pampas* grassland habitats. Sea-level to 700 m.
Food and Feeding. Seeds; possibly also small arthropods. Forages for seeds on ground. The fact that it is often found in *Prosopis* woodland suggests that it may take either insects attracted to this tree or the seeds; fieldwork needed to assess how closely this species is tied to *Prosopis*. Forages in pairs and in family groups.
Breeding. Season Oct–Jan. Nest a large cup-shaped structure made from small twigs and dry grass, lined with moss and fibres, placed 2·5–3 m above ground on branch of small tree or shrub. Clutch 2–3 eggs, pale blue-green with blackish spots, blotches and scrawls throughout entire surface. No other information.
Movements. Resident.
Status and Conservation. ENDANGERED. CITES II. Rare and local. Estimated global population 1500–3000 individuals in 2007. Has declined rapidly, mainly because of trapping for the cagebird market combined with extensive habitat loss. In Uruguay, where previously a common species throughout, now estimated that only 300 individuals remain, concentrated in NW (R Uruguay basin); in Argentina, where formerly widespread and common, populations in NW (e.g. in Salta) appear to have disappeared entirely; in SE Brazil, where always far fewer records, the species may well be extinct. Remaining populations now small and fragmented. Current stronghold, with healthiest populations, probably in SC Argentina. Some of habitat loss suffered by this species is due to wood extraction for furniture-making, as well as charcoal; afforestation programmes have involved the planting of exotic eucalypts (*Eucalyptus*), and such plantations are not accepted as a habitat by this species. In Argentina, occurs in Sierra de las Quijadas and Lihué Calel National Parks and Chancaní Provincial Reserve; recorded also in El Palmar National Park, but possibly now extinct there. Captive-breeding programmes are being established In Uruguay and S Brazil, largely with birds seized from poachers.

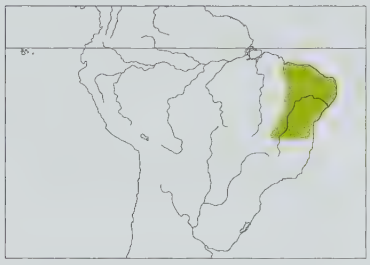
Genus *PAROARIA* Bonaparte, 1832

247. Red-crested Cardinal

Paroaria coronata

French: Paroare huppé **German**: Graukardinal **Spanish**: Cardenilla Crestada
Other common names: Brazilian Cardinal

Taxonomy. *Loxia coronata* J. F. Miller, 1776, no locality = Rio Grande do Sul, Brazil.
Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. dominicana*. Monotypic.
Distribution. E Bolivia (Santa Cruz, locally also S Beni), S & SE Brazil (SW Mato Grosso and S Rio Grande do Sul), W & C Paraguay, N Argentina (S to N Mendoza, C La Pampa and C Buenos Aires) and Uruguay. Introduced to Hawaiian Is.



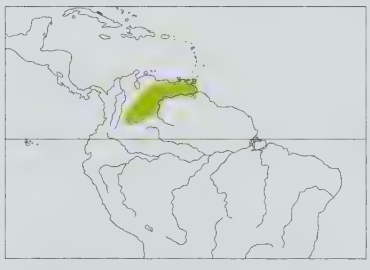
Descriptive notes. 19 cm; 29·5–44 g. A medium-sized passerine with striking red or reddish head and long erectile crest (can be raised to look shaggy, or flattened to look more pointed); bill rather thick and relatively short. Almost entire head red, including crest, ear-coverts, malar region and throat, the red extending down centrally onto mid-breast, creating red "bib"; area of white extends from breast side up to side of neck and side of nape, completely outlining lower border of red head; nape otherwise pale lead-grey, speckled with white on side, grey colour continuing onto upperparts from mantle to rump; upperwing and tail darker, more blackish-grey, feathers edged with similar grey colour to that of upperparts; below, snowy white from bottom of red bib to undertail-coverts, some grey on rear flanks; iris dark brown; bill horn-coloured to blue-grey, dark culmen and tip; legs blackish. Sexes alike. Juvenile is similar to adult, but head and crest dull orange with brownish wash, crown feathers often dark-centred, grey of upperparts washed pale brown, bill darker, with contrasting pinkish gape area. Voice. Song sweet, melodious and slowly delivered, often a repetitive series of alternating notes before other notes added in, generally sounds slow and lazy, "tchew tweet chuu tweet chuu chwiit tuup tweet chuu tweet chuu..." or "weerit, churit, weer, churit"; another song type, given at low volume, very hurried and rather complex, a speedy nasal warble mixed in with sharply frequency-modulated notes. Calls include nasal "phwiit" and "chwup".
Habitat. Varied semi-open habitats, from forest edge to scrub-forest, *chaco* woodlands, *espinal* habitats (thorny woodlands), shrubby zones, agricultural areas, parks, towns and cities, as well as thickets adjacent to marshes and swamps, lakes or rivers. In open country of the Pampas region, often a conspicuous inhabitant of introduced ornamental trees in parkland around *estancia* (farm) headquarters, or other buildings. Sea-level to 500 m.
Food and Feeding. Takes variety of foods, from seeds and berries to insects, also young shoots, and fruit fallen on ground. Forages usually on ground, also in low trees and shrubs. In pairs and small groups; in larger flocks in non-breeding period.
Breeding. Season Sept–Mar. Nest cup-shaped, made from fibres and fine stems, lined with rootlets and hair, placed 1·9–5 m from ground in branches of shrub or tree. Clutch 2–4 eggs, greenish with evenly spread brown markings, or sometimes markings more ochre or even blackish. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common to abundant; often the most common and conspicuous species in the local avifauna. Has large range and is under no immediate threat. Introduced in Hawaii, where present on the major islands; has thrived in Hawaiian lowlands and appears not to have had any negative effects on native landbirds. Commonly trapped for cagebird trade, but this apparently has not adversely influenced its populations. Widely held in captivity, and escapees frequent in and near various centres of population away from natural range, such as Santiago (Chile) and Lima (Peru); some of these may eventually establish free-living populations.
Bibliography. Armani (1985), Bancroft (1982), Canevari *et al.* (1991), Dávalos & Porzecanski (2009), Dinger (2010), Klicka *et al.* (2007), de la Peña (1987), Ridgely & Tudor (1989), Schmid (1975), Storer (1989b), Wetmore (1926), Yuen (1975).

248. Red-cowled Cardinal

Paroaria dominicana

French: Paroare dominicain **German**: Dominikanerkardinal **Spanish**: Cardenilla Dominica
Other common names: Brazilian/Dominican/Pope Cardinal

Taxonomy. *Loxia dominicana* Linnaeus, 1758, Brazil.
Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. coronata*. Monotypic.
Distribution. NE Brazil from S Maranhão, Piauí and Ceará S to E Goiás and N Minas Gerais.
Descriptive notes. 18 cm; 33·2 g. A medium-sized sturdy, thickset passerine with flat crown, rounded peak on rear crown, and somewhat pot-bellied look; bill rather thick and relatively short. Has head including ear-coverts, malar region and throat red, the red extending down centrally onto mid-breast, creating red "bib"; patch of white extends from breast side up to side of neck and side of nape, surrounding lower border of red; nape otherwise blackish, speckled with white at side; mantle and back black with greyish streaking, scapulars contrastingly grey, lower back, rump and uppertail-coverts grey, tail dark grey; upperwing black (again contrasting with grey scapulars), primaries, secondaries and tertials crisply edged white; below, snowy white from bottom edge of bib to undertail-coverts, some grey wash on rear flanks; iris orange-brown; upper mandible blackish; lower mandible horn-coloured; legs greyish. Sexes alike. Juvenile is similar to adult, but head dull orange with brownish wash. Voice. Song sweet, melodious and somewhat repetitive, interspersed with distinctive set of paired notes, "weeet-chup" (first note ascending, second short and descending), e.g. "teew chweet weet-chup chweet teew weet-chup...", generally similar to song of *P. cristata* but more quickly delivered, not lazy-sounding; another song type a very hurried and rather complex warble. Call an inflected "chWUP!".



Habitat. Light *caatinga* woodland and similarly open dry scrubby areas of dry forest; adapts well, can be found also in villages, parks and edge of agricultural areas. Sea-level to 1200 m.
Food and Feeding. Vegetable and insect items. Forages on ground; in pairs and in family groups.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Previously considered Near-threatened, but appears to be more numerous than was realized. Fairly common to common. Extended its range during 1970s, colonizing S Bahia and parts of Minas Gerais. Has fairly large range, and exhibits no significant negative trends in population.
Bibliography. Armani (1985), Dávalos & Porzecanski (2009), Klicka *et al.* (2007), Oren (1982), Restall (1974), Ridgely & Tudor (1989), Sick (1993), da Silva & Oren (1990).

249. Masked Cardinal

Paroaria nigrogenis

French: Paroare masqué **German**: Maskenkardinal **Spanish**: Cardenilla Enmascarada
Other common names: Black-eared Cardinal

Taxonomy. *Nemosia nigro-genis* Lafresnaye, 1846, mouth of the Orinoco, Venezuela.
Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. baeri*, *P. gularis* and *P. capitata* (all four have sometimes been placed in a separate genus, *Coccopsis*). Previously considered conspecific with *P. gularis*, but appears not to be genetically close enough to it to warrant such treatment. Monotypic.
Distribution. E Colombia (Arauca S to N Meta) and N Venezuela in *llanos* along R Orinoco basin (Cojedes S to Barinas and W Apure, E to Delta Amacuro and N Bolívar); also Trinidad.

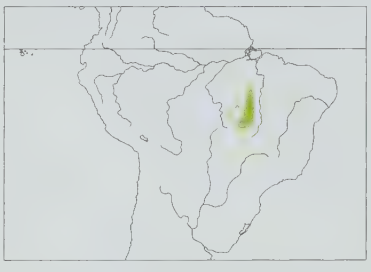
Descriptive notes. 16·5 cm; 23·6 g. A medium-sized passerine, relatively slim and with flat crown, short, rounded occipital crest; bill longer than it is deep, and with culmen gently curved. Has forehead and crown red, lores and ear-coverts black, malar region and throat red, red of throat continuing to upper breast as a red "bib"; area of white extending from breast side up to side of neck and side of nape, completely surrounding lower border of red; nape and upperparts, including upperwing and tail, entirely blackish; below, snowy white from bottom of red bib to undertail-coverts, white flanks; iris intense orange; upper mandible blackish, lower mandible horn-coloured; legs blackish. Sexes alike. Juvenile is similar to adult, but head dull orange with brownish wash. Voice. Song described as series of whistled phrases, "ptchiu wheet pt pt chiu chiieuw wheet chiu chiieer wheet pt pt chiu". Call a sharp "tchep" or soft "chuep".
Habitat. Various open and moist habitats, including wet savanna, and edges of gallery forest near water; also in mangroves in Trinidad. Sea-level to 300 m.
Food and Feeding. Diet appears to be a mix of seeds, vegetable matter, fruit and insects; will also take handouts and bread crumbs. Forages usually on ground, sometimes in areas with much human presence, e.g. parks, car parks, boat mooring areas and the like; also in shrubs. Generally in pairs; in flocks at abundant food sources.
Breeding. Season Jun–Nov in Venezuela (Guárico) and breeds in Sept in Trinidad. Nest a shallow cup made from fine stems and bark, lined with softer material, decorated externally with spider webs, placed in fork of branch c. 3 m above water's surface in swamp. Clutch 2 eggs, pale cream with olive-brown markings, these most heavily concentrated around wide end; no information on incubation and nestling periods. Known to be parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Appears to be sedentary.
Status and Conservation. Not globally threatened. Fairly common to common, particularly in *llanos* of Venezuela; common in larger swamps in Trinidad. Has large range, moderate abundance within this, and no evidence of marked population declines. Popular as a cagebird. Individuals found in unusual places, such as in city centres and the like, are probably escapees from captivity.
Bibliography. Armani (1985), Dávalos & Porzecanski (2009), ffrench (1991), Hilty (2003), Klicka *et al.* (2007), Restall *et al.* (2006).

250. Crimson-fronted Cardinal

Paroaria baeri

French: Paroare de Baer **German**: Blutstirnkardinal **Spanish**: Cardenilla Frentirroja
Other common names: Xingu Cardinal (*xinguensis*)

Taxonomy. *Paroaria baeri* Hellmayr, 1907, River Araguaya, Goiás, Brazil.
Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two



On following pages: 251. Red-capped Cardinal (*Paroaria gularis*); 252. Yellow-billed Cardinal (*Paroaria capitata*); 253. Blue-black Grassquit (*Volatinia jacarina*); 254. Buffy-fronted Seedeater (*Sporophila frontalis*); 255. Temminck's Seedeater (*Sporophila falcirostris*).

genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. nigrogenis*, *P. gularis* and *P. capitata* (all four have sometimes been placed in a separate genus, *Coccopsis*). Individual with plumage intermediate between this species and *P. gularis* photographed in Barreira do Campo, in Pará, suggesting rare instance of naturally occurring hybridization; this putative hybrid resembles *P. nigrogenis*. Has been proposed that race *xinguensis* merits elevation to full species rank, but available evidence thus far inconclusive; further research needed. Two subspecies recognized.

Subspecies and Distribution.

P. b. xinguensis Sick, 1950 – upper R Xingu (S Pará and N Mato Grosso), in EC Brazil.

P. b. baeri Hellmayr, 1907 – NE Mato Grosso, W Tocantins and W Goiás, in EC Brazil.

Descriptive notes. 16·5 cm. A medium-sized passerine, relatively slim and with rounded crown; bill longer than it is deep, and gentle curve of culmen and gonys. Nominate race has largely black head, contrasting crimson-red forehead and forecrown, with throat and submoustachial region also crimson-red, surrounded by black down onto breast; neck and nape entirely blackish; upperparts, including upperwing and tail, blackish; below, snowy white from lower edge of bib to undertail-coverts, flanks also white; iris reddish-orange; upper mandible blackish, lower mandible whitish-horn with small dark tip; legs blackish. Sexes alike. Juvenile is similar to adult, but red areas of head dull orange with brownish wash. Race *xinguensis* is similar to nominate, but throat black, isolating red submoustachial area. Voice. Song rather vigorous, includes a series of descending, harsh whistles, "chewk-chik-chewk-chewk". Calls include harsh "tshrik" and nasal "phht".

Habitat. Riverside forests; to 400 m.

Food and Feeding. Little known. Forages low in shrubs, near the water; may perch on floating vegetation while foraging.

Breeding. No information.

Movements. Sedentary.

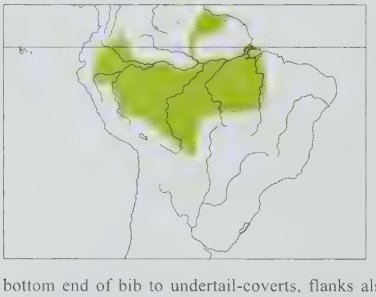
Status and Conservation. Not globally threatened. Fairly common. Has small range, within which seems to be moderately common, and no evidence of marked population declines.

Bibliography. Armani (1985), Dávalos & Porzecanski (2009), Dornas (2008), Klicka *et al.* (2007), Ridgely & Tudor (1989), Sick (1993).

251. **Red-capped Cardinal**

Paroaria gularis

French: Paroare rougecap **German**: Schwarzkehlkardinal **Spanish**: Cardenilla Capirroja
Other common names: Bolivian Cardinal (*cervicalis*)



Taxonomy. *Tanagra gularis* Linnaeus, 1766, Cayenne, French Guiana.

Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. nigrogenis*, *P. baeri* and *P. capitata* (all four have sometimes been placed in a separate genus, *Coccopsis*); appears to be closest to last of those. Previously considered conspecific with *P. nigrogenis*, but appears not to be genetically close enough to it to warrant such treatment. Has been proposed that race *cervicalis* be afforded full species rank, but more work needed to determine what degree of reproductive isolation, if any, exists; further, specimens from S part of range of nominate have reduced black around eyes, suggesting that variation possibly clinal. Two subspecies recognized.

Subspecies and Distribution.

P. g. gularis (Linnaeus, 1766) – E Colombia (S Meta S to Amazonas), E Ecuador and E Peru, S Venezuela (W Amazonas and S Bolívar), the Guianas, and Amazonian lowlands of NC Brazil (including R Negro and mouth of R Amazon).

P. g. cervicalis P. L. Sclater, 1862 – NE Bolivia (Pando, E La Paz, Beni, E Cochabamba and Santa Cruz) and adjacent Brazil (W Mato Grosso).

Descriptive notes. 16·5 cm; 20·8–32 g. A medium-sized passerine, relatively slim and with flat crown and rounded peak on rear crown, in essence a short "mane" (often not visible); bill longer than it is deep, and with gentle curve on culmen and gonys. Nominate race has most of head red, black lores and postocular area, chin and moustachial and malar region also red, throat black, black continuing to upper breast; band of white extending from breast side up to side of neck and side of nape, outlining red rear of head; lower nape and entire upperparts, including upperwings and tail, blackish; below, snowy white from bottom end of bib to undertail-coverts, flanks also white; iris reddish-orange; upper mandible blackish, lower mandible yellowish with small dark tip; legs blackish. Sexes alike. Juvenile is similar to adult, but head dull orange with brownish wash. Race *cervicalis* is similar to nominate, but lacks black around eye. Voice. Song a hesitating, repetitive series of warbles, "cheeber wee? cheeber wee? cheeber", described also as a sweet whistled "suwee chu". Calls include wheezy "rhee?" and "chew", as well as a chatter while in flight.

Habitat. Shrubbery and dense edge areas around lakes, ponds, *cochas* (artificial lagoons), and slow-moving rivers, including black-water rivers; also *várzea* (seasonally flooded) grasslands. Sea-level to 400 m.

Food and Feeding. Vegetable items ranging from seeds to berries, also arthropods. Forages mostly on ground; sometimes while perched on floating vegetation on ponds and lakes. Found in pairs and family groups.

Breeding. Nest constructed from dry grasses and twigs, with softer lining, placed in fork of branch in isolated bush or small tree overhanging water. Clutch commonly 2 eggs, dirty white spotted evenly with sepia and dark brown. In Amazonian watersheds, nests may be lost if water levels rise significantly. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Fairly common to common, and often conspicuous. Said to be very common in interior of Guyana, but rare in Suriname; possibly only a vagrant in French Guiana. Has large range and large population size; appears not to be suffering any major decline.

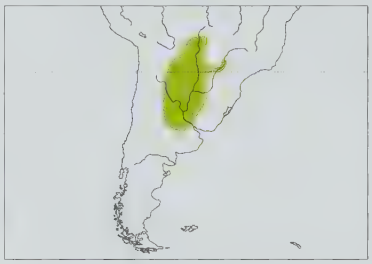
Bibliography. Armani (1985), Buzzetti & Silva (2005), Dávalos & Porzecanski (2009), Eason (1992), Eason & Stamps (1993, 2001), Ingels *et al.* (2003), Klicka *et al.* (2007), Restall *et al.* (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Sick (1993).

252. **Yellow-billed Cardinal**

Paroaria capitata

French: Paroare à bec jaune **German**: Mantelkardinal **Spanish**: Cardenilla Piquigualda

Taxonomy. *Tachyphonus capitatus* d'Orbigny and Lafresnaye, 1837, Corrientes, Argentina.



Recent molecular-genetic research indicates that genus belongs in the tanager family (Thraupidae), forming a clade with, among others, *Cissopis* and *Schistochlamys*; curiously, members of latter two genera are similar in some plumage features and in bill shape to some members of present genus. This species may form a superspecies with *P. nigrogenis*, *P. baeri* and *P. gularis* (all four have sometimes been placed in a separate genus, *Coccopsis*); appears to be closest to last of those. Race *fuscipes* weakly differentiated; species perhaps better treated as monotypic. Two subspecies tentatively recognized.

Subspecies and Distribution.

P. c. capitata (d'Orbigny & Lafresnaye, 1837) – S Brazil (SW Mato Grosso) and adjacent Bolivia (E Santa Cruz) S through Paraguay to N Argentina (E Salta, Formosa and Corrientes S to W Cordoba and N Buenos Aires) and extreme NW Uruguay.

P. c. fuscipes J. Bond & Meyer de Schauensee, 1939 – E Tarija, SE Bolivia.

Introduced (nominate race) in Hawaiian Is.

Descriptive notes. 16·5 cm; 17–24·5 g. A medium-sized, rather slim passerine with rounded crown and somewhat rounded tail; bill longer than it is deep, and with gently curved culmen and relatively fine and pointed tip. Nominate race has entire head, including moustachial and malar region and chin, red, throat black, black narrowing to a point on upper breast; band of white extending from breast side up to side of neck and side of nape, completely outlining red at rear of head; lower nape and entire upperparts, including upperwing and tail, blackish; below, snowy white from end of black bib to undertail-coverts, sometimes a small blackish wedge on rear flanks; iris reddish; bill bright orange-yellow; legs pinkish-orange. Sexes alike. Juvenile is similar to adult, but head dull orange with brownish wash. Race *fusciceps* barely differs from nominate, supposedly has slightly longer bill and more brownish leg colour, but these characters variable. Voice. Song a melodious repetition of 2–3 notes in set pattern, e.g. "tweew wiit-teew, tweew wiit-teew, tweew wiit-teew..."; some songs more quickly delivered, with more twangy-sounding notes. Call a nasal "pheew?".

Habitat. Marshes with shrubs or woody vegetation, flooded grasslands adjacent to shrubs or woody vegetation, and shores of lakes, ponds and rivers; found also at edge of towns, villages, and borders of moist pastures or wet meadows. Sea-level to 500 m.

Food and Feeding. Food includes vegetable matter such as seeds, young shoots and berries, also insects; highly adaptable, and in areas near humans may feed on refuse and even scraps left by people. Forages largely on ground, but also in vegetation. In pairs and family groups or in small flocks; larger flocks in non-breeding season.

Breeding. Season Sept–Mar. Nest cup-shaped, made from fibres and lined with short rootlets and hair, placed 1·4–3·6 m from ground in branches of shrub or tree. Clutch 3–4 eggs, greenish-ochre or creamy with darker ochre or greyish markings spread throughout. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Generally common. Has a substantial range, and no evidence of population declines. Introduced in Hawaii c. 1930, and present on the larger islands. Commonly kept as a cagebird and trapped for this purpose; effect of trapping appears to be minimal.

Bibliography. Almeida Accordi & Barcellos-Silveira (2005), Armani (1985), Butler (1903), Canevari *et al.* (1991), Collins (1976), Dávalos & Porzecanski (2009), Klicka *et al.* (2007), de la Peña (1987), Rattigan (1921), Ridgely & Tudor (1989), Storer (1989b), de Vasconcelos, Werneck & de la Peña (2006), Wetmore (1926).

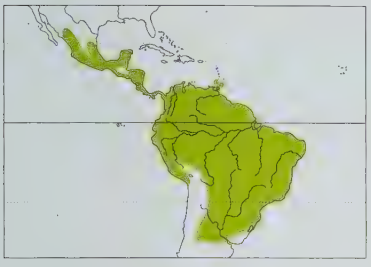
Genus *VOLATINIA* Reichenbach, 1850

253. **Blue-black Grassquit**

Volatinia jacarina

French: Jacarini noir **German**: Jacariniammer **Spanish**: Semillero Volatinero
Other common names: Blue-black Seedeater

Taxonomy. *Tanagra jacarina* Linnaeus, 1766, north-eastern Brazil.



Genus sometimes subsumed in *Geospiza*, but the two appear entirely unrelated. Recent molecular-genetic data indicate that present genus belongs in the tanager family (Thraupidae) and is basal to a clade that includes *Lanio*, *Tachyphonus* and *Ramphocelus*, among others. Proposed race *atronitens* (described from Campeche, in SE Mexico) is synonymized with *splendens*. Three subspecies generally recognized.

Subspecies and Distribution.

V. j. splendens (Vieillot, 1817) – Mexico (S from S Sonora, Sinaloa, Durango, S Tamaulipas and E San Luis Potosí) and Belize S through most of Central America to Colombia, Venezuela, the Guianas and the Amazon Basin; also Trinidad, Tobago and Grenada.

V. j. peruviensis (Peale, 1848) – W Ecuador, W Peru and NW Chile.

V. j. jacarina (Linnaeus, 1766) – S & E Brazil (S from Mato Grosso and Maranhão) S to SE Peru, E Bolivia, Paraguay and N Argentina (S to Mendoza, Córdoba and N Buenos Aires).

Descriptive notes. 8·7–10·9 cm; 8–12 g. Tiny passerine, having longish conical bill with slightly and evenly curved culmen. Male nominate race has head, neck, upperparts and underparts black with dark blue iridescence (in fresh plumage, often narrow brown tips of feather); flight-feathers and tail matt black (lacking iridescence), upperwing-coverts and tertials iridescent like body; patch of white on axillaries and underwing-coverts and at bases of remiges (normally visible only during display), rest of underwing black; iris brown; upper mandible blackish, lower mandible mostly pale grey to horn-coloured; legs grey to greyish-flesh or plumbeous-horn. Female is warm brown, darker above than below, crown, mantle and back very indistinctly streaked, nape and hindneck unstreaked, rump and uppertail-coverts plain warm brown, lacking contrast with back; wings and tail brown, median and greater upperwing-coverts edged brown or buff-brown, paler tips forming two indistinct wingbars, tertials also edged buffy; outer tail feathers tipped buff when fresh; warm buff below (sometimes a cinnamon wash on breast), breast with loose streaks forming distinct streaked breastband that continues to flanks, contrasting with unstreaked throat and belly. Juvenile resembles female, but with darker wings and tail, and coarser and more extensive streaking on underparts; through first winter young male gains blackish feathers in patchy manner throughout body and head, creating patchy calico pattern of streaky brown and black, which is distinctive. Race *splendens* has reduced or little white on axillaries; *peruviensis* is similar to previous, but has more white on axillaries, flight-feathers brownish (instead of blackish), also retains brown immature male plumage for longer time than other races. Voice. Song an emphatic metallic "eee-slick", or "bzeé-eep", or buzzy "b-zeer", often given during flight display just before alighting.
Habitat. Shrubby weedy fields and open thickets, field edges, grassy fields and roadsides, in lowlands; less common in foothills. Sea-level to 2600 m, perhaps even higher in El Salvador.
Food and Feeding. Diet mostly seeds, especially of grasses (in genera *Paspalum* and *Panicum*); also a few insects and berries, and *Cecropia* protein corpuscles. Forages on ground; also picks seeds from grass-heads. In pairs during breeding; at other times in flocks, sometimes large ones, and often associated with other seed-eaters.
Breeding. Season Apr–Oct in whole range, also Nov in NC Venezuela; late May or early Jun to late Aug in El Salvador; sometimes two or three broods raised in a year. Monogamous; extra-pair copulations common. Solitary, but nests often close together and territories small. During display, male "jumps" from perch, flapping wings six times or more, exposing white in underwing, and vocalizes just before landing; may jump several times in a minute. Nest built by both sexes, a small, thin-walled cup of fibres and grasses, lined with finer rootlets and spider webs, placed within 1·2 m of ground in grass of low bush. Clutch 3 eggs, sometimes 2, bluish-white with brownish or purplish spots, these concentrated at larger end; no information on incubation period; chicks fed by both parents, nestling period c. 9 days.
Movements. Apparently sedentary; may move to lower areas from high elevations.
Status and Conservation. Not globally threatened. Generally common to abundant. Often very common, breeding in high densities, at optimum sites. Does well at edges of fields in agricultural areas.
Bibliography. Aguilar *et al.* (2008), Alderton (1963), Almeida & Macedo (2001), Barnard (1956), Carvalho, C.B.V. & Macedo (2002), Carvalho, C.B.V. *et al.* (2006, 2007), de Carvalho, C.T. Genus *SPOROPHILA* Cabanis, 1844

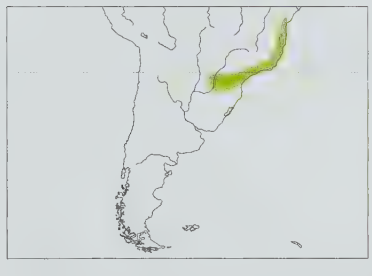
254. Buffy-fronted Seedeater

Sporophila frontalis

French: Sporophile à front blanc **German**: Riesenpfäffchen **Spanish**: Semillero Frentiblanco
Other common names: Buffy-throated Seedeater

Taxonomy. *Callirhynchus frontalis* J. Verreaux, 1869, Cayenne; error = Rio de Janeiro, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Monotypic.
Distribution. SE Brazil (from also S Bahia, Espírito Santo and SE Minas Gerais S to N Rio Grande do Sul), E Paraguay (Alto Paraná) and NE Argentina (Misiones).



Descriptive notes. 12·5 cm; 19·8–21 g. Large seedeater, the largest of genus, with short, deep and strongly rounded bill. Male has head greyish, contrasting creamy and flaring eyebrow behind eye, sometimes a large creamy supraloral patch (supraloral patches do not meet on forehead); upperparts, including upperwing and tail, olive; median and greater upperwing-coverts tipped buffish (forming well-defined bold wingbars), outer primaries with buffish bases (buff "handkerchief" on folded wing); throat and submoustachial area white, contrasting distinctly with darker grey malar stripe and side of face; olive breastband, olive continuing to flanks, otherwise underparts whitish, becoming buffy on undertail-coverts; iris dark; bill orange to dull horn-coloured, often duskier on culmen; legs dull flesh-coloured to blackish. Female lacks grey head and creamy forehead and supercilium of male, is olive throughout, with contrasting buffy-olive wingbars; more evenly pale olive below, lacking white throat of male. Immature male is similar to female, but with whiter throat, indistinct pale postocular supercilium, wingbars brighter buff; some males said never to acquire "normal" adult plumage, these dull-coloured males referred to as having "taquara" plumage. Voice. Song explosive and far-carrying, unmusical and grating, "jeje jet" or "cheh-cheh-chew!"; one less repetitive version starts with a short burst and ends with a thin high-pitched note, "tchp-chiita-tziiip". Female, too, apparently sings (recorded in captivity). Call a sharp "tchew!", repeated at intervals.
Habitat. Lower growth of humid forest, as well as forest edge and shrubby and overgrown clearings adjacent to forest; requires presence of bamboo (*Guadua* and *Chusquea*). At 100–1500 m.
Food and Feeding. Feeds on various grass seeds, especially of bamboo; when seeding bamboo not available, may take larger insects (as suggested by this seedeater's well-developed rictal bristles). Particularly adapted to feeding on bamboo, often of larger-seeded *Guadua*; larger bill of this species suggests overall preference for this genus over *Chusquea*, but will take seeds of latter. In Brazil, commonly feeds on *Merostachy* bamboo, and in Intervales State Park was very abundant while *Merostachys neesii* seeding. Arboreal; forages above ground or while perched on vegetation. In Brazil, may gather in groups of several hundred in Serra do Órgãos when bamboo in mast; in Intervales State Park has been observed to forage with *Haplospiza unicolor* in mixed-species flocks, searching for bamboo seeds towards end of a masting event.
Breeding. Breeding thus far recorded only during bamboo masting events, specifically those involving *Guadua* species. No other information.
Movements. Nomadic in search of seeding bamboo, but remains in general area of distribution throughout year.
Status and Conservation. VULNERABLE. Uncommon to rare, and everywhere irregular. Global population estimated to be in range 2500–9999 individuals, and likely to be declining. Very patchily distributed. In Brazil, most records from Rio de Janeiro, and relatively few in rest of species' range; several recent records in Bahia, including many observed in 2006 in bamboo thicket near Una Biological Reserve; rare in rest of Brazilian range, and no confirmed records from Rio Grande do Sul since 19th century. Only one record from Paraguay, at turn of 19th–20th century; in Argentina, single records from Iguazú in 1978 and Obraje Esmeralda in 1993. Formerly common locally in Brazil, and flocks of sometimes thousands of individuals (perhaps representing high percentage of global population) reported at several localities between 1880s and early 1980s. Since end of 19th century has undergone rapid decline as a result of deforestation, this further exacerbated by the species' clear dependence on bamboo; in addition, trapping for the cagebird trade has had a significant impact on its numbers. Protected under Brazilian law, and occurs regularly in Tijuca, Serra dos Órgãos and Itatiaia National Parks, Serra do Mar, Desengano and Ilha do Cardoso State Parks, and Ubatuba Experimental Station; in Argentina, has occurred in Esmeralda Provincial Park. Main threat is the continuing and rapid clearance of Atlantic Forest, which has resulted in intervals between major bamboo flowerings and this species' breeding attempts becoming longer; its nomadic habits would suggest that existing reserves do not afford adequate protection. Also, trapping for the pet trade is a serious problem; at times, lots of 100–200 individuals of this seedeater have been on sale in Rio de Janeiro.
Bibliography. Anon. (2010c), Areta *et al.* (2009), Armani (1985), Butchart & Stattersfield (2004), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Partridge (1964), Ridgely & Tudor (1989), Sick (1993), Stattersfield & Capper (2000), de Vasconcelos (2002).

255. Temminck's Seedeater

Sporophila falcirostris

French: Sporophile de Temminck **German**: Falzschnabelpfäffchen **Spanish**: Semillero Picudo

Taxonomy. *Pyrrhula falcirostris* Temminck, 1820, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Monotypic.
Distribution. Extreme E Paraguay and NE Argentina (Misiones) and SE Brazil (from S Bahia S on coastal slope to São Paulo and Paraná.

Descriptive notes. 11 cm. Typical seedeater with distinctive bill shape, having narrow and angular upper mandible bending over lower mandible that is at least twice as wide as upper one, with marked bend along cutting edge. Male is almost entirely grey, with white bases of primaries (forming patch on folded wing), and paler belly becoming nearly whitish on vent; iris dark; bill yellow, some males (possibly non-breeding) have duller yellow with dark upper mandible; legs dull brownish to dark grey. Female is dull and nondescript olive-brown above, paler below, lacking any distinctive features; some have marked two-tone appearance on underparts, with belly and undertail-coverts rusty in coloration; bill is horn-coloured above, with yellower mandible. Immature male is like female, some retaining brown plumage, becoming territorial and acquiring bright yellow bill like that of adult male; in captivity, young males keep female-like plumage for many years before becoming grey, and possible that males remain in this plumage until a bamboo masting episode, at which time increased hormonal flow brings on breeding plumage (further study required). Voice. Song can be melodious, but ends with dominating high buzzy trill with electrical tone of a cicada (Cicadidae) stridulation, "ztztztztzt-zt-tzi" or "tsi, si, si, si...tsirrrrrr"; may begin with trill and end with staccato high-pitched notes, "tststststststst ti ti"; some songs slower and more sibilant. Calls include high-pitched descending "tziiip", softer "tslit" and "eet", and disyllabic "ee-eet".
Habitat. Secondary woodland and edge of forests where an abundance of bamboo in understorey; bamboo specialist (*Guadua* and *Chusquea*), but will also accept overgrown edge habitats with giant sedge (*Hypolytrum*). Sea-level to 1200 m.
Food and Feeding. Diet mostly bamboo seeds, sometimes seeds of giant sedge; occasionally insects. Prefers bamboo species in genus *Guadua*, but will take *Chusquea* seeds; appears not to feed on *Merostachys* or *Chusquea tenella*. In NE Argentina up to three species of bamboo used, but seeding occurs en masse and is ephemeral. Will forage also on giant sedge (*Hypolytrum*), possibly as a back-up food supply when bamboo not widely available. Relatively arboreal, perching on vegetation while feeding, rather than foraging on ground; particularly adapted to feeding on seeding bamboo, and usually perches on bamboo while foraging. Also sallies for insects at times. Usually in mobile flocks.
Breeding. Nest found in mid-Aug in Argentina (Iguazú), and birds singing and on territory in Jul in E Paraguay. One nest, built by female, was a cup-shaped structure made from moss, placed 5 m up

in ñandipá tree (*Sorocea ilicifolia*) not too distant from a waterfall; other nests found had external diameter c. 4 cm, built in tree or in sapling. No other information.
Movements. Nomadic, moves around to find seeding bamboo and then concentrates in areas where it is occurring; can then disappear for years from those sites while no bamboo seeding there.
Status and Conservation. VULNERABLE. Rare, sometimes uncommon. Generally rarer than sympatric *S. frontalis*, conversely, during masting events in S of range, in Argentina, may be frequent while that species still extremely rare. Appears to have small and rapidly declining global population. In Brazil, recent records concentrated in Rio de Janeiro and São Paulo, with fewer in Bahia (recent records from three sites), Espírito Santo (1940, 2003–2004 and undated), Minas Gerais (a 1936 specimen) and Paraná (2001–2004, and a 1930 specimen). Recent records in Argentina from Iguazú and from R Paraná in S Misiones; Paraguayan records from Canindeyú (Salto do Guaira in 1977, and Mbaracayú in 1995) and Caaguazú (Caazapá in 1995). Numbers of this seedeater are declining as a result of deforestation, combined with trapping for the cagebird trade; habitat loss exacerbated by its very specific habitat requirements. Continuing clearance of Atlantic Forest has led to even longer periods between nesting attempts, as bamboo flowering and seeding events even more widely scattered; this species' nomadic habits suggest that existing reserves probably inadequate for its protection. Relatively scarce in trade, but this almost certainly is because of its rarity, rather than lack of demand. Legally protected in Brazil. Has occurred in Una and Tinguá Biological Reserves, in Desengano, Serra do Mar, Ilha do Cardoso, Jacupiranga, Intervales, Ilhabela, Pico do Marumbi and Serra da Graciosa State Parks, in Itatiaia National Park, in Juréia-Itatins and Guaraguaçu Ecological Stations and in Ubatuba Experimental Station (all in Brazil); in Paraguay it occurs in Mbaracayú Forest Nature Reserve and Caaguazú National Park, and in Argentina has been found in Iguazú National Park.

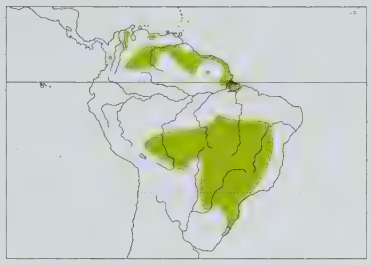
256. Slate-colored Seedeater

Sporophila schistacea

French: Sporophile ardoisé **German**: Schieferpfäffchen **Spanish**: Semillero Pizarroso

Taxonomy. *Spermophila schistacea* Lawrence, 1862, Lion Hill, Canal Zone, Panama.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Present species thought to be highly variable, and has recently been suggested that it be treated as polymorphic, rather than polytypic; further research desirable. Birds from Belize to Nicaragua sometimes separated as race *subconcolor*, but this form is probably best considered a variant of nominate. Three subspecies currently recognized.
Subspecies and Distribution.
S. s. schistacea (Lawrence, 1862) – Belize and N & E Honduras through NE Nicaragua, Costa Rica and Panama to N Colombia and W slope of E Andes.
S. s. incerta Riley, 1914 – Pacific slope of Andes from W Colombia (Caldas) S to N Ecuador (S to Pichincha, also in Napo).
S. s. longipennis C. Chubb, 1921 – W, N & E Venezuela (E slope of Andes S from Mérida, Monagas E to Delta Amacuro, and Bolívar), Colombia (E slope of E Andes S to Meta), the Guianas, Brazil (Roraima, Amapá, N Pará and S Amazonas), N & E Peru (Loreto and Huánuco S to Madre de Dios) and NW Bolivia (Beni and Cochabamba).



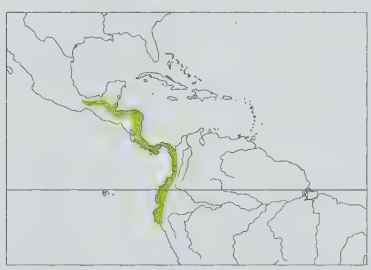
Descriptive notes. 10·6–11·1 cm; 12–13·7 g (Brazil and Peru). Small passerine with large bill. Male nominate race has slate-grey head, upperparts, breast and flanks, white eyering, and white malar stripe which expands on side of neck; bases of inner primaries white, lesser and median upperwing-coverts tipped white; belly and undertail-coverts white; iris dark; bill yellow-orange; legs dark grey. Female is olive-brown, paler below, with creamy buff on central belly; bill brownish. Juvenile resembles female. Race *incerta* is larger than nominate, with thicker bill, white malar patch almost entirely lacking; *longipennis* is like nominate, but slightly paler and more evenly coloured, male with very little or no white malar, female more olivaceous, with little white at base of primaries. Voice. Song variable, often begins with sharp notes and buzzes and ends with high-pitched lisping trill; other versions include sweet lower-pitched whistles interspersed within high-pitched trills; some more melodious with introductory series of more complex whistles, but ending on high-pitched trill. Call a high-pitched note.
Habitat. Edge of humid evergreen forest, second growth and plantations, especially where bamboo present. Recorded up to 1000 m, occasionally 2000 m.
Food and Feeding. Apparently feeds primarily on grass seeds, especially bamboo (e.g. *Chusquea simpliciflora*). Recently observed also to be using rice as a food source. Forages on ground and on inflorescences. Generally seen singly or in pairs; sometimes in small groups.
Breeding. Not well known. Nests in Feb and Jun–Sept (mostly Jul and Aug) in Panama, and Jun in Venezuela (middle R Orinoco region). Nest a thin-walled cup of rootlets and hair, placed 2–4 m above ground in small tree or spiny palm, in Panama 4–5 m up in thorny vine or bamboo. Clutch 3 eggs, greyish-white, dotted and blotched darker; incubation by female, female does most of brood-feeding; no information on duration of incubation and nestling periods.
Movements. Seemingly eruptive and nomadic. A specialist on seeding bamboo, an ephemeral resource; populations shift, being sometimes common at a locality, then disappearing completely. Sporadic in occurrence; appears in small groups to breed where bamboo is seeding.
Status and Conservation. Not globally threatened. Status not well known. Rare to uncommon, but eruptive; can be locally common in some years, and absent in others. Also purportedly recorded in S Mexico, where two specimens said to have been collected in Oaxaca, but origins of these appear questionable.
Bibliography. Armani (1985), Binford (1989), Dunning (1993b), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Meyer de Schauensee (1952a), Neudorf & Blanchfield (1994), Ouellet (1992), Restall (2009), Ridgely & Tudor (1989), Ridgway (1901), Stiles & Skutch (1989), Stutchbury *et al.* (1996), Wetmore *et al.* (1984).

257. Plumbeous Seedeater

Sporophila plumbea

French: Sporophile gris-de-plomb **German**: Graupfäffchen **Spanish**: Semillero Plomizo

Taxonomy. *Fringilla plumbea* Wied, 1830, Campo Geral of inner Brazil = boundary between Bahia and Minas Gerais, eastern Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Three subspecies recognized.
Subspecies and Distribution.
S. p. colombiana (Sharpe, 1888) – S Chocó, lower Magdalena Valley and Santa Marta Mts, in N Colombia.
S. p. whiteleyana (Sharpe, 1888) – NW, N & C Venezuela (Sierra de Perija; Carabobo and Aragua; Bolívar and W Amazonas), *llanos* of E Colombia, the Guianas, and N Brazil (Roraima, and Amapá E to mouth of R Amazon).
S. p. plumbea (Wied, 1830) – extreme SE Peru (Pampas del Heath), N Bolivia (Pando, Beni, Santa Cruz and La Paz), Brazil S of Amazon (Mato Grosso E to Piauí and C Bahia, S to Paraná and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).
Descriptive notes. 10·5–11 cm; 8·8–12 g. Tiny passerine with thick bill approximately as long as it is deep, with distinctly rounded culmen. Male nominate race is lead-grey above, pale lower half of eyering, indistinct streaking on crown and upperparts (except rump); tail feathers blackish, very narrow greyish-olive fringes and warmer buffy tips; upperwing blackish, upperwing-coverts and tertials edged olive-grey (more olive-brown on tertials), primaries with well-demarcated white bases (on folded wing forming small square-shaped white panel not extending to outer two primaries); chin and base of malar tract whitish, surrounding lower mandible (white surround can be quite noticeable in the field); feathers around base of lower mandible whitish, fading to pale grey throat and breast (paler than upperparts), becoming paler lead-grey on belly to undertail-coverts and almost whitish on vent; underwing grey, whitish linings; iris dark; bill and legs black. Female is typical of genus, dull and nondescript, lacking any distinctive features, brownish above and paler buffy brown below, becoming whitish on vent; dark bill with paler horn-coloured lower mandible or base of it. Juvenile is like female, but entire bill horn-coloured; immature male duller grey than adult, with olive tone, and more restricted white around bill base. Race *whiteleyana* is similar to nominate, but male has more contrasting white lower eye-crescent, and more obvious white around base of bill; *colombiana* male is paler grey, with more extensive white on face, entirely white throat. Voice. Sweet song like that of a canary (*Serinus*) or siskin (*Carduelis*), two whistles that sweep up in frequency ("sweet sweet"), followed by more complex and extended set of varied notes and trills, or "juii–juii, jewluh-jehluh, dejewlp-dejewlp"; reported as sometimes including vocalizations of other species, e.g. Great Kiskadee (*Pitangus sulphuratus*) and tody-tyrants (*Todirostrum*). Females in captivity known to sing. Call a loud "jep".



Habitat. Wet savanna and moist tropical grasslands; requires tall grass, and usually found near water or moist habitats; also edge of low forests near grassland, open *cerrado* habitats, edge of riparian habitat, and buriti palm (*Mauritia flexuosa*) groves. Sea-level to 600 m; to 1400 m in Venezuela and 1500 m in Colombia.
Food and Feeding. Forages largely on grass seedheads; seeds of *Andropogon* grasses recorded in diet. Forages on ground or while perched on grass stems. Found singly and in small flocks; will form flocks with other seedeaters.
Breeding. Birds in breeding condition during Nov and Dec in S Brazil. No other information.
Movements. Little known; possibly migratory in S part of range, as it disappears from those sites in austral winter.
Status and Conservation. Not globally threatened. Fairly numerous, but local and patchy in distribution. Rare in Peru. In Venezuela, most records from S Bolívar. In Brazil, few records S of Paraná.
Bibliography. Armani (1985), Belton (1974, 1985), Fontana *et al.* (2010), Graham *et al.* (1980), Hennessey *et al.* (2003), Klicka *et al.* (2007), McCarthy (2006), Meyer de Schauensee (1952a), Militello & Chebez (2009), Ouellet (1992), Restall *et al.* (2006), Ridgely & Tudor (1989), Sick (1993), Vignini (1985).

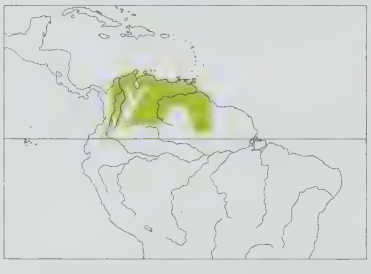
258. Variable Seedeater

Sporophila corvina

French: Sporophile variable **German**: Mohrenpfäffchen **Spanish**: Semillero Variable
Other common names: Black Seedeater, Northern Variable Seedeater

Taxonomy. *Spermophila corvina* P. L. Sclater, 1860, Playa Vicente, Oaxaca, Mexico.
Formerly referred to as *S. aurita*, but type of this name is unidentifiable as it originates from Canal Zone of Panama, where nominate race and *hicksii* interbreed. Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. americana*, *S. murallae* and *S. intermedia*, and has been treated as conspecific with the first two; *S. intermedia* was not thought to belong to this group until seen to hybridize with present species in two different regions of Colombia. From Colombia, proposed race *anchicayae* (described from R Anchicayá, in Valle) is a hybrid between race *hicksii* of present species and race *bogotensis* of *S. intermedia*, and *chocoana* (from Nuquí, in Chocó) is considered inseparable from *hicksii*. Four subspecies recognized.
Subspecies and Distribution.
S. c. corvina (P. L. Sclater, 1860) – S Mexico (S Veracruz and N Oaxaca), Guatemala and Belize S on Caribbean slope to Costa Rica and W Panama.
S. c. hoffmanni Cabanis, 1861 – Pacific slope of Costa Rica and extreme W Panama.
S. c. hicksii (Lawrence, 1865) – Pacific slope of Panama (except extreme W) E through Canal Zone to W Colombia (Córdoba S to Cauca).
S. c. ophthalmica (P. L. Sclater, 1860) – lowlands W of Andes from SW Colombia (Nariño) S to NW Peru (La Libertad).

Descriptive notes. 9·6–11·5 cm; 9·5–12·5 g. Tiny passerine with thick bill approximately as long as it is deep, with distinct rounded culmen. Male nominate race is entirely black, except for white patch at base of primaries, and sometimes a white stripe on mid-line of belly; iris dark brown; bill and legs blackish. Female is brown on head and upperparts to lower back, paler warm buff on rump and uppertail-coverts; upperwing and tail feathers dark brown with warm olive-brown edges, diffuse whitish bases on primaries (indistinct whitish panel on folded wing); paler and buffier below, palest on throat, contrasting narrow brownish breastband; bill dark grey. Juvenile is similar to female; immature male brownish like female, but blackish wings and tail, and extensive and patchy black feathering on breast, crown, face and back. Races differ mainly in plumage of male, only nominate almost all black: *hicksii* has contrasting white rump variably barred with black, well-marked white panel at base of folded primaries, chin black, narrow white band on lower throat continuing as larger white spur on side of neck and surrounding black chin (sometimes with forward extension to malar tract), contrasting broad black breastband, rest of underparts white with variable black splotching on lower breast and especially flanks, thighs blackish (some have black chin area more extensive, extreme examples with entire neck side



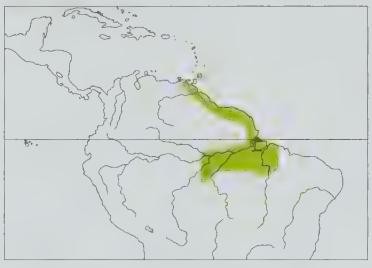
On following pages: 259. Grey Seedeater (*Sporophila intermedia*); 260. Wing-barred Seedeater (*Sporophila americana*); 261. Caqueta Seedeater (*Sporophila murallae*); 262. White-collared Seedeater (*Sporophila torqueola*); 263. Rusty-collared Seedeater (*Sporophila collaris*).

to throat and malar black, these also with white primaries much reduced, rump nearly entirely black); *hoffmanni* is like previous, but throat always all black, and white neck-collar often lacking; *ophthalmica* also resembles *hicksii*, but has narrower black breastband, larger white wing patch, and usually a white lower eye-crescent. Voice. Song a prolonged warble, accelerating from breezy start into a jumble of notes, a sweet, rapid, buzzy "tsiwee tsiwee tsiwee, chee chee chee, twee tweet wee twee, chirr chirr chirr chirr". Call "chiwee" or "tsiwee", or harsher "chur".
Habitat. Inhabits scrub; also forest-edge thickets, weedy fields and roadsides. Occurs from sea-level up to c. 1500 m.
Food and Feeding. Feeds primarily on seeds (*Solanum*, *Paspalum*, *Amaranthus*, *Panicum*, *Spoarbolus*, *Carex*, and *Chaetochloa*), also on berries, and insects. Young fed primarily with grass seeds. Usually forages for grass seeds while on the stem; typically, alights on stem and bends it down to the ground, allowing easier access to seeds. May also forage on ground. In pairs and small groups; often with other seedeaters.
Breeding. Season May–Oct (usually Jul and Aug) in C Panama (Canal Zone) and eggs being incubated in Mar in NW (Bocas del Toro); timing varies from year to year, depending on rainfall, as the species waits for rain to spur grass growth. Nest built by female, a thin-walled cup, placed 0·8–6 m (rarely 9 m) above ground in fork of branch of tree or shrub, woven into branches for support. Clutch 2 eggs, rarely 3, pale greyish with darker grey and brown blotching, this often concentrated at wide end; incubation by female, period c. 12 days; no information on nestling period.
Movements. Resident, with some local movements.
Status and Conservation. Not globally threatened. Fairly common to common in most of range; common to abundant in many parts. Has large range, and no evidence of any no large-scale declines in population.
Bibliography. Binford (1989), Dunning (1993b), Gross (1952), Hilty (2003), Howell & Webb (1995), Klicka *et al.* (2007), McCarthy (2006), Meyer de Schauensee (1952a), Miller *et al.* (1957), Olson (1981d), Ouellet (1992), Ridgway (1901), Russell (1964), da Silva (1999), Stiles (1996), Stiles & Skutch (1989), Weathers (1997), Wetmore *et al.* (1984).

259. **Grey Seedeater**
Sporophila intermedia

French: Sporophile intermédiaire **German**: Einfarbpfäffchen **Spanish**: Semillero Intermedio

Taxonomy. *Sporophila intermedia* Cabanis, 1851, Puerto Cabello, Venezuela.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. corvina*, *S. americana* and *S. murallae*; was not thought to belong in this group until seen to hybridize with *S. corvina* in two different regions of Colombia. Race *insularis* appears to be broadly sympatric with nominate and exhibits constant differences in plumage and biometrics; has recently been proposed as representing a cryptic species; further research required. Proposed race *anchicayae* (described from R Anchicayá, in Valle, in Colombia) is a hybrid between race *bogotensis* of present species and race *hicksii* of *S. corvina*. Proposed race *agustini* (San Agustin, Huila, Colombia) not reliably separable from *bogotensis*, and better merged therein. Three subspecies recognized.
Subspecies and Distribution.
S. i. intermedia Cabanis, 1851 – N & E Colombia (Caribbean coast, lower Magdalena Valley, and *llanos* in E), N Venezuela and Guyana, and N Brazil (Roraima).
S. i. bogotensis (Gilliard, 1946) – W Colombia on W slope of W Andes (E to Cauca Valley).
S. i. insularis (Gilliard, 1946) – Venezuela N of R Orinoco; Trinidad.

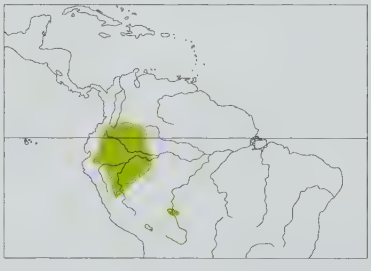


Descriptive notes. 11 cm; 11–16 g. Tiny passerine with thick bill approximately as long as it is deep, with distinctly rounded culmen. Male nominate race has head to neck and entire upperparts medium-grey with blue cast, very indistinct streaking on crown, mantle and back; upperwing and tail blackish, upperwing-coverts and tertials with grey fringes (of same darkness and colour as back), white primary bases (not extending to outer three primaries) forming well-marked white panel on folded wing; belly, vent and undertail-coverts whitish, contrasting with darker grey breast, wing-linings whitish; iris dark brown; bill pinkish-orange; legs blackish. Female is nondescript, buffy brown on crown and nape to lower back, upperwing and tail the same, face also buffy brown but paler and warmer than crown; below, warm pale cinnamon on throat and breast, this colour extending to flanks, but contrasting with paler buffy belly to undertail-coverts; bill blackish. Juvenile resembles female; immature male becomes progressively greyer. Race *insularis* is similar to nominate, but larger, with longer bill, longer tarsus, pale patch on side of neck, and white rump band; *bogotensis* is darker than nominate, has whitish patch on side of neck like previous, larger white primary patch, and grey band across foreneck. Voice. Song a simple and deliberate "gee-gee-gee-gee"; mimicry reported in a song type that begins with "gee-gee-gee..." and extends to rapid succession of mimicked voices of other bird species, also frog (Anura) calls and sound made by squeaky gate. Call "tseep?".
Habitat. Grassland and open shrubby clearings in tropical zone, to 2300 m in Colombia; lower, to 1200 m, in Venezuela. Also in overgrown lots within urban areas, so widely adaptable. In Trinidad in second growth and open areas, mostly low-lying, and in forest edges and foothills.
Food and Feeding. Feeds on seeds of the grass *Panicum*, as well as forbs; also nectar and small arthropods, mainly in dry season, when seeds difficult to come by. Obtains seeds by clinging on stem and reaching forwards or downwards to eat from seedheads. Makes short aerial sallies to catch flying insects. Singly and in pairs; in small flocks outside breeding season.
Breeding. Season May–Oct (rarely slightly earlier and later) in Venezuelan *llanos* and Jun–Sept in Trinidad, thus can breed for much of year, but avoids Dec–Mar dry season. Nest a flimsy cup, made mainly from rootlets and fibres, lined with finer fibres, placed 2–6 m above ground in branch fork of small tree. Clutch 2–3 eggs, cream-coloured with irregular dark brown markings. No other information.
Movements. Resident; appears to make only local movements.
Status and Conservation. Not globally threatened. Common to very common and widespread on mainland; scarce to uncommon in Trinidad. Popular as a cagebird in Trinidad, and numbers there declining, perhaps because of both indiscriminate trapping and habitat destruction.
Bibliography. Armani (1985), Dunning (2008), ffrench (1991), Gilliard (1946), Hilty (2003), Hilty & Brown (1986), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Restall (2002), Restall *et al.* (2006), Ridgely & Tudor (1989), Ridgway (1901), da Silva (1999), da Silva & O'Neill (1986), Stiles (1996), Thomas (1996).

260. **Wing-barred Seedeater**
Sporophila americana

French: Sporophile à ailes blanches **German**: Wechselpfäffchen **Spanish**: Semillero Aliblanco
Other common names: Southern Variable Seedeater

Taxonomy. *Loxia americana* J. F. Gmelin, 1789, Cayenne, French Guiana.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. corvina*, *S. murallae* and *S. intermedia*, and has been treated as conspecific with the first two; *S. intermedia* was not thought to belong to this group until seen to hybridize with *S. corvina* in two different regions of Colombia. Within this group, present species thought to be sister to *S. murallae*. Two subspecies recognized.
Subspecies and Distribution.
S. a. americana (J. F. Gmelin, 1789) – NE Venezuela (Sucre S to Delta Amacuro) E to the Guianas and N Brazil (Amapá and NE Pará); also Tobago.
S. a. dispar Todd, 1922 – middle and lower R Amazon from Manacapurú on N bank and R Juruá on S bank E to Santarém (Brazil).

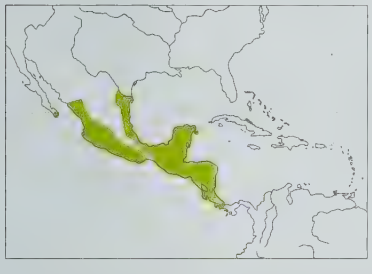


Descriptive notes. 10–11 cm; 10–14 g. A relatively stocky seedeater with large, short and deep bill. Male nominate race has black head contrasting with white band across side of neck running from side of nape to join white submoustachial and throat; upperparts black, variably whitish rump speckled with black; tail black; upperwing black, median and greater upperwing-coverts tipped white (creating two distinct wingbars, lower one usually broader), white at primary bases (forming rectangular white patch on folded wing); below, chin to undertail-coverts white, variable greyish wash on flanks, usually a broken narrow black breastband (some may have only dark wedges on breast sides, with apices towards mid-line of breast); iris dark brown; bill and legs black. Female is nondescript, buffy brown on crown and nape to lower back, upperwing and tail similar in colour to upperparts, face somewhat paler and warmer than crown; below, warm pale cinnamon on throat and breast, this colour extending to flanks, but contrasting with paler buffy belly to undertail-coverts; bill and legs blackish-brown. Juvenile is like female, but with more of a ginger wash below; immature male has body like juvenile, contrasting blackish wings and tail. Race *dispar* larger, with larger white wing patch, and rump more obviously spotted white, female duller overall, being greyish to brownish above and dull whitish below. Voice. Song pleasant and musical, although nasal, and generally lasting for several seconds; consists of rapid trills and twittering sounds accented by pure whistles, sometimes tapering off to a chatter. Call "cheeeu!". Also gives repetitive but pleasant "titty-ootaw", perhaps a call note.
Habitat. Forest edge and second growth, often near mangrove swamps. Lowlands, mainly on coastal plain, to 50 m; also on grassy river islands.
Food and Feeding. Feeds on seeds of grasses, sedges (Cyperaceae) and weeds, with preference for *Paspalum* and *Panicum maximum*; also takes fruits and flower buds, and possibly some insects. Has been observed to forage on *Cecropia* fruit, and also on Müllerian bodies (containing glycogen) from vegetative structures on these trees. Clings to plant stems to reach seeds; forages also in trees. In pairs and small flocks.
Breeding. Recorded in Jan. Nest resembles that of *S. intermedia*, made of stems and tendrils, lined with fine black fibres that create "wreath" around rim; one nest was in crotch of branch c. 1·2 m up cocoa tree (*Theobroma cacao*), another was c. 13·5 m up immortelle tree (*Erythrina poeppigiana*). Female builds nest and incubates. No further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to rare; probably most common in Guyana. A 1934 report of nominate race from Chacachacare I (off NW Trinidad) considered of doubtful validity. In Guyana, and probably elsewhere, this species is under strong pressure from songbird-trapping activities of local people.
Bibliography. Armani (1985), Dorn (1980b), ffrench (1991), Griscom & Greenway (1941), Klicka *et al.* (2007), McCarthy (2006), Meyer de Schauensee (1952a), Ouellet (1992), Restall *et al.* (2006), Ridgely & Tudor (1989), Stiles (1996), Stuart (2000), de Vasconcelos (2004).

261. **Caqueta Seedeater**
Sporophila murallae

French: Sporophile du Caqueta **German**: Caquetapfäffchen **Spanish**: Semillero de Caquetá

Taxonomy. *Sporophila murallae* Chapman, 1915, La Muralla [= Morelia], 600 feet [c. 180 m], Caquetá, Colombia. Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. corvina*, *S. americana* and *S. intermedia*, and has been treated as conspecific with the first two; *S. intermedia* was not thought to belong to this group until seen to hybridize with *S. corvina* in two different regions of Colombia. Within this group, present species thought to be sister to *S. americana*. Monotypic.
Distribution. SE Colombia (in upper R Amazon region), E Ecuador and NE Peru, also adjacent W Brazil; recently recorded NE Bolivia (N Beni).



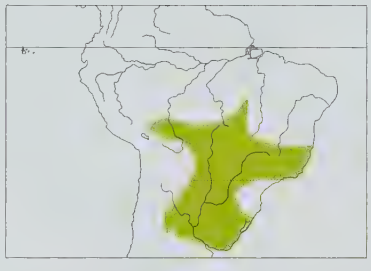
Descriptive notes. 10 cm. A relatively stocky seedeater with short, deep bill. Male has black head contrasting with white band across side of neck running from side of nape to join white submoustachial and throat, short black malar stripe; upperparts black, variably whitish rump speckled with black (on some rump entirely black); tail wholly black; upperwing black, median and usually greater coverts tipped white (two narrow but distinct white wingbars; on some individuals lower bar absent), white at primary bases (forming rectangular white patch on folded wing); chin to undertail-coverts white, side of breast black, narrow black

breastband (sometimes broken in centre), variable greyish wash on flanks; some individuals have black or greyish chin; iris dark brown; bill and legs black. Female is nondescript, buffy brown on crown, nape, mantle and back, upperwing and tail also buff-brown, face similar but paler and warmer than crown; warm pale cinnamon on throat and breast, this colour extending to flanks, contrasting paler buffy belly to undertail-coverts; almost whitish on centre of belly, vent and sometimes breast centre; bill and legs blackish. Juvenile undescribed. Voice. Song a pleasant warble, not hurried, but relatively quick, "tweet weet twa tweet, tw-weet twaa tweet...", continuing for several seconds. Call "cheeeu!".
Habitat. Lowland riverine scrub, also openings at edge of forest and secondary forest; also pastureland with isolated trees. Tropical zone to 1200 m.
Food and Feeding. Feeds on seeds of grasses and weeds, with preference for *Paspalum* and *Panicum maximum*. Usually in pairs; sometimes associated with other seedeaters.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon, but widespread. Recently recorded for first time in Bolivia. Degradation of primary forest may be helping this species to spread, as it favours forest openings and edge of open secondary forest.
Bibliography. Chapman (1915), Guevara *et al.* (2008), Herrera & Maillard (2007), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Stiles (1996).

262. White-collared Seedeater
Sporophila torqueola

French: Sporophile à col blanc **German**: Braunbürzelpfäffchen **Spanish**: Semillero Cuelliblanco
Other common names: Collared/Cinnamon-rumped Seedeater (*torqueola* and *atriceps* combined); Morellet's/White-collared Seedeater (*sharpei*, *morelleti* and *mutanda*)

Taxonomy. *Spermophila torqueola* Bonaparte, 1850, Cuidad México, Mexico.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Races *sharpei*, *morelleti* and *mutanda* sometimes treated together as representing a separate species; no intermediates known between these and the two remaining races. Five subspecies generally recognized.
Subspecies and Distribution.
S. t. atriceps (Lawrence, 1867) – Pacific lowlands of Mexico from C & S Sinaloa and W Durango S to Nayarit and N Jalisco; S Baja California.
S. t. torqueola (Bonaparte, 1850) – C Mexico from Jalisco and Guanajuato E to Morelos and W Puebla, S to Colima, Michoacán, Guerrero and W & S Oaxaca.
S. t. sharpei Lawrence, 1889 – extreme S USA (lower R Grande Valley, in S Texas) and NE Mexico (Nuevo León and Tamaulipas S through E San Luis Potosí to N Veracruz).
S. t. morelleti (Bonaparte, 1850) – E Mexico (N Veracruz) S on Caribbean slope (including Mujeres I, off NE Quintana Roo), and on Atlantic slope from El Salvador, to extreme W Panama.
S. t. mutanda Griscom, 1930 – S Mexico (S Chiapas) S to El Salvador.



Descriptive notes. 9·5–11·2 cm; 6·3–12 g. Small to tiny seedeater. Male nominate race has blackish-brown head contrasting with white band across side of neck running from side of nape to join whitish submoustachial area and throat; nape and upperparts blackish-brown, contrasting cinnamon rump, white on throat extending as white spur to side of neck (but lacks full collar separating cap from back); upperwing and tail blackish, base of primaries white (creating rectangular white panel on folded wing); below, has well-marked narrow black breastband, with rest of underparts pale cinnamon, palest on belly and continuing to undertail-coverts; iris blackish; bill and legs blackish. Female is very nondescript, entirely buffy brown and unstreaked above, lacking any distinctive pattern, pale cinnamon below, darkest on breast and flanks, paler creamy buff on chin, belly and crissum; bill dark horn-coloured. Juvenile is like female; immature male gradually gains adult pattern, brownish back, wings and tail the last to become black (a black-crowned and brown-backed individual is a young male). Races differ mainly in plumage tones and pattern of male, "*morelleti* group" males tending to have full white hindneck-collar and both sexes having obvious wingbars: *atriceps* male is like nominate, but back browner (rarely blackish), wing patch smaller; *morelleti* has head and side of face black, contrasting white crescent below eye, full white collar across neck side and nape (separating black cap from black mantle), upperparts black, rump greyish or buff-white, bold white wingbars, large white primary patch, noticeably white-edged tertials, wide black breastband separating white throat from white underparts; *mutanda* is similar to previous, but generally some black areas on throat; *sharpei* is variable, male with varying amounts of greyish-olive to greyish-buff on head and upperparts, wing pattern similar to that of *morelleti*, often black flecks on breast and collar, rump greyish-buff, side of neck usually whitish, underparts buff. Voice. Song high-pitched and canary-like, a clear "sweet sweet sweet cheer cheer cheer" or "sweet sweet sweet cheer cheer cheer chee swee swee r r r r r"; variable. Call a double "tick tick", also a soft "che" or "chip".
Habitat. Open grassy areas, pastures, roadsides, weedy fields, moist savanna, and marshlands with tall grasses; often roosts in tall grasses, and sometimes cat-tails (*Typha*) at edges of marshes. Avoids second-growth areas where encroachment of woody vegetation. Sea-level to 2000 m.
Food and Feeding. Eats mainly grass seeds, augmented with a few berries and insects. Will jump into air to catch flying insects. Usually in pairs; outside breeding season in flocks of up to several hundred individuals, often with other seed-eating species.
Breeding. Commences in late Mar/Apr and continues into summer in S Texas; begins in Apr in N Central America. Nest built by female, taking 5–6 days, a thin-walled cup with outer layer of cobwebs, filled with rootlets, fibres and grasses, lined with horsehair if available, or with finer fibres, placed 1–2 m (rarely to 3 m) up, sometimes over running water, in dense shrub or coarse vegetation. Clutch 2–4 eggs, pale blue to greenish with brown or blackish spotting and blotching; incubation by female, period c. 13 days; chicks fed by both parents, nestling period 10–11 days. Rare host of Brown-headed Cowbird (*Molothrus ater*).
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common to fairly common; abundant in many parts of its range. Has recently colonized S Baja California; unclear whether this is natural or through introduction.
Bibliography. Armani (1985), Arnold (1980), Binford (1989), Dunning (1993b), Eitniear (1997, 2004), Howell & Webb (1995), Meyer de Schauensee (1952a), Miller *et al.* (1957), Ouellet (1992), Ridgway (1901), Rowley (1962), Russell (1964), Selander & Giller (1959), Stiles & Skutch (1989), Wetmore *et al.* (1984), Woodin *et al.* (1999).

263. Rusty-collared Seedeater
Sporophila collaris

French: Sporophile à col fauve **German**: Erzpfäffchen **Spanish**: Semillero Acollarado

Taxonomy. *Loxia collaris* Boddaert, 1783, Angola; error = Rio de Janeiro, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Molecular-genetic data indicate that present species belongs in a clade with *S. luctuosa*, *S. nigricollis* and *S. caerulescens*. Geographical variation possibly partly clinal; in E of range nominate race may form a cline with *melanocephala*, plumage becoming more colourful from N to S; further study needed. Three subspecies recognized.
Subspecies and Distribution.
S. c. ochrascens Hellmayr, 1904 – Bolivia (lowland La Paz, Beni and Santa Cruz) and SC Brazil (N Mato Grosso S to W São Paulo).
S. c. melanocephala (Vieillot, 1817) – SW Mato Grosso S through Paraguay to Argentina (S to La Rioja, Santiago del Estero, Córdoba and C Buenos Aires), also SE Brazil (Rio Grande do Sul) and Uruguay.
S. c. collaris (Boddaert, 1783) – E Brazil from S Goiás, Minas Gerais and extreme SE Bahia S to Rio de Janeiro.

Descriptive notes. 12 cm; 7·5–14 g. A comparatively large and strikingly marked seedeater with relatively long and broad tail; typical short, thick bill with rounded culmen. Male nominate race has black head, white patch above lores and another below eye, broad white partial neck-collar; mantle and back blackish-grey, scapulars with broad paler edges, lower back and rump pale buff, contrasting strongly with blackish back and black tail; upperwing black, primary bases white (forming big bold white patch on folded wing), narrow whitish wingbars; throat white, narrow black breast-band extending to side of neck; below breast-band entire underparts to undertail-coverts pale buffish; some birds in extreme NE part of range essentially black and white, with grey rump, white collar and white underparts; iris dark brown; bill and legs black. Female is duller than male, but with "ghost pattern" of latter: warm brown above and on face, distinct pale patch below eye (as on male), brown wings with two distinct buffy wingbars; below, strikingly whitish throat, contrasting with tawny-buff underparts; bare parts as for male. Juvenile resembles female. Race *melanocephala* is brighter than nominate, neck-collar cinnamon-tawny, rump tawny, wingbars cinnamon, underparts tawny-cinnamon; *ochrascens* is similar to previous, but upperparts olive-grey to brownish, lighter rust-yellow on neck side and underparts, and cream-coloured on lower breast. Voice. Song a rapid warble that ascends and descends, mixed with twittering sounds and often incorporating imitations of other species, e.g. anis (*Crotophaga*), elaenias (*Elaenia*), tody-flycatchers (*Todirostrum*). Call a nasal "ghep" or sharper "tchep".
Habitat. Moist or flooded grassland and shrubby marshland, also open country adjacent to rivers or lakes; generally associated with marshes with tall vegetation. Closely associated in particular with marshes of the giant sedge *Cyperus giganteus*. Sea-level to 500 m.
Food and Feeding. Seeds; also eats insects. Forages largely on grass seeds while seeds still on stem; rarely drops to ground to forage, tending instead to perch on vegetation while feeding. Usually in pairs or small groups.
Breeding. Season early Nov to Apr in Argentina (Formosa) and birds in breeding condition during Nov–Mar and inactive during May in SE Brazil (Rio Grande do Sul), indicating breeding in austral spring–summer. Nest built by female, a cup 5 cm in diameter, made from fine fibres and dry vegetation, attached usually 1·5–2 m above ground to low shrub, often over water. Clutch 2–3 eggs, greenish-blue or whitish-green, with chestnut, brown and grey markings concentrated around wide end; incubation by female, sometimes fed at or near nest by male, period 12–13 days; chicks fed by both parents, nestling period 9–12 days.
Movements. Resident; some local movements.
Status and Conservation. Not globally threatened. Common to fairly common in varied open marshy or wet-grassland habitats. Commonly captured for the cagebird trade.
Bibliography. Armani (1985), Belton (1985), Campagna *et al.* (2010), Canevari *et al.* (1991), Dubs (1992), Facchinetti *et al.* (2008), Kirwan (2007), Kirwan *et al.* (2004), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), McCarthy (2006), Meyer de Schauensee (1952a), Ouellet (1992), de la Peña (1987), Ridgely & Tudor (1989), Sferco & Baldo (1995), Sick (1993), da Silva (1999), Storer (1989b).

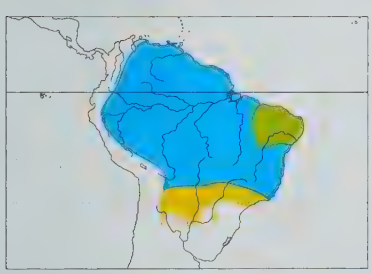
264. Lesson's Seedeater

Sporophila bouvronides

French: Sporophile faux-bouvron **German**: Weißbartpfäffchen **Spanish**: Semillero de Lesson

Taxonomy. *Pyrrhula bouvronides* Lesson, 1831, no locality = Trinidad.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. lineola* and has been treated as conspecific. Proposed geographical race *restricta*, known from a single specimen from Magdalena Valley, in Colombia, lies well within range of variation of the species elsewhere and does not merit recognition. Monotypic.
Distribution. Breeds N Colombia (N & E of Andes), W, C & N Venezuela, the Guianas, Trinidad and Tobago. Most migrate S to N Amazonia in Brazil, SE Colombia, E Ecuador, NE Peru and Bolivia (Beni and Santa Cruz).



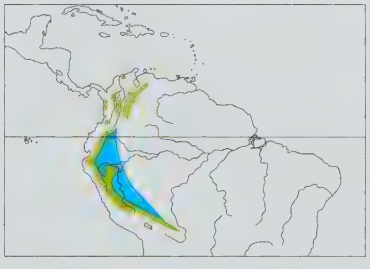
Descriptive notes. 10–11 cm; 8–11 g. Tiny seedeater with thick bill approximately as long as it is deep, with distinct rounded culmen. Male has matt black head to throat, large white triangular patch over lower ear-coverts to submoustachial region; upperparts entirely black, except for narrow band of white on rump; upperwing and tail black, white on primary bases (forming distinct white patch on folded wing); breast white with diffuse black markings, more solid black side of breast, rest of underparts whitish; iris dark brown; bill and legs black. Female is dull and nondescript, olive-brown above, paler below, with no distinctive features; below, buffy on breast, paler creamy on throat, and palest on lower breast to undertail-coverts; upper mandible dark, lower mandible horn-coloured, legs blackish. Juvenile undescribed. Voice. Song begins with a few harsh notes and then changes into melodious notes, "chaw, chee childedee-chea-chea-chea" or "jaaaw, geee, chutchutchutjeet"; in Trinidad and Tobago described as a long rolling trill followed by chattering; song in Venezuela a mechanical trill. Call "chip".
Habitat. Grassy clearings and shrubby areas, often near water in tropical zone. Likes edges of woodland when breeding, also openings in forest. Sea-level to 1000 m.
Food and Feeding. Mostly grass seeds. Forages in typical manner, gripping grass stalk while extracting seeds. May forage also on ground. In flocks outside breeding season.
Breeding. Season Apr–Nov. Territorial; male sings persistently from perches on small trees or larger bushes. Nest a loose cup of dry grasses and rootlets, placed 5–10 m above ground in fork of branch in sapling, or towards outer branches of larger tree. Clutch 2–3 eggs, whitish with many brown and blackish markings; chicks fed by both sexes. No other information.
Movements. Highly migratory. After breeding, most vacate N breeding grounds and spread throughout N Amazonia in non-breeding season, moving as far S as N Bolivia; present in non-breeding quarters Dec–Jun, some returning N earlier (from Apr). Vagrant in extreme E Panama.
Status and Conservation. Not globally threatened. Uncommon to fairly common within breeding range. Locally abundant, e.g. in W Venezuela (parts of SW Portuguesa).
Bibliography. Beebe (1917), ffrench (1991), Herrera & Vidoz (2009), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Restall *et al.* (2006), Ridgely & Tudor (1989), Schwartz (1975), Whitney *et al.* (1994).

265. Lined Seedeater

Sporophila lineola

French: Sporophile bouveron **German**: Diamantpfäffchen **Spanish**: Semillero Overo

Taxonomy. *Loxia lineola* Linnaeus, 1758, Asia; error = Bahia, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Forms a superspecies with *S. bouvronides* and has been treated as conspecific. Monotypic.
Distribution. Breeds in NE Brazil (Maranhão and Piauí E to Rio Grande do Norte and Alagoas); and S of Amazon Basin in SE Bolivia (Tarija, Chuquisaca and Santa Cruz), Paraguay, N Argentina (S to Tucumán, Santiago del Estero and Santa Fe; recently also in Misiones) and S Brazil (C Mato Grosso do Sul E to N Rio de Janeiro, and S to C São Paulo; possibly also Paraná, Santa Catarina and Rio Grande do Sul). Non-breeding visitor throughout N South America N to E Colombia, Venezuela, the Guianas, also E Ecuador, NE Peru and much of Brazil.



Descriptive notes. 10–11 cm; 7·5–12 g. Tiny seedeater with thick bill approximately as long as it is deep, with distinctly rounded culmen. Male has most of head and throat black, wide white stripe along mid-line of crown, large white triangular patch over lower ear-coverts to submoustachial region, bordered below by black line; upperparts black, narrow band of white on rump; upperwing and tail black, white on primary bases (forming distinct white patch on folded wing); underparts whitish, black thigh; iris dark brown; bill and legs black. Female is dull and nondescript, brownish-olive above, paler below, no distinctive features; buffy on breast, paler creamy on throat, and palest buff on lower breast to undertail-coverts; upper mandible dark, lower mandible horn-coloured, legs blackish. Juvenile undescribed. Voice. Songs differ geographically: in E of range (in *caatinga*) a trill followed by "tuweet" or a few introductory "tic" notes followed by a trill, "dit dit dit drdrdrdrdrdr"; in W & S of range song described as a pleasant resonating and warbling trill, "dididididdee" or "krrrrrrrrr", followed by one or more high-pitched "chip" notes. At times song simplified to a short rattle. Call "check", also a dull trilling "ki-rik" and a strident and repeated whistled "peeu".
Habitat. Breeds at edge of *chaco* woodland, *caatinga*, xeric forests and other patches of forest, both in open areas with grass and in areas adjacent to shrubby forest and second growth. In non-breeding period open grassy savanna, shrubby clearings and semi-open areas with tall grass, often near water. Tropical zone, to 500 m; migrants as high as 1500 m.
Food and Feeding. Largely seeds; prefers grass seeds, and has been seen to feed on *Echinochloa polystachya*, *Paspalum urvillei* and *Paspalum notatum* in NE Argentina. Forages on ground, as well as while clinging to grass stalks and other vegetation. Usually in pairs during breeding period; in small flocks at other times.
Breeding. Has nested in May in NE Brazil (Piauí); season Feb–Mar in NW Argentina; Nov–Apr (peak in Jan) in SE Brazil (São Paulo). Cup-shaped, thin-walled nest made from thin grass roots (including those of exotic species) bound together with spider webs, sometimes made from vegetable fibres, placed c. 0·8–11 m above ground in branch fork in shrub or tree, including exotic species. Clutch 2 or 3 eggs, in São Paulo white with light and dark brown spots and blotches, these often concentrated at large end, in Argentina eggs described as greenish-grey with darker spots; incubation by female, period very short, 10–12 days; chicks fed by both sexes, nestling period 9–13 days. For 63 nests in São Paulo, survival during incubation stage 70% and during nestling stage 56%, with overall nesting success 40%.
Movements. Austral migrant, breeds S of equator, and spends non-breeding period as far N as Venezuela. Present in C & W Amazonas all year, but unclear if a resident population or if individuals from different populations visit at various times of year. Traditionally considered to consist of two populations, one breeding in Argentina, Bolivia, Paraguay and SE Brazil which winters in Peru, Ecuador, Colombia and N Brazil, the other breeding in *caatinga* of Brazil and wintering in Venezuela and the Guianas. In E Brazil (Espírito Santo and Paraná), arrives in Dec to breed and disappears in Mar–Apr; similar timing observed in Argentina, while in NE Brazil there is an influx of breeders from May onwards.
Status and Conservation. Not globally threatened. Fairly common, rather local in occurrence. Uncommon non-breeder in French Guiana. Has relatively large breeding range. No particular habitat problems known; some woodlands in Chaco region and other sections of breeding distribution are being converted to soybean fields, but any effects of this habitat alteration on the species not known. In São Paulo study, factors such as lack of selectivity in choice of nesting tree (many of which were exotic) and utilization of exotic grasses in nest construction (mostly rootlets) allow it to thrive in human-modified habitats.
Bibliography. Areta & Almirón (2009), Armani (1985), Canevari *et al.* (1991), Carrano *et al.* (2002), Dubs (1992), Klicka *et al.* (2007), Marcondes-Machado (1998), McCarthy (2006), Meyer de Schauensee (1952a), de Oliveira *et al.* (2010), Ouellet (1992), de la Peña (1987), Restall *et al.* (2006), Ridgely & Tudor (1989), Schwartz (1975), Sick (1993), da Silva (1995, 1999), Thomas (1996).

266. Black-and-white Seedeater

Sporophila luctuosa

French: Sporophile noir et blanc **German**: Trauerpfäffchen **Spanish**: Semillero Negriblanco

Taxonomy. *Spermophila luctuosa* Lafresnaye, 1843, Bogotá, Colombia.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Molecular-genetic data indicate that present species belongs in a clade with *S. collaris*, *S. nigricollis* and *S. caerulescens*. Monotypic.
Distribution. Andes from W Venezuela S through Colombia, Ecuador and Peru to Bolivia (La Paz, Cochabamba and Santa Cruz).

Descriptive notes. 11 cm; average 12·5 g (Peru). Male has head to breast black, thin but noticeable white crescent below eye; upperparts, including upperwing and tail, black, bases of primaries white (forming bold white patch on folded wing); black of breast stops abruptly and neatly, rest of underparts to undertail-coverts white, some black extending down flanks; wing-linings white, sometimes showing as white stripe at bend of wing; iris dark brown; bill entirely blue-grey; legs blackish. Female is nondescript, warm buffy brown on crown and upperparts, wings and tail also buff-brown like upperparts; below, throat and breast a similar warm buff-brown, hardly contrasting with face, this colour extending to flanks and contrasting with paler buff belly and vent; crissum darker than belly, similar to flanks; bill and legs blackish. Juvenile resembles female; immature male variable, some brownish like female (but sing, and are territorial), others intermediate between brown plumage and black-and-white plumage of adult male. Voice. Song rather unusual-sounding, not melodic, almost reminiscent of an icterid, 2 harsh notes followed by gurgling notes, and sometimes even harsher, shrieking vocalizations like those of a parrot (Psittacidae), "guak-cheeo chpchpchpchpchp". Females sing a temporally restricted and unstructured song, very different from that of male. Calls include nasal "nhhheep" and harsher "phhhp!".
Habitat. Grassy areas at forest edge, also roadside pastures and shrubbery. Subtropical zone on lower Andean slopes at 1200–3100 m, rarely lower, to 300 m.
Food and Feeding. Seeds; appears to some extent to be somewhat dependent on bamboo (*Chusquea*) seeding. Forages in manner typical of genus, clinging to grass stems and feeding on seeds while still on stem; does not eat seeds on ground. Forages sometimes in pairs, more often in small flocks of up to 30 individuals, particularly in non-breeding period; tends to associate with other members of genus.
Breeding. In Colombia males in breeding condition during Sept (Santander and Boyaca) and juveniles present in Apr (Antioquia). Said to be loosely colonial in Venezuela. No other information.
Movements. Little information. Possibly engages in seasonal elevational movements; perhaps to some extent nomadic, wandering in search of seeding grass.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common, and patchy in distribution. Has relatively large range. This species' liking for second-growth edge may lead to its having more habitat as montane forests are disturbed or degraded.

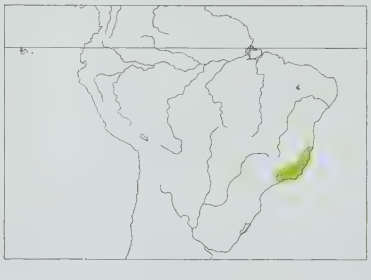
White-throated Seedeater (*Sporophila albogularis*); 271. White-bellied Seedeater (*Sporophila leucoptera*); 272. Parrot-billed Seedeater (*Sporophila peruviana*).

267. Yellow-bellied Seedeater

Sporophila nigricollis

French: Sporophile à ventre jaune **Spanish**: Semillero Ventriamarillo
German: Gelbbauchpfäffchen
Other common names: Black-necked Seedeater; Hooded Seedeater ("*S. melanops*")

Taxonomy. *Pyrrhula nigricollis* Vieillot, 1823, Brazil. Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Molecular-genetic data indicate that present species belongs in a clade with *S. collaris*, *S. luctuosa* and *S. caerulescens*. Possibly conspecific with *S. ardesiaca*. Proposed taxon *S. melanops*, known only from one adult male collected in 1823 on E bank of R Araguaia (extreme WC Goiás), in SC Brazil, is believed to have been a variant of present species or a hybrid between it and a congener. Three subspecies recognized.
Subspecies and Distribution.
S. n. nigricollis (Vieillot, 1823) – S Costa Rica and Panama to N, W & E Colombia and probably E Ecuador, E through Venezuela to Suriname, including S Lesser Antilles (Carriacou, Grenada), and Trinidad and Tobago; EC & E Brazil S to Mato Grosso and São Paulo, extreme E Bolivia (E Santa Cruz) and NE Argentina (Misiones).
S. n. vivida Hellmayr, 1938 – SW Colombia (Nariño) and W Ecuador.
S. n. inconspicua Berlepsch & Stolzmann, 1906 – Peruvian Andes S on W slope to Lambayeque and on E slope to Cuzco.



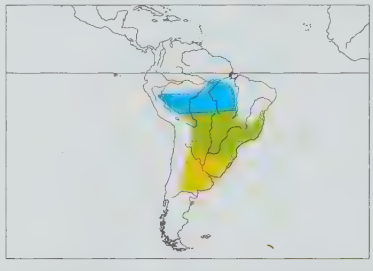
Descriptive notes. 8·5–10·3 cm; 8·5–11·2 g. Typical seedeater, tiny and with thick bill approximately as long as it is deep and with distinct rounded culmen. Male nominate race somewhat variable; has head to nape and down to breast black, upperparts dull olive, inconspicuous darker streaking on back; upperwing and tail brownish, upperwing-coverts and tertials widely fringed olive (like back), edges of rectrices a similar olive colour; below, black of breast stops abruptly and neatly, rest of underparts pale yellowish, often with some blurred spotting on flanks; wing-linings pale yellowish; some birds have olive areas replaced by grey, and underparts whitish; iris dark brown; bill blue-grey; legs blackish. Female is nondescript, warm buffy brown on most of head, nape and mantle to lower back, with wings and tail buff-brown like upperparts; throat and breast a similar warm buff-brown, hardly contrasting with face, this colour extending to flanks and contrasting with paler buff belly and vent; crissum darker than belly, similar to flanks; bill and legs blackish. Juvenile is like female, but more evenly coloured, with warmer, cinnamon wash below; immature male similar to female, but with blackish feathers on face and throat. Race *vivida* is greener above and brighter yellow below than nominate; *inconspicua* is like nominate, but black of hood restricted to foreparts of head, and bib. Voice. Male song, often from tree, "seee seeuu se seeuu seeoo tsr-r-r", somewhat like that of *S. torqueola*, but shorter and rather burry; also described as "sweet", but ending with two buzzy phrases, "seewee-seewee-seewee", etc. Calls include dry "chip" notes.
Habitat. Grassy areas. Found in open *milpas* (fields cultivated rotationally, with fallow periods of several years) and other disturbed areas, mostly agricultural; also weedy old fields. Lowlands to 2500 m, mostly below 2000 m.
Food and Feeding. Diet almost exclusively grass seeds. Often sits on one head of grass and feeds from another, or bends seedhead to ground, where it can be easily reached. Often in small flocks, sometimes containing more than 20 individuals, especially outside breeding period.
Breeding. Season Jul–Sept in Panama; nesting reported throughout year, but varying regionally, in Colombia. Apparently monogamous. Nest a woven cup of grasses and fibres, held together by twigs and spider webs, generally built close to ground (below 1 m), usually in bush or tree. Clutch 2 eggs, occasionally 3, pale greenish-buff with brown spots. No other information.
Movements. Resident and nomadic. Dispersive or nomadic during periods of drought, when grass seeds more difficult to find.
Status and Conservation. Not globally threatened. Locally common; common on Pacific slope throughout range. Although this species is popular as a cagebird, trapping for trade seems not to have led to any significant decreases in its numbers. Proposed taxon *S. melanops* listed as Critically Endangered, but now reckoned to be a variant of present species or perhaps a hybrid; known only from type specimen, dated Oct 1823, from E Brazil; searches in area of type locality, along R Araguaia floodplain, most recently in Dec 2008 to Jan 2009 and Jul 2010, were unsuccessful.
Bibliography. Alderton (1961), Armani (1985), ffrench (1965, 1991), Hilty & Brown (1986), Hirschfeld (2007), Howell & Webb (1995), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Lowen *et al.* (1997), McCarthy (2006), Mees (1968), Meyer de Schauensee (1952a), Ouellet (1992), Restall (2005a), Restall *et al.* (2006), Ridgely & Gwynne (1989), da Silva (1999), Stiles & Skutch (1989), Thomas (1996), Wetmore *et al.* (1984).

268. Dubois's Seedeater

Sporophila ardesiaca

French: Sporophile de Dubois **German**: Duboispfäffchen **Spanish**: Semillero de Dubois

Taxonomy. *Spermophila ardesiaca* A. J. C. Dubois, 1894, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Taxonomic status of present species not clearly understood: seems to be very closely related to *S. nigricollis*, and possibly conspecific, perhaps even a morph; supposed ranges of the two apparently overlap broadly, and they have syntopic breeding distributions; songs reported as essentially identical, suggesting that they are the same species. More research required. Monotypic.



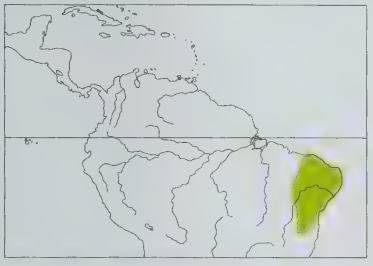
Distribution. SE Brazil in extreme SE Bahia, Espírito Santo, extreme E Minas Gerais and Rio de Janeiro.
Descriptive notes. 11 cm. Male has head to nape and down to breast black, upperparts greyish, inconspicuous darker streaking on back; upperwing and tail brownish, upperwing-coverts and tertials widely fringed greyish (like back); black of breast stops abruptly and neatly, rest of underparts white, often with blurred dark spotting on sides and flanks, wing-linings white; iris dark brown; bill blue-grey; legs blackish. Female is nondescript, warm buffy brown on crown, nape and upperparts, wings and tail similarly buff-brown; below, throat and breast similar warm buff-brown, hardly contrasting with face, this colour extending to flanks and contrasting with paler buff belly and vent; crissum darker than belly, similar to flanks; bill dusky. Juvenile apparently undescribed. Voice. Song a loud and melodious warble with some doubled notes and an accented or different ending, "tweew-tweew, chu-chu, tweeta-cheww-pheeéééé"; apparently similar to, if not identical to, that of local populations of *S. nigricollis*. Call a high-pitched "tiip".
Habitat. Shrubby and grassy clearings, and roadsides; sea-level to 800 m.
Food and Feeding. Diet largely grass seeds. Forages mostly while clinging to grass stem. Found in small flocks, not uncommonly with *S. nigricollis*.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common; rather poorly known. Research required in order to confirm this seedeater's taxonomic status, enabling appropriate conservation management to be determined.
Bibliography. Armani (1985), Klicka *et al.* (2007), McCarthy (2006), Ouellet (1992), Ridgely & Tudor (1989), Sick (1962).

269. Double-collared Seedeater

Sporophila caerulescens

French: Sporophile à col double **German**: Schmuckpfäffchen **Spanish**: Semillero Corbatita
Other common names: Screaming Seedeater

Taxonomy. *Pyrrhula caerulescens* Vieillot, 1823, Brazil. Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Molecular-genetic data indicate that present species belongs in a clade with *S. collaris*, *S. luctuosa* and *S. nigricollis*; visual similarity suggests that it may be closest to *S. albogularis*, but latter was not included in that study. Race *hellmayri* formerly known as *ornata*, but that name invalid, as preoccupied. Three subspecies recognized.
Subspecies and Distribution.
S. c. yungae Gyldenstolpe, 1941 – C Bolivia (La Paz, S Beni and Cochabamba).
S. c. caerulescens (Vieillot, 1823) – SE & E Bolivia, SC & SE Brazil S through Paraguay, Argentina (S to Mendoza and La Pampa) and Uruguay.
S. c. hellmayri Wolters, 1939 – S Bahia, in E Brazil.



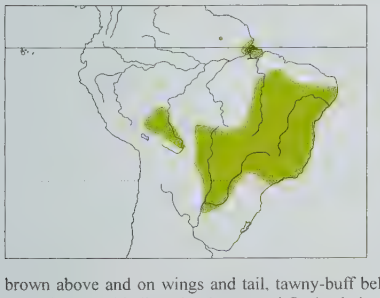
Descriptive notes. 11 cm; 7·4–12·5 g. Typical seedeater, tiny, with thick bill approximately as long as it is deep and with distinct rounded culmen. Male nominate race has crown and face lead-grey, becoming darker, nearly black, on forehead and moustachial region, with crown diffusely streaked, small white crescent below eye, white submoustachial area separating blackish face from blackish upper throat; upperparts, including tail, warmer olive-brown, upperwing plain greyish-olive; lower throat and upper breast white with narrow but bold blackish central breastband, grey of face continuing down to side of breast; otherwise whitish below, grey spotting on flanks; some males have yellowish underparts, apparently a rare but regular variation; iris dark brown; bill yellowish to greyish; legs blackish. Female is nondescript, warm buffy brown on crown, nape and upperparts, wings and tail buff-brown like upperparts; breast a similar warm buff-brown, contrasting with paler throat, darker coloration extending to flanks and contrasting with paler buff belly and vent; crissum darker than belly, similar to flanks; in fresh plumage may have narrow cinnamon-brown wingbars; bill dark, with yellowish-horn lower mandible (bicoloured bill can be a good way to identify females of this species). Juvenile resembles female. Race *yungae* male is paler-headed than nominate, greyish on crown and nape, with blackish restricted largely to lores; *hellmayri* male is distinctive, with black more extensive on forepart of head. Voice. Song loud and varied, composed of variable and jumbled notes, peak sound often half-way or more through song (making ending sound like an afterthought), "jew, jitit-jew-jew, jitit" or "jewle, jewle, jewle, jewle-jéé-jewlo, jewlo-tshrr"; much geographical variation. Captive females also known to sing. Call "tslit" or "tsri".
Habitat. Forest edge, shrubby openings, secondary growth, disturbed *cerrado* habitat, and old-field habitats where some trees or taller shrubbery present; also agricultural areas, towns and roadsides.
Food and Feeding. Diet various grass seeds, including those of introduced forage grasses for cattle. In São Paulo (Brazil) young fed with seeds of the exotic grass *Brachiaria*. Forages both on ground and while perched on vegetation. Usually singly or in pairs; during non-breeding season may forage in small flocks.
Breeding. Season mainly Oct–Feb; Dec–May in SE Brazil, and possibly in all months in N part of range; on average nests later (waiting for seeding of grass to occur) than most other bird species in range. Nest a cup made from dry grass roots and spider webs, walls thin (nest contents visible through side), mean outside diameter 6·7 cm, external height 4·8 cm, placed often less than 50 cm from ground, but sometimes as high as 6 m (averaging 2·4 m), in shrub, short tree or hedge, or shorter vegetation, various plant species used, with apparently no specific preferences. Clutch 3 eggs, 2 in N of range, whitish, cream or palest green with brown, grey and blackish markings, these evenly distributed or sometimes denser around wide end; incubation strictly by female, period 13 days; chicks fed by both sexes, nestling period 12–15 days.
Movements. Incompletely known. Some, perhaps many, populations apparently resident. S populations retreat N in winter; similarly, in N of range more common in austral winter, and in E Peru and across much of C Brazil evidently present only during winter months. Vagrants recorded in NW Brazil (N Amazonas). More work required in order to confirm and describe movements.
Status and Conservation. Not globally threatened. Common to abundant in much of range; generally more numerous than its congeners. Has large breeding distribution. This species' preference for forest edge, second growth and similar areas perhaps means that suitable habitat for it is increasing as forest becomes ever more fragmented. Further, it has adapted well to anthropogenic disturbances and, moreover, it thrives on seeds of grasses introduced for cattle grazing; this adaptability has enabled it to spread into new areas and habitats. This is the most common bird kept in captivity in much of Brazil, and impact of trapping needs to be kept in mind with regard to the species' numerical status.
Bibliography. Alabarce (1987), Armani (1985), Belton (1985), Campagna *et al.* (2010), Coimbra-Filho & Teixeira (1983), Dubs (1992), Francisco (2006), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), McCarthy (2006), Meyer de Schauensee (1952a), Mitchell (1954, 1957), Ouellet (1992), de la Peña (1987), Pereyra (1956), Remsen & Hunn (1979), Ridgely & Tudor (1989), Sick (1993), da Silva (1999), Storer (1989b).

270. White-throated Seedeater

Sporophila albogularis

French: Sporophile à gorge blanche **Spanish**: Semillero Gorjiblanco
German: Weißkehlpfäffchen

Taxonomy. *Loxia albogularis* Spix, 1825, Bahia, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Visual similarity to *S. caerulescens* suggests that it may be closest to that species, but molecular-genetic study of present species not yet undertaken. Monotypic.
Distribution. NE Brazil from Piauí E to Pernambuco and S to N Bahia.



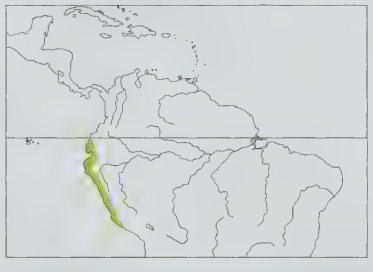
Descriptive notes. 11 cm; 9·7 g. A typically small seedeater, with rather deep-based and thickly rounded bill. Male has crown and face blackish, upperparts dark greyish, upperwing and tail darker, blackish-grey, white flash at bases of primaries; throat and malar region white, white continuing as a half-collar to side of neck below ear-coverts and contrasting strongly with blackish face; distinct and well-defined blackish breastband, rest of underparts whitish, greyish on side of breast, grey wash on flanks; iris dark brown; bill orange-yellow to orange-pink; legs blackish. Distinguished from closely similar *S. caerulescens* by white (not black throat), more greyish (rather than olive-grey) upperparts, and brighter bill colour. Female is nondescript, warm buffy brown on crown, nape and upperparts, wings and tail buff-brown like upperparts; breast a similar warm buff-brown, contrasting whitish throat, darker coloration extending to flanks and contrasting with whitish belly and vent; bill and legs dusky. Juvenile resembles female. Voice. Song a long and persistent quick warble reminiscent of that of a siskin (*Carduelis*); sometimes a mellower, more slowly delivered and more melodious "sweeta sweeta chew-wa tweet-twaa sweeta tweet-cha chuup"; may include mimicry in songs. Call an inflected "chiuuu".
Habitat. *Caatinga* scrub, particularly where near moister sites, and dry woodland borders; 500–1200 m.
Food and Feeding. Diet primarily grass seeds. Forages on ground; sometimes reaches seeds by perching on grass stems. In small groups outside breeding period.
Breeding. Up to four broods per season. Cup-shaped nest of dry grass roots and spider webs, placed low down in shrub. Clutch 2 or 3 eggs, greenish-white with dark spots, some larger and darker, blackish spots near wide end; incubation period c. 13 days. No other information.
Movements. Probably resident. Records from S of range (Minas Gerais and Espírito Santo) thought to refer to escapes from captivity.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in appropriate *caatinga* scrub. Fairly widely kept in captivity.
Bibliography. Armani (1985), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Marcondes-Machado (1982a), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Sick (1993), da Silva (1999).

271. White-bellied Seedeater

Sporophila leucoptera

French: Sporophile à ventre blanc **Spanish**: Semillero Ventriblanco
German: Zweifarbenpfäffchen
Other common names: Black-backed/Bicolored Seedeater (*bicolor*); Grey-backed Seedeater (all other races)

Taxonomy. *Coccothraustes leucoptera* Vieillot, 1817, Paraguay. Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Affinities of this species not clearly understood; recent molecular-genetic analysis indicates close relationship to Bolivian populations of *S. collaris*, but corroboration required. Bolivian race *bicolor* quite different in appearance from others, and may warrant treatment as a separate species. Four subspecies recognized.
Subspecies and Distribution.
S. l. mexianae Hellmayr, 1912 – S Suriname (Sipaliwini) and S Amapá and NE Pará (Mexiana I), at mouth of R Amazon, in Brazil.
S. l. bicolor (d'Orbigny & Lafresnaye, 1837) – extreme SE Peru (Puno) and N & E Bolivia (La Paz, Beni and W & E Santa Cruz).
S. l. leucoptera (Vieillot, 1817) – C & S Brazil (Goiás and Minas Gerais S to Mato Grosso) S through Paraguay to N Argentina (Formosa, Chaco and Santa Fe).
S. l. cinereola (Temminck, 1820) – E Brazil (C Maranhão E to Paraíba, S to Rio de Janeiro).



Descriptive notes. 12–12·5 cm; 15–16 g. A comparatively large seedeater with relatively long tail and deep, very short, rounded bill, giving "pushed-in" look to face. Male nominate race has head dark grey, slightly darker around lores, strongly contrasting white throat and submoustachial area; upperparts similarly greyish, some with narrow white band on rump; upperwing and tail darker grey, white at base of primaries forming small white patch on folded wing (white wingstripe noticeable in flight); entirely white below, slightly more greyish on sides and flanks; iris dark brown; bill bright orange-pink; legs blackish. Female is warm-coloured, tawny-brown above and on wings and tail, tawny-buff below, paler than upperparts but similar in colour tone; throat and belly paler, breast and flanks darker; bill blackish. Juvenile resembles female. Race *cinereola* is smaller than nominate, male paler greyish above, lacks white on rump, has extensive grey on flanks, sometimes a partial grey breastband (as spurs on breast sides), female like nominate but smaller; *mexianae* is similar to previous in being pale grey above, but underparts entirely white, lacking grey on flanks and breast side; *bicolor* is very different, male strikingly black on head and upperparts, female slightly browner above and paler below than nominate. Voice. Song of nominate race a repeated loud, ringing note, "cleeuu cleeuu cleeuu cleeuu cleeuu", sometimes uninflected and similar to songs of a nothura (*Nothura*), at other times single whistles rising in pitch; *bicolor* gives similar repetitive song, also a less monotonous secondary song, "piree pew puu pew puu piree pew puu". In Brazil described as giving characteristic ascending whistle repeated in unhurried manner, "ew-éé, ew-éé, ew-éé...". Call "jayip", like that of House Sparrow (*Passer domesticus*).
Habitat. Shrubby thickets, also secondary-forest edge adjacent to patches of grass; always near water, including lakes and streams, but also marshland. Sea-level to 800 m.
Food and Feeding. Seeds of grasses and other plants appear to be primary food; some insects eaten. In São Paulo (Brazil) young fed with seeds of the exotic grass *Brachiaria*. Often forages while hanging from a stem and extracting seeds. Singly and in pairs; generally not in flocks.
Breeding. Season late Nov/Dec to mid-Feb in E Brazil. Nest cup-shaped, built from thin grass roots and spider silk, thin walls allowing contents to be seen through them, often lined with white cottony seed fluff of "algodão-de-seda" (a milkweed in genus *Calotropis*), gives unique white interior, placed 2·5–4·5 m above ground in shrub or tree, often close to water. Clutch 2 eggs, white, with black and brown spots concentrated at large end; incubation by female alone; chicks fed by both parents; no information on duration of incubation and nestling periods.
Movements. Not well studied. Considered mostly sedentary. In Santa Cruz (Bolivia) not present in all months, suggesting some movement; similarly, in parts of Brazil present only Jan–May. Recorded as a vagrant in SE Peru (Tambopata).
Status and Conservation. Not globally threatened. Tends to be relatively uncommon. Has large range, and believed not to be at immediate risk. Many local populations have been extirpated because of intense commercial trapping and habitat loss, and this species' may require a degree of monitoring. Tolerates some habitat disturbance.
Bibliography. Armani (1985), Buzzetti & Silva (2005), Campagna *et al.* (2010), Dubs (1992), Francisco (2009), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Lougheed (1991), McCarthy (2006), Meyer de Schauensee (1952a), de Oliveira (1981), Ouellet (1992), Renssen (1974), Ridgely & Tudor (1989), Short (1975), Sick (1993), da Silva (1999), Storer (1989b).

272. Parrot-billed Seedeater

Sporophila peruviana

French: Sporophile perroquet **German**: Papageischnabelpfäffchen **Spanish**: Semillero Peruano

Taxonomy. *Callyrhynchus peruvianus* Lesson, 1842, Callao, Peru.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). This species was previously placed in its own genus, *Neorhynchus*, on account of its large and oddly shaped bill, but seems well placed in present genus. Closest relatives not clear. Plumage features similar in some respects to those of *S. caerulescens*; shares some similarities in plumage with *S. simplex*, but is broadly sympatric with it; recent mitochondrial DNA study of genus did not include samples of either of these two. Two subspecies recognized.
Subspecies and Distribution.
S. p. devronis (J. Verreaux, 1852) – W Ecuador (from Manabí) S along coast to NW Peru (Tumbes).
S. p. peruviana (Lesson, 1842) – coast of Peru from La Libertad S to Ica.

Descriptive notes. 10·5–12·5 cm; mean 12·6 g. Largely typical seedeater in its small size, but with massively thick bill showing distinct rounded culmen and slightly hooked tip; bill much thicker and more massive than that of congeners, appearing like that of a parrot (Psittacidae) partly because culmen not evenly rounded, but bends strongly half-way along. Male nominate race has greyish head, narrow white eyering, blackish throat separated from grey of head by white malar area; upperparts greyish-brown, contrasting with strongly grey head; tail grey-brown, central feather pair blackish; upperwing similar to upperparts, upperwing-coverts edged buffy and tipped whitish (forming distinct whitish upper wingbar and more diffuse buffy-white lower one, with slightly buffy panel between the two), primary bases white (forming white patch on folded wing); white band on upper breast bordering blackish throat and intruding into side of neck, below it a dark grey to blackish breastband; underparts otherwise white, flanks with buffy wash; iris dark brown; bill apricot-yellow; legs greyish. Female is very nondescript, lacking obvious patterning, entirely pale dusty brown above, colour not dissimilar to that of female House Sparrow (*Passer domesticus*), lacking contrast with equally dull brown wings and tail; small pale patch visible on folded primaries, and two distinctly paler wingbars present; largely off-white with dusty wash below, chin paler than throat, chest with diffuse pale buffy-brown wash; bill pale horn-coloured, often duskier on upper mandible. Juvenile resembles female. Race *devronis* is fairly similar to nominate, but smaller and with relatively smaller bill. Voice. Male song, from hidden perch, relatively short in duration, nasal and harsh, of only 2–3 notes, "jew-jee-jew" or "jit–jew-tcheew" or "tch-chee!". Call a single nasal note.
Habitat. Arid shrubby areas, hedgerows in agricultural areas or villages, overgrown fields and grassy areas; sometimes along dry watercourses. Sea-level to 800 m.
Food and Feeding. Grass seeds. Forages usually on ground, unlike congeners. Singly, in pairs and in small groups; in larger flocks during non-breeding season, when up to 2000 individuals may gather around watering holes, particularly in dry years. How this species differs in food choice from sympatric, smaller-billed *S. telasco* not studied, but its large size and massive bill suggest that it takes larger and harder seeds; perhaps ground foraging, as opposed to stem foraging, is the major difference.
Breeding. Breeds during Feb–Apr wet season; in wet years may be multiple-brooded. Male sings persistently during breeding season, but difficult to locate. Becomes territorial after first rains, begins breeding 2–4 weeks after first important rains. Nest woven from plant tendrils, and placed in bush, often quite high above ground. Sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Generally sedentary. Seasonal variations in numbers and concentrations suggest that some local movements occur.
Status and Conservation. Not globally threatened. Fairly common to common. Has narrow range, although distribution covers a wide latitudinal span. May benefit from agriculture in desert areas.
Bibliography. Armani (1985), Bond (1951a), Dunning (2008), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Málaga-Arenas & González (2002), Marchant (1958, 1959), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989).

PLATE 66

273. Drab Seedeater

Sporophila simplex

French: Sporophile simple **German**: Dickschnabelpfäffchen **Spanish**: Semillero Simple

Taxonomy. *Spermophila simplex* Taczanowski, 1874, Lima, Peru.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Affiliations uncertain; plumage resembles that of female *S. peruviana*, and conceivable that the two are closely related; molecular-genetic study required. Monotypic.
Distribution. S Ecuador (S Azuay and Loja) and W Peru (upper Marañón Valley and lower Andean slopes from La Libertad S to Ica).

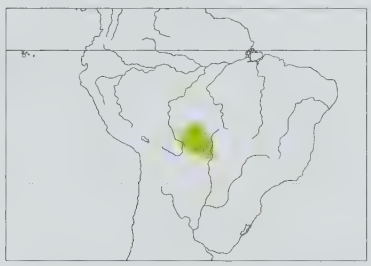
Descriptive notes. 11–11·5 cm. A medium-sized seedeater with rounded bill. Male breeding is greyish-brown above, darker on upperwing and tail; median and greater upperwing-coverts tipped white (forming two narrow whitish wingbars), white bases of primaries (creating white patch on folded wing, wingstripe in flight); whitish below with greyish to buff wash; iris dark brown; bill dull yellow-orange; legs black. Male non-breeding is much like female, but slightly greyer above; this plumage may represent a colour morph, or individual variation, rather than a seasonal change; further investigation required. Female is brownish-buff above, paler below, nearly white on throat and belly; whitish upper wingbar and buffy lower wingbar, and a distinct buffy-white primary patch; bill dusky above, orange-horn on lower mandible; distinguished from rather similar female *S. peruviana* by slightly warmer colour tone of plumage, smaller bill. Juvenile undescribed. Voice. Song a variable rich jumble of warbles and buzzes, similar to that of *S. peruviana* but more notes per phrase. Call a rising "zwee?".
Habitat. Arid scrub, shrubby zones and agricultural sites; 500–2500 m in N of range, down to sea-level in S.
Food and Feeding. Feeds on grass seeds while these still on the stem. Generally in flocks outside presumed wet-season breeding period.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Peru–Chile Pacific Slope EBA. Fairly common. Relatively poorly known species. Habitat appears not to be at any particular risk, and no evidence of any large decline; population likely stable.
Bibliography. Armani (1985), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Schulenberg *et al.* (2007).

274. Chestnut-throated Seedeater

Sporophila telasco

French: Sporophile télasco **German**: Braunkehlpfäffchen **Spanish**: Semillero Gorjicastaño
Other common names: Tumaco Seedeater ("*S. insulata*")

Taxonomy. *Pyrrhula telasco* Lesson, 1828, vicinity of Lima, Peru.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). Taxonomic status of "*S. insulata*" (known only from Tumaco I, off Nariño, in SW Colombia), with rufous rump and underparts, is uncertain: possibly a race of present species, or a mutant population, or a hybrid with *S. minuta*; further study required. Monotypic.
Distribution. Pacific coast and coastal slope from S Colombia (SW Cauca) S through coastal lowlands of Ecuador (inland as far as S Loja) and Peru (where also in upper Marañón Valley) to N Chile (desert valleys of Arica–Parinacota).



Descriptive notes. 10–10·5 cm; two males 8·4 g and 10·9 g. Typical seedeater, tiny and with thick bill approximately as long as it is deep, with distinct rounded culmen. Male has head mid-grey, crown feathers with deep chestnut bases (which become more noticeable as plumage wears), upperparts greyish, slightly browner on hindneck and lower back, with crown to mantle distinctly streaked dusky (unusual in genus); rump white, uppertail-coverts grey; upperwing blackish, greyish fringes on coverts (on some forming indistinct greyish wingbars) and tertials, noticeable white patch at base of primaries; tail feathers blackish with greyish edging, extreme bases of rectrices white (sometimes visible in the field); throat to upper breast dark chestnut, tiny white patches at base of malar tract; otherwise, entirely whitish below; iris dark brown; bill and legs black. Female in fresh plumage is warm brown above, noticeably streaked darker on crown, nape and mantle, wings more blackish, warm brown fringes on coverts and tertials and noticeable white primary patch, tail similarly blackish with warm brown fringes; white on throat, buffy breastband continuing to flanks, and whitish from lower breast to undertail-coverts; in worn plumage more greyish-brown, not so warm-toned; bill dull pinkish, legs dusky. Immature male is variable, intermediate in plumage between adult male and adult female, often resembles female but with greyish wash on upperparts and some chestnut on throat. Voice. Song a short and staccato musical warble, sometimes with sputter towards end, quality sharp and rich, each note having great frequency range and with bouncing cadence, although songs variable, "chwiip chipiti chaw-pwee" or "chwit cheepa chupa-chit-chupawhit". Call a fine "zeeteep" and a "cheep".
Habitat. Shrubby and open areas, including edge of dry grassland, agricultural areas, desert oasis valleys, hedgerows and edges of small towns and villages; sea-level to 1000 m.
Food and Feeding. Diet largely of grass seeds; feeds nestlings with grass seeds. Forages both on ground and, more usually, while perched on grass stalks or other stems as it extracts seeds. Often in large flocks outside breeding period.
Breeding. Breeds in Feb–May rainy season in Ecuador and Peru (in SW Ecuador 2–5 weeks later than sympatric *S. peruviana*); farther S, where no rainy season, may breed also in that period, but confirmation required. Nest a cup woven from dry grasses and stems, built close to ground in low-growing annual plant or low shrub. Some nests parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Resident; possibly some short local movements.
Status and Conservation. Not globally threatened. Common to abundant throughout its range. Has a large range from N to S. Agriculture in desert areas is likely increasing the amount of suitable habitat for this species.
Bibliography. Armani (1985), Butchart & Stattersfield (2004), Jaramillo (2003), Klicka *et al.* (2007), Marchant (1958, 1959, 1960), McCarthy (2006), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Sabel (1981), Stattersfield & Capper (2000), Stiles (2004).

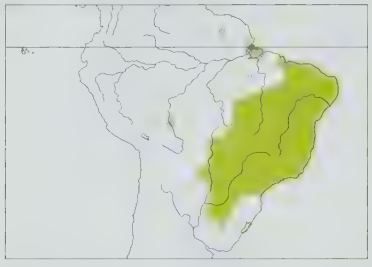
275. Black-and-tawny Seedeater

Sporophila nigrorufa

French: Sporophile noir et roux **Spanish**: Semillero Rojinegro
German: Schwarzmantelpfäffchen

Taxonomy. *Pyrrhula nigro-rufa* d'Orbigny and Lafresnaye, 1837, Chiquitos, Bolivia.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). This species presumed most closely related to *S. bouvreuil*, and part of the S clade of "capped" seedeaters (*S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris*, *S. cinnamomea*, *S. melanogaster*). Monotypic.
Distribution. E Bolivia (E Santa Cruz; recently also Llanos de Moxos, in NE Beni) and SW Brazil (W Mato Grosso).

Descriptive notes. 10 cm. A typically shaped seedeater, small in size, and with thick, stout but short bill with rounded culmen. Male has well set-off black cap reaching to just below level of eye, cheek and ear-coverts tawny-cinnamon, narrow black band on nape joining with black of upperparts, including upperwing and tail, dark tawny on lower back and rump; primaries with white at bases (very small white patch on folded wing often entirely hidden on perched bird, but evident as whitish wingstripe in flight); in fresh plumage, tertials broadly fringed white, greater upperwing-coverts crisply fringed white (creating pale panel on closed wing); cinnamon-tawny from chin to undertail-coverts, this colour also intruding to side of neck; iris dark brown; bill blackish, in non-breeding period pinkish-horn with dark culmen; legs black. Female is typically dull, sandy with olive tone on head and upperparts, upperwing and tail rather uniform dusky olive with paler edging; pale yellowish on throat, slightly tinged olive on breast, off-white to pale cinnamon on rest of underparts; bill horn-coloured, legs dusky. Younger immature male is similar to adult female, but with greenish feather tips on crown and upperparts; older immature male similar to adult male, but cap brownish, upperpart feathers tipped green, wing-coverts and tertials lack bold white fringes, underparts paler. Voice. Song a pleasant series of whistles, more resonating than songs of most other members of clade and notes delivered at slow and leisurely pace, "cheeooo cheeooo, tp-twee, tp-cheeo, tp-twee, tpweeo, tp-twee, chp-weeo, tp-twee ...". Calls include nasal "phhht", sharper "puut" and rising "cheeé".
Habitat. Grassy *cerrado* habitats, also tall-grass areas near water, open savanna; sea-level to 500 m.
Food and Feeding. Little information. Feeds on grass seeds. Forages while clinging to grass stem at heights of 0·5–1·5 m above ground, extracting seeds from seedheads. In flocks of up to 100 or more, mainly in presumed non-breeding season.
Breeding. No information.
Movements. Appears to be migratory. Exhibits classic austral migration pattern: present E Bolivia (Noel Kempff Mercado National Park) during presumed breeding season of Oct–Dec, peak in May (possibly migration), and largely absent Jul–Oct.
Status and Conservation. VULNERABLE. Rare and local. A very poorly known species. After initial description, in 1830s, this species disappeared until 1979, when rediscovered in Brazil. Currently known from eight locations in Bolivia and three in adjacent Brazil. Has small population, which likely to be in continuous and rapid decline owing to habitat loss and degradation caused by conversion of grassland to agriculture. Main breeding site Flor de Oro, in Noel Kempff Mercado National Park (Santa Cruz); local density of 2 birds/km² estimated at Los Fierros, in Neol Kempff Mercado. In Brazil, 55 presumably breeding individuals counted E of Vila Bela da Santaissima Trinidade (Mato Grosso) in Jan 1988, and at least 100 (non-breeding condition) present there in Jul 1997. In Bolivia, occurs at three sites in Noel Kempff Mercado National Park, also in Otuquis National Park; present in Pantanal Matogrossense National Park, in Brazil. Noel Kempff Mercado was extended to W in 1997, and now protects more habitat suitable for this species.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Campagna *et al.* (2010), Güller (2008), Hennessey *et al.* (2003), Herrera & Maillard (2007), Kirwan & Areta (2009), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Sick (1993), Stattersfield & Capper (2000).



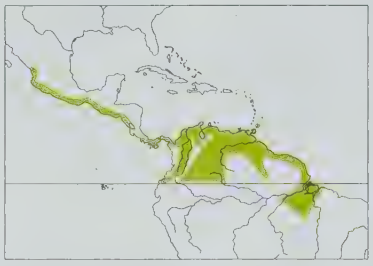
276. Capped Seedeater

Sporophila bouvreuil

French: Sporophile bouvreuil **German**: Orangepfäffchen **Spanish**: Semillero Capinegro
Other common names: Sao Paulo Seedeater (*saturata*)

On following pages: 277. Ruddy-breasted Seedeater (*Sporophila minuta*); 278. Tawny-bellied Seedeater (*Sporophila hypoxantha*); 279. Rufous-rumped Seedeater (*Sporophila hypochroma*); 280. Dark-throated Seedeater (*Sporophila ruficollis*); 281. Marsh Seedeater (*Sporophila palustris*); 282. Chestnut-bellied Seedeater (*Sporophila castaneiventris*); 283. Chestnut Seedeater (*Sporophila cinnamomea*); 284. Black-bellied Seedeater (*Sporophila melanogaster*).

Taxonomy. *Loxia bouvreuil* Statius Müller, 1776, Bahia, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. castaneiventris* and *S. minuta*, and a S clade consisting of present species and *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*; relationships within S clade not possible to determine, as genetic differentiation very low and species apparently part of a very recent and rapid radiation, only present species appearing genetically more distinct within clade. It has recently been suggested that pale race *pileata* may merit treatment as a separate species; also, that *saturata* and *crypta* be synonymized with nominate; further research needed. Four subspecies recognized.
Subspecies and Distribution.
S. b. bouvreuil (Statius Müller, 1776) – S Suriname; E Brazil at mouth of R Amazon and from Maranhão E to Rio Grande do Norte, S to Goiás, NE São Paulo and Rio de Janeiro.
S. b. pileata (P. L. Sclater, 1865) – C & S Brazil (locally in E Pará, and from S Mato Grosso and S Minas Gerais) S through E Paraguay to NE Argentina (Corrientes and Misiones), locally to N Uruguay; also locally in NE Bolivia (Beni).
S. b. saturata Hellmayr, 1904 – environs of city of São Paulo, in SE Brazil.
S. b. crypta Sick, 1968 – environs of city of Rio de Janeiro, in SE Brazil.

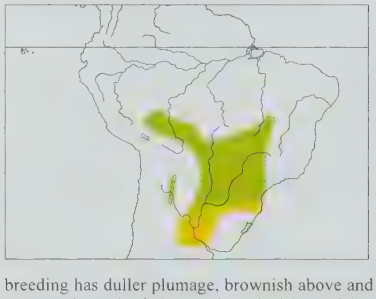


Descriptive notes. 10 cm; 7·6–10 g. Typical seedeater, tiny and with thick bill approximately as long as it is deep, with distinctly rounded culmen. Male nominate race has clean-cut black cap reaching down to level of eye, contrasting cinnamon face and nape, with similar cinnamon colour on throat and entire underparts, except for black thigh; cinnamon of nape continues down back to uppertail-coverts; tail and upperwing contrastingly blackish, wing-coverts and tertials fringed cinnamon-brown (creating cinnamon wing-panel, in fresh plumage), noticeable white at base of primaries (forming rectangular white patch on folded wing); iris dark brown; bill and legs blackish. Female is dull olive-brown above and ochre-buff below, becoming whitish on belly; bare parts as for male. Juvenile resembles female. Races differ in plumage of males: *pileata* is paler than nominate, especially below, where off-white, creamy or pinkish (marked variation in strength of underpart coloration), and paler birds often have more greyish-brown back, also male has non-breeding plumage resembling that of female (but with larger white wing patch, yellowish bill), first-year male paler still, almost whitish below; *saturata* is darker than nominate, chestnut (rather than cinnamon) below; *crypta* is unusual in that breeding male is essentially female-like in plumage, a few showing black specks on crown. Voice. Classic song a series of sweet whistles that fall in pitch, "twee tweeta cheew tweeta phwee", phrases containing pleasant and nicely resonating whistles; another song type described as long, hurried, with varied notes, and tempo of siskin (*Carduelis*); may incorporate mimicry in song. Call a strident "tslit" or a two-note "ewt-eet".
Habitat. Open *cerrado* in N of range, savannas and tall-grass (old) grasslands in S; sea-level to 1100 m.
Food and Feeding. Diet of grass seeds. Forages usually by clinging to grass stem and extracting seeds. Generally in pairs during breeding season, but sometimes joins with other members of genus; may forage in small flocks during non-breeding season.
Breeding. No information.
Movements. Resident in most of range. Migratory in S part of range; many or most of those in Argentina, Uruguay and extreme S Brazil retreat N from late Feb, returning in Nov. Abundance in a given area increases when grass in seed.
Status and Conservation. Not globally threatened. Common to abundant in N part of range; uncommon in S. Has large range and is relatively numerous. Much of this species' habitat is being burnt, being converted to the growing of soybean or sunflowers, or being overgrazed, and populations therefore likely to be declining.
Bibliography. Armani (1985), Belton (1985), Campagna *et al.* (2010), Dunning (2008), Herrera & Vidoz (2009), Klicka *et al.* (2007), Machado & Silveira (2011), McCarthy (2006), Mees (1968), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Sick (1968, 1993).

277. **Ruddy-breasted Seedeater**
Sporophila minuta

French: Sporophile petit-louis **German**: Zwergpfäffchen **Spanish**: Semillero Pechirrufo
Other common names: Minute/Pygmy Seedeater

Taxonomy. *Loxia minuta* Linnaeus, 1758, Suriname.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). This species was at one time considered conspecific with *S. hypoxantha*, but molecular data and vocal details suggest that the two are not very closely related. A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing present species and *S. castaneiventris*, and a S clade consisting of *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*. Three subspecies recognized.
Subspecies and Distribution.
S. m. parva (Lawrence, 1883) – arid Pacific lowlands from W Mexico (Nayarit) S to Nicaragua.
S. m. centralis Bangs & T. E. Penard, 1918 – SW Costa Rica and Pacific slope of Panama.
S. m. minuta (Linnaeus, 1758) – N Colombia S to NW Ecuador, E to Venezuela, Trinidad, Tobago, the Guianas, and N Brazil (NW Amazonas, N Roraima, and Amapá S to N Pará).
Descriptive notes. 8·6–9·6 cm; 7–9 g. A tiny seedeater. Male nominate race has crown and face mid-grey, this colour continuing to back, which is diffusely streaked brownish; lower back and rump rufous, longest uppertail-coverts grey like back; upperwing blackish-brown, wide grey fringes on coverts and tertials, white at bases of primaries (forming distinct white rectangular patch on folded wing); tail feathers blackish with olive fringes; white spot at base of lower mandible, grey of ear-coverts cleanly separated from rufous of submoustachial region and throat, entire underparts rufous; iris dark brown; bill and legs blackish. Female is nondescript, warm buffy brown on crown, nape, mantle and back; wings and tail buff-brown like upperparts (in fresh plumage may show narrow cinnamon-brown wingbars); breast a similar warm buff-brown, contrasting with paler throat,



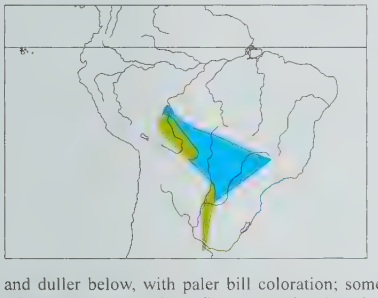
darker coloration extending to flanks and contrasting with paler buff belly and vent; crissum darker than belly, similar to flanks; bill dark horn-coloured. Juvenile is like female; young male gradually acquires rufous on underparts and greyish on upperparts. Race *parva* male is more blue-grey above than nominate, lacking brownish tones, female warmer buff below than other races; *centralis* is smaller than nominate, male with more of a brownish wash on upperparts, paler underparts, female similar to nominate. Voice. Song simple, but sweet and plaintive, "see-seeur tee-te-e-e-e, seeeeur tse-e-e-e-e", in some places with trill reduced to a few notes, or a fairly long, sweet "weet, weet, too eet tew". Call a sharp "chip" or "chink" (varies geographically).
Habitat. Open spaces, often on roadsides, in parks and near dwellings; in bramble (*Rubus*) and wild rose (*Rosa*) thickets, old clearings with bracken (*Pteridium*) and pines (*Pinus*). Found in open savannas, sometimes on farms or in gardens. Sea-level to 2200 m.
Food and Feeding. Overall, a specialist on grass seeds; in Venezuela may feed on soft unripe seeds of *Digitaria* grasses. May vary diet with some other types of seed, fruit, and arthropods, depending on season and availability. Forages principally by perching on grass seedheads, bending down the grass with its own weight while extracting seeds as it clings to stem, often with head down as it does so. Often in groups with other seedeaters.
Breeding. Season Jun–Aug in Central America; mainly Apr–Sept in Colombia. Monogamous. Nest a simple but coarse open cup of grasses, stiff grasses projecting from rim, placed low in grass or in low bush or small tree. Clutch 2–3 eggs, white with brown or reddish-brown spotting. No other information.
Movements. Mostly sedentary. If grass-seed stock low, as in a period of drought or during a long dry season, this species moves elsewhere; dynamics of these erratic movements not known.
Status and Conservation. Not globally threatened. Often common or abundant in appropriate habitat in much of range; rarer and more local in Ecuador.
Bibliography. Anon. (1998), Armani (1985), Dunning (2008), Hellmayr (1938), Hilty & Brown (1986), Howell & Webb (1995), McCarthy (2006), Meyer de Schauensee (1952a), Miller *et al.* (1957), Ouellet (1992), Restall *et al.* (2006), Ridgely & Tudor (1989), Ridgway (1901), Stiles & Skutch (1989), Weathers (1997), Wetmore *et al.* (1984).

278. **Tawny-bellied Seedeater**
Sporophila hypoxantha

French: Sporophile à ventre fauve **Spanish**: Semillero Ventricanela
German: Ockerbrustpfäffchen

Taxonomy. *Sporophila hypoxantha* Cabanis, 1851, Montevideo, Uruguay.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). This species was at one time considered conspecific with *S. minuta*, but molecular data and vocal details suggest that the two are not very closely related. A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypochroma*, *S. ruficollis*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Monotypic.
Distribution. N, W & E Bolivia (La Paz, E Beni and Santa Cruz), Paraguay, Brazil S of Amazon Basin (S Mato Grosso, Goiás and W Minas Gerais S to N Rio Grande do Sul), NW & NE Argentina (Salta S to N Tucumán and N Cordoba; Formosa and Misiones S to Santa Fe, Corrientes and Entre Ríos), and marginally W Uruguay.

Descriptive notes. 10 cm; 10·5 g. A classic seedeater, tiny and with rounded culmen. Male breeding has crown to mantle and upper back greyish (sometimes sandy tips of back feathers when plumage fresh), lower back and rump tawny; tail contrastingly blackish, edges of outer rectrices grey (giving grey-based appearance to folded tail, as edges wider basally); upperwing dark greyish, edged sandy brown (creating brownish wingpanel), white at primary bases (most evident in flight); lower side of head to throat and entire underparts tawny to pale rufous, often darkest on belly; iris dark brown; bill and legs black. Male non-breeding has duller plumage, brownish above and duller on underparts, with paler bill coloration; some males paler below and washed brownish on wings and tail, these likely first-year males. Newly described morph ("*uruguaya*") has tawny of rump extending right up onto nape, isolating grey cap; thus, very similar to *S. cinnamomea*, but paler. Female is relatively warm-coloured, sandy brown above, often with paler buff forehead and supercilium, warm buff below, palest on middle of throat and belly; wings and tail darker, two dull sandy wingbars (when plumage fresh), also a small whitish primary patch; bill and legs dark horn to blackish. Juvenile resembles female; younger male much like female, but may have dark speckling on crown or back. Voice. Song simple and sweet, comprising clear descending whistles, can sound rather monotonous, "cheeu cheeu chewee chu", the whistles given at longer intervals than in songs of other members of clade and more mellow-sounding, song somewhat reminiscent of that of Eastern Meadowlark (*Sturnella magna*); in SE Brazil notes shorter and more staccato, making song sound more choppy. Recent work reveals significant geographical variation in song, with five discernible types from: lowland Bolivia; Formosa; Entre Ríos; Corrientes; and SE Brazil. Common call a mellow, descending "pheeooo"; also gives thin "tsi" or "tsit".
Habitat. Tall moist grasslands, rolling grassy hillsides, also roadside patches of grassland that have been allowed to grow to an older stage; often near marshes or a moist spot adjacent to grassland. In N Argentina (Formosa) breeds in dry grasslands of *Elionurus muticus* and *Imperata brasiliensis* or *Andropogon lateralis*, and in wet grasslands of *Paspalum intermedium* and *Sorghastrum setosum*. Sea-level to 1100 m.
Food and Feeding. Grass seeds. Often perches on stems, and feeds on grass seeds while clinging to stem. Forages in small groups; also in mixed flocks with other seedeaters.



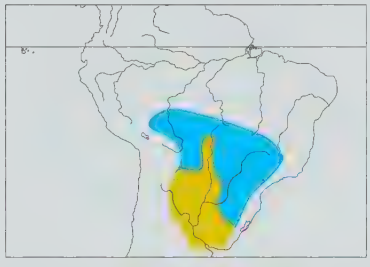
Breeding. Season mainly Oct/Nov–Feb, locally to Apr; in SE Brazil (Santa Catarina) peak in late Nov, and in N Argentina (Formosa) laying starts in second half Oct and continues until second half Mar. Nest, built solely by female, a well-concealed cup of dry grasses, placed close to ground (usually below 45 cm, but to 1 m up) and attached to taller weed stalk or shrub (often of family Asteraceae) in denser section of grass; in Brazil, *Eupatorium polystachyum* and *Vernonia chamaedrys* account for nearly half of all plants used for nesting. Clutch 2–3 eggs, cream-coloured with brown and blackish markings spread throughout; incubation by female, period 11–12 days; chicks initially fed only by female, after 5 days male assists in foraging to collect food for chicks, nestling period c. 9–10 days.
Movements. S populations migratory, retreating N after breeding season; arrival in breeding areas in Nov–Dec, departure by Feb–Mar. Some N Argentine populations may be partially resident, e.g. in Formosa and Entre Ríos, whereas those in S Brazil all migratory; wintering grounds not clearly known, but appear to be in *cerrado* of C Brazil.
Status and Conservation. Not globally threatened. Fairly common; rare, possibly extinct, in Uruguay. Has large breeding range. The old/tall grasslands required by this species are becoming less common throughout its range owing to conversion to commercial crops such as soya and sunflower, overgrazing and, in some areas, frequent burning.
Bibliography. Areta & Repenning (2011a, 2011b), Armani (1985), Belton (1985), Benites *et al.* (2010), Campagna *et al.* (2010), Canevari *et al.* (1991), Claramunt *et al.* (2006), Facchinetti *et al.* (2008), Fontana *et al.* (2010), Franz & Fontana (2010), Kirwan & Areta (2009), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Lopes *et al.* (2010), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Short (1969, 1975), Sick (1993).

279. **Rufous-rumped Seedeater**

Sporophila hypochroma

French: Sporophile à croupion roux **German**: Rotbürzelpfäffchen **Spanish**: Semillero Culirrufo
Other common names: Grey-and-chestnut/Rufous-naped Seedeater

Taxonomy. *Sporophila hypochroma* Todd, 1915, Buena Vista, Santa Cruz, Bolivia.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypoxantha*, *S. ruficollis*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Monotypic.
Distribution. Locally in N & E Bolivia (Beni, La Paz and W Santa Cruz), SW Brazil (S Mato Grosso and S Goiás), C Paraguay, NE Argentina (E Formosa and E Chaco S to Corrientes, Entre Ríos and N Buenos Aires) and W Uruguay.



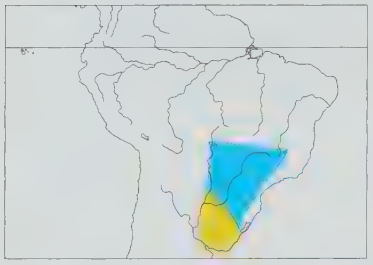
Descriptive notes. 10 cm; one young male 9·7 g. A tiny seedeater with small, rounded bill. Male breeding has crown to mantle and upper back greyish, lower back and rump chestnut; tail contrastingly blackish, edges of outer rectrices grey (giving grey-based look to folded tail, as these edges wider basally); upperwing blackish, white on primary bases (most obvious in flight), tertials black with grey edging; lower side of head to throat and entire underparts chestnut; iris dark brown; bill and legs black. Differs from very similar *S. hypoxantha* in having colours more saturated. Male non-breeding has duller plumage, brownish above and duller below, with paler bill coloration; some males paler below and washed brownish on wings and tail, these likely first-year males. Female is relatively warm-coloured, being sandy brown above, often with paler buff forehead and supercilium, warm buff below, palest on middle of throat and belly; wings and tail darker, two dull sandy wingbars when plumage fresh; bill dark horn to blackish, legs dusky. Juvenile resembles female; younger male much like female, but may show dark speckling on back or crown. Voice. Song more complex than that of other "capuchino" seedeaters, a long warble with many inflected ascending or descending nasal whistles, but also has a cadence reminiscent of slowed-down song of a siskin (*Carduelis*). Call a rising "pwee".
Habitat. Tall grasslands adjacent to marshes or other open wetlands; breeding evidently confined to seasonally wet low-lying grasslands. To 1100 m.
Food and Feeding. Grass seeds. Clings to grass stem while foraging for seeds. Sometimes in mixed flocks with other members of genus.
Breeding. Season Dec–Feb. No other information.
Movements. Poorly known. Partially migratory, but details of movements and precise location of non-breeding grounds incompletely known.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally uncommon to rare, and very patchily distributed. Range sometimes mapped as rather large, but appears to be comprised of two disjunct populations, one in E Bolivia and the other in NE Argentina. Population may be in rapid decline owing to loss of native grasslands, as well as trapping for the cagebird trade. Much native grassland within this species' range has been replaced by exotic pine (*Pinus*) and/or eucalypt (*Eucalyptus*) plantations, grown for pulp wood. Protection of important native grasslands is considered necessary for this and many other Neotropical species.
Bibliography. Anon. (2010c), Benites *et al.* (2010), Butchart & Stattersfield (2004), Campagna *et al.* (2010), Claramunt *et al.* (2006), Kirwan & Areta (2009), Klicka *et al.* (2007), McCarthy (2006), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Roda & López-Lanús (2008), Short (1969), Stattersfield & Capper (2000).

280. **Dark-throated Seedeater**

Sporophila ruficollis

French: Sporophile à gorge sombre **Spanish**: Semillero Gorjioscuro
German: Schwarzkehlpfäffchen

Taxonomy. *Sporophila ruficollis* Cabanis, 1851, Montevideo, Uruguay.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Has been suggested that present species is a colour morph of *S. hypoxantha*. Monotypic.
Distribution. N & E Bolivia (E La Paz, Beni, E Santa Cruz and E Tarija), S Brazil (S Mato Grosso, S Goiás, W Minas Gerais, W São Paulo and Rio Grande do Sul), W & C Paraguay, N Argentina (Salta E to Corrientes, S to Tucuman, N Cordoba and N Buenos Aires) and N & W Uruguay.



Descriptive notes. 10–11 cm; 7–9·7 g. A distinctive small seedeater, small-billed and relatively long-tailed. Male breeding has forehead to nape and hindneck grey, this colour extending down below eye to upper cheek (creating helmeted appearance, rather than capped pattern); mantle and upper back also grey, sometimes browner than crown, lower back and rump rufous or dark cinnamon; tail contrastingly blackish, some grey edging on outer rectrices; upperwing blackish, coverts narrowly edged grey-brown, tertials more widely edged grey-brown, a noticeable white patch at base of primaries; ear-coverts and cheek to throat and upper breast distinctively blackish-brown, rest of underparts rufous; a recently described morph has brown of throat extending to hindneck, entirely rufous upperparts; iris dark brown; bill and legs dark grey to black. Male non-breeding has duller plumage, with mix of grey and brown on upperparts, paler throat and underparts, and yellowish base of lower mandible. Female is relatively warm-coloured, warm brown above, face uniformly buff, dark eye showing up prominently; wings and tail darker, two dull sandy wingbars when plumage fresh; warm buff below, palest on belly; bill dark horn to blackish, legs blackish. Juvenile is like female; young male in later stages darker on upperparts and buffier on underparts, dark feathers finally appearing on upperparts and throat; some long-standing territorial males observed to retain an immature plumage for years, suggesting that some may never (or only when very old) acquire full adult plumage. Voice. Song sweet and mellow, a series of descending whistles, sometimes with a more complex series of notes towards end, usually begins with two or three whistles, "pheeeh weeo pweeo" or "phee phee feeo pt-pheeo phwit". Calls include quiet "tsiew", "jep" or "tsilew" notes.
Habitat. Old tall grasslands, sometimes near a moist grassy swale, but not so dependent on adjacent marshland as are other "capuchinos"; also roadside grassy areas if grass allowed to grow high. Also in scrubbier habitats, not necessarily near water, in NE Argentina. In non-breeding period also in grassy *cerrado* habitat. Sea-level to 1200 m.
Food and Feeding. Grass seeds. Forages while clinging to grass stems and eating the seeds. Often in small groups or mixed-species flocks.
Breeding. Season Dec–Feb. Nest a cup-shaped structure of dry woven vegetation, fortified with spider webs, mean diameter 4·5 cm, depth 4 cm, placed c. 0·5 m from ground in low vegetation. Clutch 2–3 eggs, whitish with ochre, grey and black markings distributed throughout, but concentrated at wide end. No other information.
Movements. Migratory. Arrives in breeding range in late Nov to Dec; good numbers of this species spend winter months in Cerrado region of Mato Grosso, in S Brazil. Found relatively commonly on passage in NE Paraguay.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally uncommon to rare; fairly common to common in N Bolivia. Has relatively large distribution. Considered to be undergoing a moderately rapid population decline. Has clearly decreased in NE Argentina. As with many grassland-dwelling seedeaters, this species is commonly trapped for the cagebird trade and its habitat has been extensively converted to agriculture, with unsuitable crops such as soya and sunflower, and also to plantations of exotic eucalypts (*Eucalyptus*) and pines (*Pinus*); also suffers from overgrazing of grasslands, annual burning on adjacent agricultural land, and pesticide usage. Protection of native grasslands required in order to ensure this species' future survival.
Bibliography. Anon. (2010c), Areta (2009a), Areta *et al.* (2011), Armani (1985), Belton (1985), Benites *et al.* (2010), Butchart & Stattersfield (2004), Campagna *et al.* (2010), Canevari *et al.* (1991), Di Giacomo, A.S. *et al.* (2010), Kirwan & Areta (2009), Klicka *et al.* (2007), Meyer de Schauensee (1952a), Ouellet (1992), de la Peña (1987), Ridgely & Tudor (1989), Short (1969), Sick (1993), Stattersfield & Capper (2000).

281. **Marsh Seedeater**

Sporophila palustris

French: Sporophile des marais **German**: Sumpfpfäffchen **Spanish**: Semillero Palustre
Other common names: White-bibbed Seedeater; Narosky's/Entre Rios Seedeater ("*S. zelichi*")

Taxonomy. *Spermophila palustris* Barrows, 1883, near Concepción del Uruguay, Entre Ríos, Argentina.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. cinnamomea* and *S. melanogaster*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Has been suggested that present species is a white-throated morph of *S. ruficollis* or a colour morph of *S. hypoxantha*. In addition, form described as *S. zelichi* (from Entre Ríos, in NE Argentina) considered to be a white-necked morph of present species, to which it is vocally identical, and found in same habitat and at same locations as it; or possibly a hybrid between present species and *S. cinnamomea*. Monotypic.
Distribution. Breeds in NE Argentina (Corrientes and Entre Ríos, possibly also Buenos Aires), extreme SE Brazil (Rio Grande do Sul) and Uruguay (R Uruguay basin and SE wetlands), possibly also SE Paraguay. Migrates N as far as SC Brazil (N to S Mato Grosso, S Goiás and W Minas Gerais) and E Paraguay.
Descriptive notes. 10 cm; 7·5–9 g. Typical "capuchino" seedeater, very small in size, small-billed and relatively long-tailed. Male has grey forehead and lores to nape, similarly grey mantle and back, rufous lower back and rump; tail contrastingly blackish, some grey edging on outer rectrices; upperwing blackish, narrowly grey-edged coverts, more widely grey-edged tertials, a noticeable white patch at base of primaries; distinctive snow-white on throat and face reaching up to eye level

and extending down to upper breast; rest of underparts rufous; iris dark brown; bill and legs black. At least some males moult into a brown plumage after breeding (how widespread this is requires more research). Female is relatively warm-coloured, warm sandy brown above, face uniformly buff, dark eye showing up prominently; wings and tail darker, coverts with sandy-brown edging that on some appears as two dull sandy wingbars when plumage fresh; warm buff below, whitish on belly and sometimes on middle of throat and breast; bill dark horn to blackish, legs blackish. Juvenile is very like female; young male in later stages darker on upperparts, buffier on underparts, eventually dark feathers begin to show on upperparts and white ones on throat. Voice. Song sweet, melodious and pleasant, composed largely of sweet descending whistles, and with distinctive note that rises in pitch before falling, "tweeew tri tweew teee tweéé0000 twip tweew tweew teee tweéé000 twip..."; overall a tad higher-pitched than song of closely related *S. cinnamomea*, and with characteristic rising and falling note. Songs appear to alter over time, with slight but detectable changes between songs from 1980s and those in 2000s. Rarely, some males territorial and sing while still in immature plumage. Call typically a sweet descending whistle, "twéeeeeww", also "tslit".

Habitat. For breeding requires older, taller very moist grasslands or grass adjacent to marshes. Of the "capuchino" seedeaters perhaps the one most closely tied to marshes; often perches on a taller stalk (such as *Erigonum*) in otherwise straight *Scirpus* or *Typha* marshes. In non-breeding range also in dry grassland. Sea-level to 1100 m.

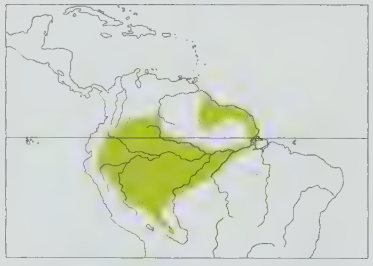
Food and Feeding. Grass seeds. Forages while clinging to grass stems. Often in mixed flocks with other seedeaters.

Breeding. Season Dec–Feb. No other information.

Movements. Migratory; apparently breeds only in S part of range during austral spring and summer, and then migrates N. Details of movements remain to be determined.

Status and Conservation. ENDANGERED. Relatively rare and locally distributed. Estimated global population in range 1000–2499 mature individuals. Has fairly small breeding range and very small population. Has suffered extensive habitat loss and degradation; moist or flooded grasslands are often drained or overgrazed. In addition, this species suffers from widespread trapping for the cagebird trade, as its unique coloration is favoured by bird-collectors. A main threat is the replacement of native grassland and other vegetation with exotic pine (*Pinus*) and eucalypt (*Eucalyptus*) plantations; this not only eliminates suitable grassland habitats, but also decreases chances of migrating birds of locating their naturally variable and spatially scattered food resources. Similarly, some seasonally inundated grasslands and marshes, e.g. in S Paraguay and parts of Uruguay, have been converted to rice fields. Further threats include annual burning of grasslands, which destroy or put at risk migration stopover sites and non-breeding habitats, and use of pesticides in foraging areas. Legally protected in Brazil, Paraguay and Uruguay; trapping of this species prohibited in Argentina and Uruguay, but enforcement of laws not fully effective. Breeds in several protected areas, including Iberá Provincial Reserve (Argentina) and Potrerillo de Santa Teresa Reserve (Uruguay); in Brazil, Das Emas National Park possibly an important wintering site, and has been recorded also in Espinilho Ecological Park, Ibirapuitã and São Donato Biological Reserves and Itirapina Ecological Station; occurs in two protected areas within San Rafael National Park (Paraguay), where a monitoring scheme is studying threatened grassland birds. Passage migrants occur in several Paraguayan and Argentine reserves. Surveys needed in order to ascertain this species' precise breeding and non-breeding ranges, and effective enforcement of laws required.

Bibliography. Anon. (2010c), Areta (2008, 2009a), Armani (1985), Azpiroz (2003b), Butchart & Stattersfield (2004), Campagna *et al.* (2010), Di Giacomo, A.S. *et al.* (2010), Hirschfeld (2007), Klicka *et al.* (2007), Lopes *et al.* (2010), Meyer de Schauensee (1952a), Ouellet (1992), Ridgely & Tudor (1989), Sick (1993), Stattersfield & Capper (2000).



282. Chestnut-bellied Seedeater

Sporophila castaneiventris

French: Sporophile à ventre châtain **Spanish**: Semillero Ventricastaño
German: Rotbauchpfäffchen

Taxonomy. *Sporophila castaneiventris* Cabanis, 1848, Cumaka, coast of Guyana.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing present species and *S. minuta*, and a S clade consisting of *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris*, *S. cinnamomea* and *S. melanogaster*. Proposed taxon *S. hypochroma rothi* (based on single specimen from near Abary, in NE Guyana) likely a hybrid between present species and *S. minuta*. Monotypic.

Distribution. The Guianas, and E Colombia (from Guainía and Meta) and S Venezuela (extreme SW Amazonas) S, E of Andes, to Ecuador, Peru and N & W Bolivia (Pando, La Paz, Beni and Cochabamba), and Amazonian Brazil (S to NW Mato Grosso and N Pará, also NE Roraima and Amapá).

Descriptive notes. 10 cm; average 7·8 g. Typical seedeater, very small in size, and with stubby, rounded bill. Male has entire head down to cheek and ear-coverts blue-grey, this colour continuing on upperparts to back and rump; tail blackish, grey edging at base of outer rectrices; upperwing blackish, feathers edged greyish, particularly on tertials, sometimes a hint of paleness on primary bases; sometimes a tiny white spot at base of lower mandible, rest of submoustachial region and throat chestnut, this colour broadening at breast, then narrowing but continuing down mid-line of underparts on belly, broadening again on vent and undertail-coverts; flanks blue-grey, similar in colour to upperparts; iris dark brown; bill and legs black. Female is relatively warm-coloured, warm sandy brown above, face uniformly buff, dark eye showing prominently; upperwing and tail darker, wing-coverts with sandy-brown edging (can give impression of two dull sandy wingbars when plumage fresh); warm buff below, palest on belly and sometimes on middle of throat and breast; bill dark horn to blackish, legs blackish. Juvenile is very like female, male with more distinctive buffy edging on wing feathers; male becomes progressively more like adult, first acquiring a patchy plumage mixing browns with grey and chestnut feathering. Voice. Song a quick warble of nasal whistles; sometimes gives a longer and more complex song with many rambling notes and repeated phrases. Call a descending "cheeoo" whistle or a shorter "tsiep".

Habitat. Grassy and shrubby clearings, agricultural areas, and lawns and grassy openings in towns and villages; also floating vegetation in lakes or *cochas* (artificial lagoons). Recorded from sea-level up to 500 m.

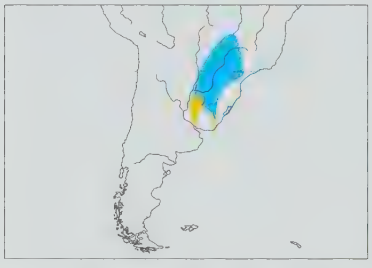
Food and Feeding. Grass seeds; also fruits of *Cecropia* trees, as well as their Müllerian bodies. Forages on grasses while on the stem; also on ground when prostrate stems of grasses available. When eating fruit, takes those already opened by larger species. Often in groups or small flocks.

Breeding. No information available.

Movements. Insufficient information. Possibly a partial migrant.

Status and Conservation. Not globally threatened. Common and widespread. In some areas this seedeater appears to be expanding its range.

Bibliography. Armani (1985), Beebe (1917), Benites *et al.* (2010), Borges & Torres de Macedo (2001), Campagna *et al.* (2010), Chubb (1921b), Klicka *et al.* (2007), McCarthy (2006), Meyer de Schauensee (1952a), Ouellet (1992), Restall *et al.* (2006), Ridgely & Tudor (1989), Short (1969).



283. Chestnut Seedeater

Sporophila cinnamomea

French: Sporophile cannelle **German**: Zimtpfäffchen **Spanish**: Semillero Castaño
Other common names: Grey-capped Chestnut Seedeater; Narosky's/Entre Rios Seedeater ("*S. zelichi*")

Taxonomy. *Pyrrhula cinnamomea* Lafresnaye, 1839, River Araguaia, Goiás, Brazil.
Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris* and *S. melanogaster*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Form described as *S. zelichi* (from Entre Ríos, in NE Argentina) considered to be a white-necked morph of *S. palustris* or possibly a hybrid between latter and present species. Monotypic.

Distribution. Breeds in NE Argentina (Corrientes and Entre Ríos), extreme SE Paraguay (Itapúa), extreme SE Brazil (W & SC Rio Grande do Sul) and W & SE Uruguay (mostly Paysandú, Río Negro and Rocha, also Artigas, Soriano and Treinta y Tres). Migrates N as far as SC Brazil (Goiás, SE Mato Grosso and W Minas Gerais).

Descriptive notes. 10 cm. A tiny, small-billed and relatively long-tailed seedeater. Male has distinctive grey cap, rest of head, neck, entire upperparts, throat and entire underparts chestnut (some seemingly adult males have pale feather tipping on underparts, giving patchy appearance, also some have entirely chestnut undertail-coverts, while others whitish from here to vent); tail contrastingly blackish, some grey edging on rectrices; upperwing also blackish, lesser upperwing-coverts blue-grey (creating greyish shoulder), remaining coverts edged grey, tertials more widely grey-edged, a noticeable white patch at base of primaries; iris dark brown; bill and legs black. Female is relatively warm-coloured, warm sandy brown above, face uniformly buff, dark eye prominent; upperwing and tail darker, wing-coverts with sandy-brown edging (on some appears as two dull sandy wingbars when plumage fresh); warm buff below, whitish on belly, and sometimes on middle of throat and breast; bill dark horn to blackish, legs blackish. Juvenile is very like female; young male in later stages darker on upperparts, buffier on underparts, eventually dark feathers begin to appear on upperparts and white ones on throat. Voice. Song sweet, melodious and pleasant, composed largely of sweet descending whistles, with some more nasal or slightly warbled notes, "tweew tii-tweeew tweew, peew put-tweew tuu-twii nhhhnhhh tweew..."; overall slightly lower-pitched and more nasal in quality than song of closely related *S. palustris*. Call typically a sweet descending whistle, "twéeeeeww".

Habitat. Tall grassland adjacent to moist swales, moist shrubby marsh or wet savanna. In study in Argentina, found in undulating grassland 73·5% of time, in marsh or wet grassland 14·7%, and in cardal–caraguatal (*Cardus–Eryngium horridum*) thickets 11·7% of time.

Food and Feeding. Grass seeds. Clings to grass stem as it removes seeds. Forages in small groups or in mixed flocks with other seedeater species; in non-breeding season in larger flocks with various other members of genus.

Breeding. Season Dec–Feb. Nest a woven cup of dry grass, often very pale in colour, and translucent owing to thin nature of nest bottom. Clutch 3 eggs, white with grey, brown and blackish markings, these largely around wide end. No other information.

Movements. Migratory; breeds during austral spring and summer, then migrates N. Details of migration remain to be determined.

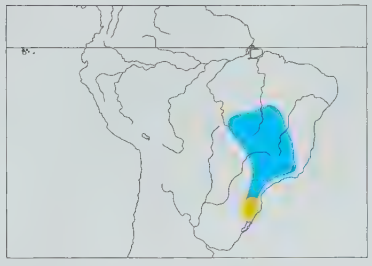
Status and Conservation. VULNERABLE. Locally fairly common; very patchily distributed. Has suffered rapid decline, and global population believed now to be small and fragmented. Main causes of decline are capture for the cagebird trade and degradation and loss of habitat. Illegal trapping has led to great reduction in numbers of this species in the wild, and alteration or loss of habitat owing to draining of wetlands, overgrazing and, primarily, the planting of exotic pines (*Pinus*) and eucalypts (*Eucalyptus*) has compounded the problem. Has been suggested that small grassland patches adjacent to these tree plantations may attract grassland birds such as seedeaters, but that reproductive rates there may be lower than in large patches of grassland, effectively creating a population sink in these areas. In addition, pesticides and other harmful chemicals enter marshes, and invasive grasses and annual burning are a further threat to habitats in non-breeding period. In S Paraguay seasonally inundated grasslands and marshes have been converted to rice fields, but effect, positive or negative, of rice-farming unknown. In Argentina, where trapping prohibited, this species breeds in El Palmar National Park; trapping prohibited also in Uruguay, but illegal trade continues, especially along R Uruguay basin; legally protected in Paraguay, where it

occurs in two protected sectors of San Rafael National Park. Protected by law in Brazil, and occurs in Das Emas (Goiás) and Ilha Grande National Parks (Paraná–Mato Grosso do Sul border), Itirapina Ecological Station (São Paulo) and São Donato Biological Reserve (Rio Grande do Sul); non-breeding visitors numerous only at Das Emas National Park.

Bibliography. Anon. (2010c), Areta (2008), Armani (1985), Butchart & Stattersfield (2004), Campagna *et al.* (2010), Canevari *et al.* (1991), Di Giacomo, A.S. *et al.* (2010), Klicka *et al.* (2007), Lopes *et al.* (2010), Meyer de Schauensee (1952a), Narosky (1975), Ouellet (1992), Ridgely & Tudor (1989), Stattersfield & Capper (2000).

284. **Black-bellied Seedeater**

Sporophila melanogaster



French: Sporophile à ventre noir **Spanish**: Semillero Ventrinegro
German: Schwarzbauchpfäffchen

Taxonomy. *Spermophila melanogaster* Pelzeln, 1870, Itararé and Resaca, São Paulo, Brazil.

Molecular evidence suggests that genus is closely related to *Oryzoborus*, which should perhaps be subsumed within it; further, that both genera should be placed in the tanager family (Thraupidae). A molecular-genetic study of 17 species in genus, including ten in "capped" group ("capuchinos"), indicated that latter form two clades, a N clade largely N of R Amazon containing *S. minuta* and *S. castaneiventris*, and a S clade consisting of present species and *S. bouvreuil*, *S. hypoxantha*, *S. hypochroma*, *S. ruficollis*, *S. palustris* and *S. cinnamomea*. Determination of relationships within the S clade not possible, as genetic differentiation very low and species are apparently part of a very recent and rapid radiation. Monotypic.

Distribution. Breeds in SE Brazil (E Santa Catarina and NE Rio Grande do Sul); migrates N as far as C Goiás and W Minas Gerais.

Descriptive notes. 10 cm; 8–10·5 g. Typical seedeater in shape and small size, with stubby, rounded bill. Male breeding has head down to malar region blue-grey, sometimes with tiny white spot by base of lower mandible, neck and upperparts similarly blue-grey; tail blackish, pale grey edging at base of outer rectrices; upperwing also blackish, feathers edged grey, particularly on tertials, narrow greyish wingbars sometimes apparent, small white patch on primary bases; throat black, black continuing along centre of breast, broadening into largely black belly and continuing to all-black vent and undertail-coverts, with flanks blue-grey (similar in colour to upperparts); iris dark brown; bill and legs black. Male non-breeding moults into female-like plumage, and bill becomes more yellowish. Newly described morph ("*xumanxu*") is almost entirely black, apart from grey cap and

greyish feather edgings on wings. Female is relatively warm-coloured, warm sandy brown above, face uniformly buff, dark eye showing prominently; upperwing and tail darker; warm buff below, palest on belly and sometimes on middle of throat and breast; bill dark horn to blackish, legs blackish. Juvenile and immatures not well known; presumably much like female, and older immature males beginning to show traces of adult plumage. Voice. Song begins with one or two buzzy trills followed by a long, high descending note, which sounds as if divided into three parts, "twah-wah-weew"; final section of song is continued by rhythmic sequence of clear notes, normally alternating with very characteristic rough "chirp" notes. Also pairs of descending whistles or single whistles with moderately long intervals between them, "tweeooo-twi... cheeeooooo...tweeoooo...". Call a short "thwup" or "chip".

Habitat. Old tall grassland adjacent to wetlands or moist swales, at 700–1000 m; lower in non-breeding season.

Food and Feeding. Grass seeds. Clings to grass stem while extracting the seeds. Forages in pairs and in small groups.

Breeding. Season Nov–Mar. No other information.

Movements. Migratory; arrival on breeding grounds in Oct–Nov, departure Feb–Mar. Details of migration remain to be determined.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally common; has tiny breeding range. Thought to be undergoing a moderately rapid population decline, largely as a result of decrease in area of habitat. Grasslands continue to be converted to cattle ranching, invasive grasses are becoming ever commoner, and other agriculture is encroaching. Pesticides noted as a potential problem. Surveys required in order to ascertain full extent of this species' range, particularly during non-breeding season; its ecological requirements and extent to which it tolerates agricultural habitats need also to be determined. Effective protection of significant areas of suitable grassland habitat at key sites needs to be ensured.

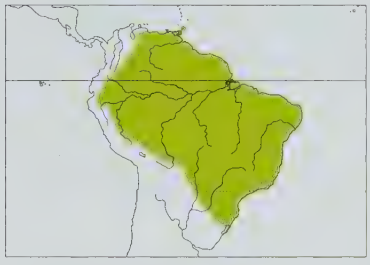
Genus *ORYZOBORUS* Cabanis, 1851

285. **Thick-billed Seed-finch**

Oryzoborus funereus

French: Sporophile à bec fort **Spanish**: Semillero Piquigrueso
German: Dickschnabel-Reisknacker
Other common names: Lesser Rice Grosbeak, Lesser Seed-finch (when treated as conspecific with *O. angolensis*)

Taxonomy. *Oryzoborus angolensis funereus* P. L. Sclater, 1860, Suchapam, Oaxaca, Mexico.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Present species commonly treated as conspecific with *O. angolensis*; they hybridize in S Colombia (upper Magdalena Valley), but apparently only to a limited extent. Four subspecies recognized.
Subspecies and Distribution.
O. f. funereus P. L. Sclater, 1860 – SE Mexico (S Veracruz) S in Caribbean lowlands to Nicaragua.
O. f. salvini Ridgway, 1884 – S Nicaragua, Costa Rica (except extreme SW) and Caribbean coast of Panama.
O. f. ochrogyne Olson, 1981 – SW Costa Rica, and Pacific slope of Panama, including Coiba I (off S Veraguas) to W & N Colombia (E to Magdalena Valley and Guajira Peninsula) and extreme NW Venezuela (W shores of L Maracaibo).
O. f. aethiops P. L. Sclater, 1860 – SW Colombia (Nariño) and W Ecuador.



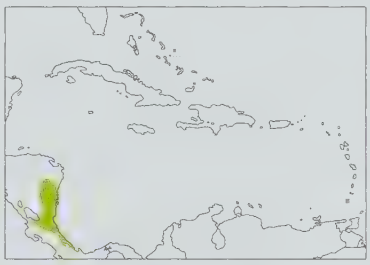
Descriptive notes. 10·7–12·5 cm; 12·8–13·9 g. Small, with large, very deep-based bill (larger than *Sporophila*). Male nominate race is all black, except for white at bases of primaries and secondaries (mostly concealed), and white underwing-coverts; iris black; bill and legs blackish. Female is dark brown above, paler cinnamon-brown below, lacks white in primaries; bare parts as for male. Juvenile is like female. Races differ in depth of colour of females and subadult males: *salvini* is much more richly coloured than others, with underparts deep reddish-chestnut; *aethiops* is similar to previous, but more sooty (less reddish) above and below; *ochrogyne* is much paler than others. Voice. A series of sweet, slurred whistles and warbles, "techu techu chu chi techu chu chi...", duration 4–20 seconds. Call a slurred "tchew" or staccato "dik".
Habitat. Humid forest edge, grassy and shrubby fields with scattered shrubs and trees, second growth and tall grass; usually found in scrub in grassy areas; more arboreal than other seedeaters. Lowlands to 1100 m, usually below 500 m.
Food and Feeding. Feeds on grass seeds, including hard-shelled seeds of a grass in genus *Olyra*. Forages in dense vegetation; flicks wings and tail in nervous manner. Singly and in pairs; sometimes in small groups, occasionally with other seed-finches.
Breeding. Season Apr–Sept in Middle America and May–Oct in Colombia. Nest a slight cup of rootlets, fibres and grasses, lined with finer rootlets and spider webs, placed up to 1 m above ground or water in bush, dense tree or vine tangle. Clutch 2–3 eggs, dull greenish-white, heavily spotted with brown or lilac. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally fairly common; common on Coiba I, off S Panama; uncommon to rare in Mexico. Apparently increasing in numbers in Darién, Panama, following clearing of forest.
Bibliography. Armani (1985), Howell & Webb (1995), McCarthy (2006), Miller *et al.* (1957), Monroe (1968), Olson (1981a, 1981e), Ridgely & Gwynne (1989), Ridgway (1901), Stiles & Skutch (1989), Wetmore *et al.* (1984).

286. **Chestnut-bellied Seed-finch**

Oryzoborus angolensis

French: Sporophile curio **German**: Braunbauch-Reisknacker **Spanish**: Semillero Curió
Other common names: Lesser Rice Grosbeak, Lesser Seed-Finch (when treated as conspecific with *O. funereus*)

Taxonomy. *Loxia angolensis* Linnaeus, 1766, Angola; error = eastern Brazil.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Present species commonly treated as conspecific with *O. funereus*; they hybridize in S Colombia (upper Magdalena Valley), but apparently only to a limited extent. Proposed race *theobromae* (known from two specimens from upper Magdalena Valley in Tolima and Huila, in Colombia) is synonymized with *torridus*. Two subspecies recognized.
Subspecies and Distribution.
O. a. torridus (Scopoli, 1769) – E & SE Colombia, Venezuela, Trinidad and Tobago, the Guianas, and Amazonian Brazil S to lowlands of E Ecuador and E Peru.
O. a. angolensis (Linnaeus, 1766) – C & E Brazil (Mato Grosso, Goiás and Piauí S to Rio Grande do Sul) to N & E Bolivia (Beni and Santa Cruz), Paraguay and extreme NE Argentina (Misiones).
Descriptive notes. 10·6–12·4 cm; 11·4–14·5 g. A medium-sized, heavy-billed finch. Male has entire head down to breast and all of upperparts, including tail, black; upperwing also black, except for a small, well-formed white patch at base of primaries; black of breast stops abruptly, changing to deep chestnut that continues to undertail-coverts; flanks also chestnut, thighs black; wing-linings brilliant white, this extending to marginal wing-coverts (often visible on perched bird); iris lack; bill and legs black. Female is nondescript, lacking distinct patterns on face and wing; entirely warm brown above, upperwing and tail brown like upperparts; pale cinnamon below, darkest on breast



and nearly whitish on chin; wing-linings bright white, as on male; bill dark, legs dusky. Juvenile is like female. Race *torridus* is smaller than nominate, smaller-billed and relatively short-tailed. Voice. Song a fairly long series of musical whistled notes, interspersed with chattering notes, and often ending in trills; quite variable. Call a single liquid whistle.
Habitat. Shrubby or grassy clearings in forest and edges, deciduous forest and second growth. Sea-level to 1600 m.
Food and Feeding. Little information. Diet seeds and insects. Gleans grass seeds by clinging to long stems that bend over, or by hopping on ground. Generally singly or in pairs; occasionally joins flocks of other seedeaters.
Breeding. Season Feb–Aug in N and Sept–Feb in S. Nest flimsy, a deep cup of fine reddish grasses and vines, usually placed fairly near ground. Clutch 2 eggs, sometimes 3. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally fairly common in most parts of its very large range. Rare in Trinidad. Records from Tobago are thought to refer to escaped captives. Highly prized as a cagebird because of its song, and often trapped. Formerly widespread and common in Trinidad, but numbers there greatly reduced by trapping and now rare.
Bibliography. Armani (1985), Dunning (2008), ffrench (1991), Hilty (2003), Lill (1974), McCarthy (2006), Miller (1982), Olson (1981a, 1981e), Restall (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Ridgway (1901).

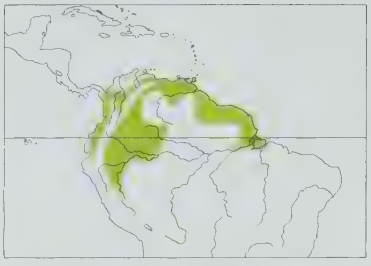
287. **Nicaraguan Seed-finch**

Oryzoborus nuttingi

French: Sporophile de Nutting **Spanish**: Semillero Nicaragüense
German: Rosenschnabel-Reisknacker
Other common names: Pink-billed Seed-finch, Nutting's Rice Grosbeak

Taxonomy. *Oryzoborus nuttingi* Ridgway, 1884, Los Sábalos (River San Juan), Nicaragua.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Formerly considered conspecific with *O. crassirostris*, *O. maximiliani* and *O. atrirostris*; still included by some authors in *O. maximiliani*, but by others considered closest to *O. crassirostris*; taxonomy of this group still in flux. Monotypic.
Distribution. Caribbean lowlands of Nicaragua, N & E Costa Rica (including Laguna de Arenal, near Finca La Selva) and W Panama (Almirante region of Bocas del Toro).

Descriptive notes. 14–14·5 cm; 24 g. Medium-sized finch with massive bill. Male is all black; iris blackish; bill pale pinkish; legs lead-grey. Female is slightly smaller than male, dark brown above, rump and uppertail-coverts paler than back; paler warm brown on ventral surface; bill blackish. Juvenile is like female. Voice. Male's song, from tree or shrub overlooking grassy breeding site, or in flight, a series of slurred whistled notes, slower, deeper and richer than song of *O. funereus*. Call a short, sharp "check".
Habitat. Wet grassy areas, usually near water; 500–900 m.
Food and Feeding. Feeds mostly on grass seeds. When not breeding may be found in small flocks, sometimes with other seed-eating finches.
Breeding. Season Feb–Jul. Nest a flimsy cup of fibres and grasses, lined with finer rootlets and spider webs, placed fairly low over ground or water in bush or other vegetation. Clutch 2 eggs, greenish-white with brown spots. No other information.
Movements. Resident; apparently moves in response to available food.
Status and Conservation. Not globally threatened. Uncommon; local. Has apparently expanded its range S from S Nicaragua in recent years.
Bibliography. Armani (1985), Olson (1981a), Ridgway (1901), Stiles (1984), Stiles & Skutch (1989), Wetmore *et al.* (1984).



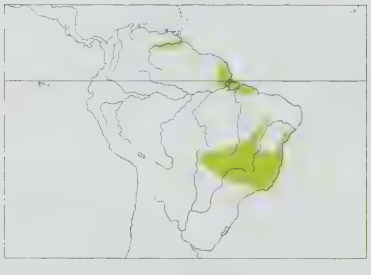
288. **Large-billed Seed-finch**

Oryzoborus crassirostris

French: Sporophile crassirostre **German**: Mohrenreisknacker **Spanish**: Semillero Piquigrande

Taxonomy. *Loxia crassirostris* J. F. Gmelin, 1789, no locality = Cayenne, French Guiana.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Formerly considered conspecific with *O. nuttingi*, *O. maximiliani* and *O. atrirostris*; race *occidentalis* often placed in *O. maximiliani*; taxonomy of this group still in flux. Two subspecies recognized.
Subspecies and Distribution.
O. c. occidentalis P. L. Sclater, 1860 – Pacific slope of Colombia S to SW Ecuador.
O. c. crassirostris (J. F. Gmelin, 1789) – Venezuela, the Guianas, E Colombia S to NE Peru, and N & W Brazil (NW Amazonas, NE Roraima, Amapá and N Pará); also Trinidad (at least formerly).
Descriptive notes. 13·5–14·5 cm; two birds 19·8 g and 22 g (nominate), 22–28·4 g (*occidentalis*). A medium-sized finch with proportionately long tail and enormous bill for its body size; bill so deep that crown appears to sweep back from base of upper mandible, giving flat-headed look. Male nominate race is almost entirely black and lacking noticeable gloss; white patch at base of primaries; wing-

On following pages: 289. Great-billed Seed-finch (*Oryzoborus maximiliani*); 290. Black-billed Seed-finch (*Oryzoborus atrirostris*); 291. White-naped Seedeater (*Dolospingus fringilloides*); 292. Blue Seedeater (*Amaurospiza concolor*); 293. Blackish-blue Seedeater (*Amaurospiza moesta*); 294. Carrizal Seedeater (*Amaurospiza carrizalensis*).

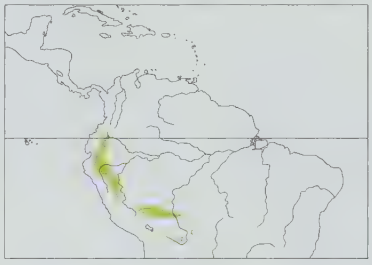


linings white; iris very dark; bill ivory-white, glossy; legs black. Distinguished from very similar *O. maximiliani* by smaller size and less massive bill, also by often cleaner-looking bill; from *O. atrirostris* also by paler bill. Female is warm brown above, slightly darker on plain wings and tail, paler buff-brown below; white wing-linings; bill blackish, legs dark. Juvenile is like female, but young male with slightly streaked head and darker wings, as well as paler throat and horn-coloured bill. Race *occidentalis* differs in having smaller white primary patch and darker underwing. VOICE. Song (race *occidentalis*) lasts 4–5 seconds, a couple of introductory notes followed by rich gurgling series of rapidly delivered notes; overall effect similar to that of song of Bobolink (*Dolichonyx oryzivorus*). May give a flight song which is much more complex and longer than perched song. Call a sharp "chwit!" or "tchweet!", with explosive quality.
Habitat. Usually found near water in shrubby areas adjacent to marshes, as well as tall emergent vegetation by rivers, swamps and lakes; also damp pastures and tall moist grassy areas. Sea-level to 500 m.
Food and Feeding. Seeds; perhaps particularly well adapted to feeding on seeds of large sedges (Cyperaceae). Probably some insects taken. Forages by perching on stem or adjacent stem to reach seedheads; also on ground. Searches in rice paddies. Singly and in pairs; sometimes in small flocks.
Breeding. Nests found in May and possibly Sept in Trinidad. Nest a well-constructed but loose cup-shaped structure of stalks and grass, lined with softer material, greenish moss around rim, placed fairly low in shrub. Clutch 2–3 eggs, cream-coloured and spotted with dark brown; incubation by female, period 12 days; chicks fed by both male and female. No further information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally uncommon, and local. Numbers of this species have been greatly depleted by trapping for the cagebird trade. Appears to be localized and scarce in most of its range; very rare in French Guiana and increasingly so in Suriname and Guyana, where trapping most severe; very uncommon in Brazil; perhaps still locally fairly common in Colombia. Could become threatened in the future; monitoring required.
Bibliography. Armani (1985), Ffrench (1991), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Lill (1974), McCarthy (2006), Meyer de Schauensee (1970b), Miller (1982), Olson (1981a), Restall *et al.* (2006), Ridgely & Tudor (1989), Robbins *et al.* (2005), Sick (1993).

289. **Great-billed Seed-finch**
Oryzoborus maximiliani

French: Sporophile de Maximilien **Spanish**: Semillero de Maximilian
German: Maximilianreisknacker
Other common names: Greater Seed-finch

Taxonomy. *Oryzoborus maximiliani* Cabanis, 1851, River Espírito Santo, Espírito Santo, and Caravellas, Bahia, Brazil.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Formerly considered conspecific with *O. nuttingi*, *O. crassirostris* and *O. atrirostris*; race *occidentalis* of *O. crassirostris* often placed in present species; taxonomy of this group still in flux. If present species is placed in genus *Sporophila*, name *magnirostris* becomes preoccupied, and must be replaced by *parkesi*. Two subspecies recognized.
Subspecies and Distribution.
O. m. magnirostris Phelps, Sr & Phelps, Jr, 1950 – E Venezuela (SE Sucre S to Delta Amacuro, and N Bolivar along S bank of R Orinoco), W Guyana and E French Guiana to N Brazil (Amapá and N Pará).
O. m. maximiliani Cabanis, 1851 – C & E Brazil (N Goiás, C Piauí and Bahia S to C Mato Grosso and N São Paulo).

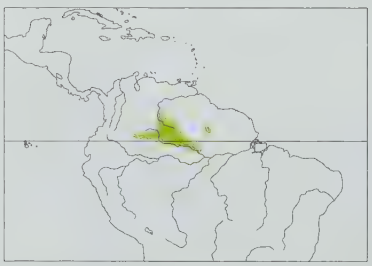


Descriptive notes. 14·5–16·5 cm. A medium-sized finch with proportionately long tail and enormous bill; bill so deep that crown appears to sweep back from base of upper mandible, giving flat-headed look. Male is black with dull blue gloss, except for noticeable white patch at base of primaries; wing-linings also white; iris very dark; bill ivory-white, worn and uneven-looking in texture, often with diagonal ridges or lines; legs black. Distinguished from very similar *O. crassirostris* by larger size, also proportionately larger bill looking worn and less neat (not shiny and smooth). Female is warm brown above and paler buff-brown below, wings and tail slightly darker than upperparts and lacking any pale bars or patches, wing-linings white; bill black; legs dusky. Juvenile is like female, but juvenile male slightly streaked on head, with darker wings, paler throat and horn-coloured bill; male eventually moults some black feathers, retain patchy appearance for several months before becoming entirely black. Race *magnirostris* has slightly longer wing and tail, and bill averages c. 20% longer. VOICE. Song rapid and flute-like, jumping from high notes to low notes and sometimes having metallic timbre, usually 2–3 sweet whistles and a rattled trill followed by many musical notes; female known to sing, and at times as accomplished as male. Song types vary geographically. Call a loud "jep" or "chok".
Habitat. Usually found near water in shrubby areas adjacent to marshes (riparian thickets), as well as tall emergent vegetation by rivers, swamps and lakes; also damp pastures and tall moist grassy areas. Lowlands.
Food and Feeding. Little known. Forages largely for seeds; usually found in pairs, and does not form flocks.
Breeding. Singing in Aug in NE Venezuela. Male performs aerial display, with song; also a wing-raising display to show normally hidden white underwing to female during presumed breeding season. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to rare, and local; possibly not uncommon in parts of NE Venezuela; very rare in Brazil (where a significant captive population exists). Has suffered moderate population decline largely as a result of trapping for the cagebird trade, also of habitat loss through large-scale deforestation. This species is widely coveted by cagebird-fanciers because of its singing ability; numbers seriously depleted by trapping, but effect is patchy and local. In Brazil, occurs in Das Emas National Park (Goiás).
Bibliography. Anon. (2010c), Butchart & Stattersfield (2004), Klicka *et al.* (2007), Lijtmaer *et al.* (2004), McCarthy (2006), Meyer de Schauensee (1970b), Olson (1981a), Restall *et al.* (2006), Ridgely & Tudor (1989), Robbins *et al.* (2005), Sick (1993), Tostes (2003).

290. **Black-billed Seed-finch**
Oryzoborus atrirostris

French: Sporophile à bec noir **Spanish**: Semillero Piquinegro
German: Schwarzschnabel-Reisknacker
Other common names: Peruvian Seed-finch

Taxonomy. *Oryzoborus atrirostris* P. L. Sclater and Salvin, 1878, Moyobamba, San Martín, Peru.
Genus sometimes subsumed in *Sporophila*. Molecular evidence suggests that genus as currently constituted may not be monophyletic, and some of its members may have closest relatives in *Sporophila*; more data necessary in order to resolve a basal polytomy in the phylogeny. Formerly considered conspecific with *O. nuttingi*, *O. crassirostris* and *O. maximiliani*; taxonomy of this group still in flux. Races weakly differentiated, and larger bill of *gigantirostris* may be individually variable; species perhaps better treated as monotypic. Two subspecies tentatively recognized.
Subspecies and Distribution.
O. a. atrirostris P. L. Sclater & Salvin, 1878 – locally in extreme S Colombia, E lowlands of Ecuador and E Andean slopes in N Peru (San Martín, Loreto and Ucayali).
O. a. gigantirostris J. Bond & Meyer de Schauensee, 1939 – SE Peru (Madre de Dios) and N & E Bolivia (Beni; isolated records in W & C Santa Cruz).



Descriptive notes. 15–16·5 cm; two males 23 g and 29 g (*gigantirostris*). A medium-sized finch with proportionately long tail and enormous bill for its body size; bill so deep that crown appears to sweep back from base of upper mandible, giving flat-headed look. Male is almost entirely black and without noticeable gloss; some white at primary bases, often very restricted (variable); white wing-linings; iris very dark; bill black; legs dusky or dark grey. Female is warm brown above, slightly paler brown below, with wings and tail slightly darker than upperparts; paler, whitish wing-linings; bare parts much as for male. Juvenile is like female, but young male slightly streaked on head and with darker wings, paler throat and horn-coloured bill. Race *gigantirostris* is very like nominate, but bill supposedly even bigger. VOICE. Song a rich and leisurely warbling composed of many rich whistles; no other information.
Habitat. Grassy areas and clearings in marshy areas, or adjacent to riparian forest, lakes reedbeds, or aquatic thickets. Lowlands.
Food and Feeding. Diet presumably seeds. Forages singly and in pairs. No other information.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Previously listed as Near-threatened; recently downgraded owing to better understanding of total population numbers. Uncommon to rare, and patchily distributed. Popular in captivity, and trapped for the cagebird trade. Should be monitored on a regular basis in order to guard against potential declines caused by trapping and habitat loss.
Bibliography. Klicka *et al.* (2007), Lijtmaer *et al.* (2004), Restall *et al.* (2006), Ridgely & Tudor (1989), Robbins *et al.* (2005).

Genus *DOLOSPINGUS* Elliot, 1871

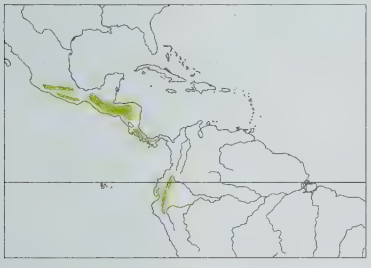
291. **White-naped Seedeater**
Dolospingus fringilloides

French: Sporophile à nuque blanche **Spanish**: Semillero Nuquiblanco
German: Spitzschnabelpfäffchen

Taxonomy. *Oryzoborus* (?) *fringilloides* Pelzeln, 1870, River Xié, upper River Negro, Brazil.
Molecular work indicates that genus is very closely related to *Sporophila* and should perhaps be merged with it; appears not to be close to *Catamenia* and some other genera with which it has been placed in the past. Monotypic.
Distribution. SE Colombia (Guainía and Vaupés), S Venezuela (Amazonas) and NW Brazil (N Amazonas E to Presidente Figueiredo); also S Guyana.

Descriptive notes. 13–13·5 cm; c. 12–13 g. A slim seedeater with elongate body structure, tail relatively long, long and triangular bill thick at base. Male has black hood reaching down to most of throat, noticeable white collar on nape (an extension of white underparts); upperparts black, rump white and contrasting with black uppertail-coverts and tail; upperwing black, median coverts white (forming bold and wide upper wingbar), greater coverts with restricted white wedge shaped markings at tips (rather broken-looking lower wingbar), white patch at base of primaries (normally concealed); throat and underparts white, small dark wedge on side of breast, sides and flanks sometimes pale greyish, flanks with obscure blackish blotching; pale underwing-coverts; iris dark brown; bill bright ivory-white with blue-grey tinge, particularly on

base of lower mandible; legs greyish to blackish. Female is dull brown on head, upperparts, wings and tail; below, brownish from throat and breast down to flanks, whitish belly contrasting with buffy undertail-coverts; bill brownish, legs blackish-brown. Juvenile is indistinguishable from female; older immature male darker brown than adult female, with black centres of crown feathering, black mottling on face and chin, indistinct brown breastband sprinkled with some black feathers, whitish lower breast and abdomen with some feather tips tinged buffy brown, also a white primary patch and wingbars. VOICE. Male song, from exposed perch (often tree snag) usually 2–4 m above ground, loud, fast and musical, with notes arranged in triplets, "ne-ne-ne, te-te-te, ge-ge-ge, jii-jii-jii, tué tué tué..."; some variations with longer notes, again usually tending to be in threes. Call a sharp "tzink!".
Habitat. Clearings with low scrub and isolated dead trees in white-sand forest, also taller forest edge, and grassy savannas of upper R Orinoco–R Negro watershed; often in ridgetop sand-forest vegetation in rocky outcroppings. Sea-level to 700 m.
Food and Feeding. Stomach contents reveal a mainly granivorous diet, but feeds also on insects; an observation of males and females foraging on mistletoe fruits (Loranthaceae). Forages up to 4 m high in dense vegetation. Singly and in pairs.
Breeding. Season appears to span Aug–Apr (end of rainy season to end of dry season) in S Guyana. No other information.
Movements. Not well known; presumably resident.
Status and Conservation. Not globally threatened. Relatively rare and little known. Recently discovered in extreme S Guyana, as well as in E Amazonas (Presidente Figueiredo), in Brazil. Has fairly large range, and no evidence of population declines. Given this species' habitat choice of white-sand forest, it should be monitored in case habitat fragmentation does begin to have adverse effects on its numbers.
Bibliography. Armani (1985), Newman (2000), Restall *et al.* (2006), Ridgely & Tudor (1989), Robbins *et al.* (2005).



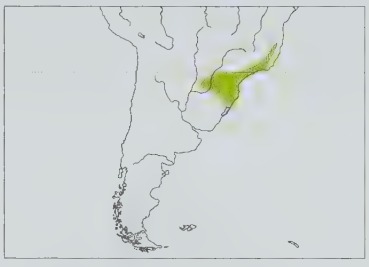
Genus *AMAUROSPIZA* Cabanis, 1861

292. **Blue Seedeater**

Amaurospiza concolor

French: Sporophile bleu **German**: Indigopfäffchen **Spanish**: Semillero Azul
Other common names: Cabanis's Seedeater; Slate-blue Seedeater (*relicta*)

Taxonomy. *Amaurospiza concolor* Cabanis, 1861, Costa Rica.
Molecular data indicate that genus may belong in the cardinal family (Cardinalidae), rather than in present one. Race *relicta* sometimes treated as a separate species. Proposed race *grandior* (described from Peña Blanca, in E Nicaragua) synonymized with nominate. Three subspecies recognized.
Subspecies and Distribution.
A. c. relicta (Griscom, 1934) – mountains of Guerrero, Morelos and Oaxaca, in SW Mexico.
A. c. concolor Cabanis, 1861 – S Mexico (Chiapas), Honduras, Nicaragua, Costa Rica and W & C Panama.
A. c. aequatorialis Sharpe, 1888 – SW Colombia (Nariño), W & C Ecuador (SW Manabí and W Guayas; W slope of Andes S locally to Loja) and N Peru (Cajamarca, possibly also Piura).



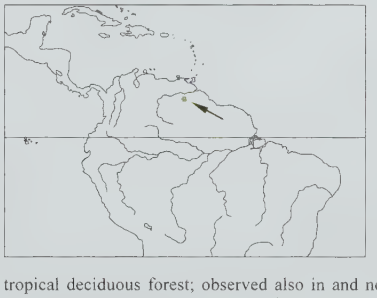
Descriptive notes. 11·5 cm; 12–15 g. A small, thickset finch, bill slightly longer than it is deep and with slightly rounded culmen. Male nominate race is almost entirely dark greyish-blue with very weak iridescence; upperwing and tail blackish-brown with dark bluish edging; plumage very uniform, only slightly paler on belly; iris dark; bill greyish; legs blackish. Distinguished from *Volatinia jacarina* by larger size, deeper bill, and lack of blackish and deeply iridescent plumage. Female is nondescript, lacking distinctive features; entirely warm brown with chestnut tone, very uniform other than slightly paler throat and belly; upperwing brown, chestnut-brown edging on remiges, entirely chestnut-brown coverts like rest of upperparts; wing-linings slightly paler cinnamon-brown, this extending to marginal coverts (may show paler edge of shoulder when perched); tail brown with chestnut-brown fringes; bill dark horn. Juvenile is like female, but somewhat more rufescent below, and has fairly conspicuous buffy wingbars. Race *relicta* is larger, female colder brown; *aequatorialis* is smaller, paler and duller than nominate. VOICE. Song a brief, fast, jumbled warble with sweet quality, "sweet-sweet-sweet-saweet" or "chi chi whee chee chee". Call a sharp "hu-tsset" or "chu-tsee".
Habitat. Overgrown forest borders and secondary woodland; in Mexico (Oaxaca) reported also in humid pine–oak (*Pinus–Quercus*) woodlands or cloudforest. Usually found in association with *Chusquea* bamboo in Costa Rica and Panama; in Ecuador may be found in bamboo, but can occur in other places. At 450–2000 m in N of range, race *relicta* 1200–2500 m; 1000–2200 m in Costa Rica, and to 2700 m in Panama; mainly 1100–2300 m in Ecuador.
Food and Feeding. Feeds on tender growing stem tips of bamboo; also insects and seeds. Forages from low levels (1–2 m) to up to 10 m in dense vegetation; hops and flits in foliage of bamboo. Singly and in pairs or family groups; sometimes in small mixed-species flocks.
Breeding. Breeds mostly in May and Jun; in Jul in Morelos (Mexico); fledglings reported in early Sept in Costa Rica. Nest a cup of coarse grasses, lined with finer grasses, placed 2·5–3 m up in fork of a forb (*Lantana*). Clutch 2 eggs, unmarked pale blue. No other information.
Movements. Resident; wanders irruptively in search of seeding bamboo.
Status and Conservation. Not globally threatened. Not well known. Apparently rare and local throughout its range. Available information suggests that this species' population is stable.
Bibliography. Armani (1985), Binford (1989), Butchart & Stattersfield (2004), Davidson (1938), Griscom (1934), Howell & Webb (1995), Klicka *et al.* (2007), Miller *et al.* (1957), Monroe (1968), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Ridgway (1901), Rowley (1962), Schaldach (1973), Stattersfield & Capper (2000), Stiles & Skutch (1989), Vallely & Aversa (1997), Wetmore *et al.* (1984).

293. **Blackish-blue Seedeater**

Amaurospiza moesta

French: Sporophile noirâtre **German**: Weißachselpfäffchen **Spanish**: Semillero Negruzco

Taxonomy. *Sporophila moesta* Hartlaub, 1853, Brazil.
Molecular data indicate that genus may belong in the cardinal family (Cardinalidae), rather than in present one. Monotypic.
Distribution. SE Brazil (S Espírito Santo S to Paraná and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).



Descriptive notes. 12·5 cm; 13–14·5 g. A small and compact finch with proportionately small head and short tail; bill relatively small and triangular, with slightly curved culmen. Male is dark slaty blue all over, blacker on foreface and underparts, with wing-linings white; iris dark brown; bill black, lower mandible sometimes dark greyish; legs reddish-grey to blackish. Female is tawny-brown, slightly paler on underparts, with white wing-linings; bill black, horn-coloured base of lower mandible, legs black. Juvenile apparently undescribed. VOICE. Song a pleasant warble, "swee-swee-swi-sweeseeseeu" or "tseeo tsee tsu tsee tit", variable, but always quickly delivered; tonal quality suggest song of Ultramarine Grosbeak (*Cyanocompsa brissonii*). Call "psit" or "pix".
Habitat. Undergrowth of tropical forest and woodland, especially where bamboo (of genera *Chusquea* and *Guadua*) common; particularly likes forest edge, where middle levels and understorey thick. Will also accept forests with admixture of *Araucaria angustifolia*. Sea-level to 1600 m.
Food and Feeding. Seeds of bamboo, also other seeds, and insects; has been observed to eat leaf petioles of bamboo. Forages usually c. 2–3 m above ground, not higher up in trees; sometimes on the ground. Singly or in pairs.
Breeding. Males and females in breeding condition between late Aug and mid-Sept, as well as mid-Apr, in SE Brazil; wide span of dates suggests that breeding may be timed to coincide with seed availability, rather than any specific time of year. No other information.
Movements. Resident; partly nomadic in search of seeding bamboo, but can be found in areas also when bamboo not seeding.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Tends to be rare; not common anywhere. In Brazil, relatively common in Serra do Mar and Paraná, very local elsewhere; in Paraguay, rare and recorded at few sites; in Argentina, locally common, especially in highlands. In Brazil, one historical record from Maranhão, well N of current range, and reported also from Tocantins, also to N of present known range. A bamboo associate, increasing in numbers when seeding bamboo available, but not dependent on bamboo. Has been suggested that this species' population is in gradual decline owing to continuing habitat degradation and loss. Extensive tracts of montane forest still exist within this species' range, especially in São Paulo, but lowland Atlantic Forest now severely degraded and further threatened by agricultural expansion, human colonization, urbanization, industrialization and associated road-building. Populations at known sites should be monitored in order to determine trends and rates of range contraction; also, ecological studies needed to ascertain this species' precise habitat requirements and its levels of tolerance of habitat degradation and fragmentation. Suitable habitat should be afforded official protection.

294. **Carrizal Seedeater**

Amaurospiza carrizalensis

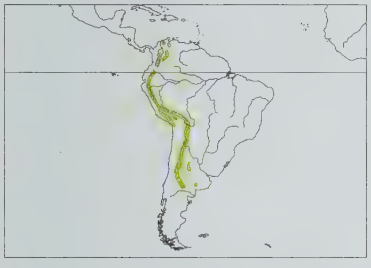
French: Sporophile de Carrizal **German**: Carrizalpfäffchen **Spanish**: Semillero de Carrizal

Taxonomy. *Amaurospiza carrizalensis* Lentino and Restall, 2003, Isla Carrizal, River Caroní, Bolívar, Venezuela. Molecular data indicate that genus may belong in the cardinal family (Cardinalidae), rather than in present one. Monotypic.
Distribution. Lower R Caroní basin (N Bolívar), in Venezuela.

Descriptive notes. 12 cm; 12–14 g. A compact finch, with bill of substantial size and with slightly curved culmen, the longest-billed of the genus; cutting edge of bill bends downwards near base. Male is dark slaty with strong blue gloss, blacker on face and underparts; wing-linings white; iris dark; bill and legs black. Female is warm brown above, paler ochraceous buff on underparts, darker on flanks; creamy-buff wing-linings; olive-grey base of lower mandible, legs dark grey. VOICE. Song a pleasant whistled warble, "sweet sweet pit-swee pit-swoo".
Habitat. Stands of spiny *Guadua latifolia* bamboo and *Ripidocladus* bamboo within tropical deciduous forest; observed also in and near *Guadua angustifolia* stands.
Food and Feeding. Crop contents of the type series included insects, as well as vegetable items; insects appeared to be beetles of family Curculionidae. No other information.
Breeding. No information.
Movements. No information.
Status and Conservation. CRITICALLY ENDANGERED. Recently discovered species, confined to tiny area of Venezuela. Very poorly known. Nowhere common, and global range appears to be tiny. Area of type locality now flooded; since initial description of this species, it has been found at an additional seven sites in lower R Caroní basin. Believed to have an extremely small population and to be declining because of continuing destruction of other potentially suitable habitat. Entire habitat at type locality was destroyed during development of Guri Dam, which not only caused this site to be flooded, but in addition destroyed other potentially suitable habitat in the vicinity. Main threat to existing populations is the total clearance of forest. Extreme scarcity of records possibly due partly to the difficulties of surveying its habitat. Following destruction of habitat at type locality, four organizations (three of them conservation-oriented, the other a commercial hydro-electric company) set up a two-year project to identify, locate and survey potential habitat for this species. The spiny bamboo in which it was initially discovered is an extremely dangerous habitat in which to conduct surveys; moreover, as it lies beneath the forest canopy, this habitat cannot be detected by means of aerial survey. Effective protection of potentially suitable habitat is considered essential if this species is to survive in the future.
Bibliography. Anon. (2010c), Hirschfeld (2007), Lentino & Restall (2003).

PLATE 68

inches 3
cm 8



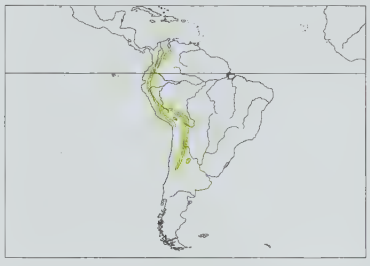
Genus *CATAMENIA* Bonaparte, 1850

295. Band-tailed Seedeater

Catamenia analis

French: Cataménie maculée **German**: Spiegelcatamenie **Spanish**: Semillero Colifajado

Taxonomy. *Linaria analis* d'Orbigny and Lafresnaye, 1837, Sicasica and Cochabamba, Bolivia.
Molecular data suggest that genus is part of a clade which includes *Haplospiza*, as well as *Phrygilus unicolor* and *Phrygilus plebejus* (but not other members of latter genus). Races divide into two fairly well-defined groups: southern "*analis* group" (nominate, *soderstomi*, *griseiventris*), with large and obvious wing stripe, and northern "*analoides* group" (*alpica*, *schistaceifrons*, *analoides*, *insignis*), with wingstripe less extensive or entirely lacking. Proposed race *subinsignis* (described from Sandillani, near La Paz city, in Bolivia) is synonymized with nominate. Seven subspecies currently recognized.
Subspecies and Distribution.
C. a. alpica Bangs, 1902 – Santa Marta Mts, in N Colombia.
C. a. schistaceifrons Chapman, 1915 – C parts of C & E Andes of Colombia.
C. a. soderstromi Chapman, 1924 – Ecuador (W slope and inter-Andean valleys).
C. a. analoides (Lafresnaye, 1847) – W slope of Andes of Peru (Piura S to Ayacucho).
C. a. griseiventris Chapman, 1919 – SW Peru (Cusco S to Tacna).
C. a. insignis J. T. Zimmer, 1930 – E slope of Peruvian Andes (Cajamarca S to Ancash).
C. a. analis (d'Orbigny & Lafresnaye, 1837) – extreme N Chile (Arica–Parinacota), highland Bolivia (La Paz E to W Santa Cruz, S to Tarija), and NW & EC Argentina (Jujuy and Salta S to Mendoza and La Pampa, and highlands of Córdoba; also Sierra de Ventana in SW Buenos Aires).



Descriptive notes. 12–14·5 cm; 10·3–16·6 g. A small emberizid with short conical bill as long as it is deep, but with only moderately rounded culmen. Male nominate race has head grey, at most indistinct streaking on crown, and typically darker blackish-grey around bill base; upperparts also grey, back with browner tone than crown and rump, the latter a purer blue-grey; tail blackish, bold white band across middle (band may be hidden by all-dark central rectrices when bird perched); upperwing blackish, grey fringes on coverts, cinnamon fringes on tertials, white bases of all primaries (showing as white patch on folded wing, white wingstripe in flight); underparts grey, paler than upperparts, becoming whitish-grey on middle of belly, contrasting with deep chestnut undertail-coverts; iris dark; bill yellowish; legs brownish-grey. Female is brown and streaked: head rather plain, lacking obvious supercilium or dark eyeline, and streaked throughout, streaking denser on crown, back warmer brown with dense dark brown streaks; tail brown with bold white band (band obvious in flight; visible also on underside of tail when bird perched); brown wings edged warmer cinnamon-brown, usually a small white or pale patch at base of primaries; throat, breast and flanks off-white with brown streaking, belly to undertail-coverts pale buffy white and unstreaked; bill horn-yellow with dark culmen and tip, legs greyish. Juvenile is like female, but much browner and more densely streaked both above and below; much variation in subadult plumages, apparently two immature (post-juvenile) stages in both sexes before adult plumage, male becomes progressively less streaked and more solidly darker greyish above and below, younger female more heavily streaked than older female, and adult female the most greyish and least streaked; more study needed to determine variation in this pattern (and, in particular, whether it applies throughout species' range). Races differ mainly in size, depth of plumage colours, and extent of wingstripe: *analoides* has white in wing restricted to inner web of each primary, but extending farther towards wingtip; *insignis* is more greyish below than previous, and lacks an obvious white wingstripe; *alpica* is large, has greyish around bill base (lacking black-faced look), little or no white at base of primaries (no obvious wingstripe), smaller tailband; *schistaceifrons* resembles last, but smaller, with bigger tailband; *soderstromi* is darker rufous on undertail-coverts, has white fringes on primaries, more extensive wingstripe (to outer primary webs); *griseiventris* is smaller than last, has more white on tail and is similarly greyish flanked, unlike warmer-toned *analoides*. Voice. Song a buzzy trill, "bzzzzzzzz" or "trrrrrrrr", lasting c. 1 second, repeated every 3–8 seconds, speed and pitch of trill variable, some males change from one trill type to another; some songs begin with very faint introductory note (followed by trill). At least in Argentina, also a complex song, a trill followed by a buzzy ascending note and then another trill on different pitch, "trrrrrrrrrr zwZZZZZ prrrrrrr zwZZZZ prrrrrr zwZZZZZ". Call "st" or "tzi".
Habitat. Inhabits cultivated areas, including edge of agricultural fields, pastures, villages and edges of towns; also shrubby hillsides and grasslands adjacent to thickets or scrub. Generally occurs at 1000–3700 m; up to 4650 m in Santa Marta Mts (N Colombia); also down to sea-level in Peru (Lima).
Food and Feeding. Seeds, with apparent liking for seeds of composites; also eats berries and insects. Forages on ground and in low vegetation; often perches on grass or weed stems to extract seeds while still on stalk. In pairs and in small groups of up to 20 individuals; often in mixed flocks with other seed-eating species.
Breeding. Fledglings found in May (Moquegua) and Jun (Amazonas) in Peru and in Sept in Colombia (Boyacá); breeding appears to take place in Mar–May (after summer rains) in S Peru and N Chile. Nest a cup made from vegetable fibres, lining of hair and wool. Clutch in Argentina 3 eggs, pale greenish with brown and violet markings, these largely concentrated at wide end; in Colombia 2 eggs, bluish with darker marking around wide end. No other information.
Movements. Largely resident. In C Argentina evidence of some downslope movements in winter, some reaching W Buenos Aires during non-breeding season.
Status and Conservation. Not globally threatened. Fairly common to common, and locally abundant. Has large range, high abundance, and no evidence of any significant population declines.
Bibliography. Armani (1985), Bond (1951a), Canevari *et al.* (1991), Chapman (1915, 1924), Dickerman (1986), Fjeldså & Krabbe (1990), Johnson & Goodall (1967), Marone (1992a), Maugeri (2006), Narosky *et al.* (1984), Restall *et al.* (2006), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), Stiles *et al.* (2000).

296. Plain-colored Seedeater

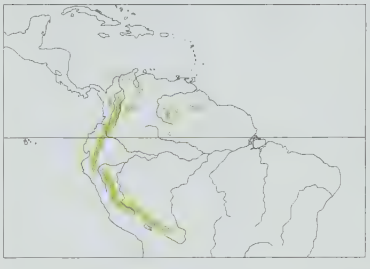
Catamenia inornata

French: Cataménie terne **German**: Schlichtcatamenie **Spanish**: Semillero Sencillo
Other common names: Plain Seedeater

Taxonomy. *Linaria inornata* Lafresnaye, 1847, Bolivia.
Molecular data suggest that genus is part of a clade which includes *Haplospiza*, as well as *Phrygilus unicolor* and *Phrygilus plebejus* (but not other members of latter genus). Four subspecies recognized.
Subspecies and Distribution.
C. i. mucuchiesi Phelps, Sr & Gilliard, 1941 – *páramos* of Mérida, in W Venezuela.
C. i. minor Berlepsch, 1885 – W Venezuela (Táchira) S through Andes of Colombia (E & C ranges) and Ecuador to C Peru (Junín).
C. i. inornata (Lafresnaye, 1847) – Andes of SW Peru (Cuzco and Puno) and extreme N Chile (N Tarapacá) E to C Bolivia and NW Argentina (S to C Mendoza).
C. i. cordobensis Nores & Yzurieta, 1983 – NC Argentina (Córdoba).

Descriptive notes. 13·5–14·5 cm; 12·3–14·5 g. A small finch with conical bill as long as it is deep, but with only very slightly rounded culmen. Male nominate race has head grey, crown slightly darker and indistinctly streaked, grey neck nearly unstreaked, darker grey mantle and back clearly and narrowly streaked; rump unstreaked grey; tail feathers blackish-brown with grey fringes; upperwing blackish-brown, indistinct greyish fringes on coverts and flight-feathers; grey below, paler on throat, darkest on breast and flanks, with belly paler buffy grey, crissum chestnut; iris dark; bill salmon-pink, browner in non-breeding period; legs pinkish to dusky, usually duller on feet. Female is brown above with distinct blackish-brown streaking, densest on crown and back, least dense on hindneck and rump; ground colour of back slightly paler brown than rest of upperparts; entirely buff below, dense streaking on throat, breast, flanks and crissum, belly unstreaked; bill often brownish. Juvenile has brown crown with conspicuous dark shaft streaks, back tawny-olive with broad dark streaks, rump buffy brown, throat and breast whitish-grey, streaked dark on breast, flanks and undertail-coverts, bill all dark; male appears to go through two plumages after juvenile before reaching adult, becoming less streaked and greyer with age, first immature still noticeably streaked on crown and back, and rump brown, second immature stage like adult, but olive wash on crown and back, buff wash on underparts, weakly streaked on back (crown appears streaked only in worn plumage); young female like adult, but even browner above and underparts paler, two post-juvenile stages before adulthood but differences more subtle than in male, with age essentially more greyish (less brownish) and streaking reduced. Race *minor* is smaller than nominate, has smaller and finer bill; *mucuchiesi* is similar to previous, but above darker, more dark bluish-slate (less dull greenish-grey), streaking on back darker, blackish, throat and chest deeper grey, belly paler, also has heavier and more conical bill than others; *cordobensis* is slightly smaller than nominate, male paler grey, especially on underparts, with cinnamon-buff tinge on flanks, female more yellowish-brown and more evenly streaked on head. Voice. Song, from top of low bush, geographically and individually variable, the most noticeable part a short and buzzy musical trill. Often 2–5 very soft and short musical notes (not audible from any great distance) followed by 2–6 slow buzzy trills, varying in speed and pitch, total duration 3–6 seconds; often contains trills that ascend or descend in a sequence, and interspersed with sweeter descending whistle, "prrrr trrrr CHHRRR tweeew prrrr CHRRRR tweeew..." or "trrrrr PRRR tzeew PRRRR tzeew trrrr CHRRRR". Call a fine "zee" and a lower "tchip".
Habitat. Open highland grasslands; also *Espeletia páramo* and *puna* areas with grass; also pastures with shrubs or adjacent small trees, *Polylepis* forest edge, and short *Polylepis* scrub. Generally on slopes, particularly shrubby slopes, tending to occupy dry sites rather than humid ones. At 2600–4400 m.
Food and Feeding. Seeds. Forages on ground; also feeds heavily on *Espeletia* seeds by perching on stems and feeding from exposed seed clusters. In pairs and small groups; in non-breeding season in larger flocks, sometimes mixed with *Phrygilus* species or other highland granivores.
Breeding. Eggs and fledglings in Feb in N Argentina (Jujuy); possibly breeds throughout year in Colombia, where males in breeding condition in Jan–Feb (in E Cauca), Jul–Aug (Santander) and Aug–Sept (Cundinamarca and Boyacá). No other information.
Movements. Apparently resident; some nomadic movements in *páramo* of Venezuela, depending on seed crops.
Status and Conservation. Not globally threatened. Uncommon to fairly common; more local in Venezuela. Reported from extreme N Chile, but no substantiated evidence of its occurrence there. Has large range, within which no evidence of any significant population declines.
Bibliography. Armani (1985), Bond (1951a), Dickerman (1986), Fjeldså & Krabbe (1990), Hilty (2003), Restall *et al.* (2006), Ridgely & Tudor (1989), Salvador & Narosky (1984).

297. Paramo Seedeater



Catamenia homochroa

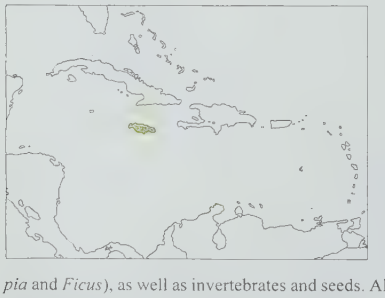
French: Cataménie du paramo **Spanish**: Semillero Paramero
German: Schlankschnabelcatamenie
Other common names: Colombian/Santa Marta Seedeater (*oreophila*); Tepui Seedeater (*duncani*)

Taxonomy. *Catamenia homochroa* P. L. Sclater, 1859, Matos, about 15 miles [c. 24 km] north of Riobamba, Ecuador.
Molecular data suggest that genus is part of a clade which includes *Haplospiza*, as well as *Phrygilus unicolor* and *Phrygilus plebejus* (but not other members of latter genus). Race *oreophila* often treated as a separate species. Differences in plumage, voice and ecology suggest that tepui race *duncani* may be a separate species, but more research needed. Also, birds in Sierra La Neblina, on

On following pages: 298. Orangequit (*Euneornis campestris*); 299. Cuban Grassquit (*Tiaris canorus*); 300. Yellow-faced Grassquit (*Tiaris olivaceus*); 301. Dull-colored Grassquit (*Tiaris obscurus*); 302. Black-faced Grassquit (*Tiaris bicolor*); 303. Sooty Grassquit (*Tiaris fuliginosus*).

S Venezuela–N Brazil border, have noticeably darker plumage than others, and may merit treatment as a separate race; study required. Three subspecies recognized.
Subspecies and Distribution.
C. h. oreophila Todd, 1913 – Santa Marta Mts, in N Colombia.
C. h. homochroa P. L. Sclater, 1859 – Sierra de Perijá (Colombia–Venezuela border), and Andes of W Venezuela (Mérida) and Colombia S to Peru and NW Bolivia (La Paz and Cochabamba).
C. h. duncani (C. Chubb, 1921) – tepui highlands of Venezuela and adjacent N Brazil (extreme N Amazonas).

Descriptive notes. 13·5 cm; 12·2–14·4 g. A small seedeater with longish conical bill longer than it is deep, with only very slightly rounded culmen. Male nominate race is entirely dark grey, except for dark rufous crissum and blacker face, and pencil-thin darker streaks on back; in fresh plumage, a warmer brownish wash on flanks; iris dark; bill bright to pale yellow-pink, sometimes ivory-pink (colour perhaps dependent on breeding state); legs dusky. Distinguished from *C. inornata* mainly by darker body plumage and pale and longer bill. Female is olive-brown above, streaked darker on crown to back, with lower back and rump largely unstreaked; face and underparts, including throat and breast, pale greyish, sometimes some fine dark streaking on breast and flanks, unstreaked crissum pale chestnut, becoming pale cinnamon on belly; pale pinkish bill with dark tip. Juvenile is like female, but darker-billed and strongly streaked throughout, including underparts and crissum; male appears to go through two post-juvenile plumages before adult, first immature still noticeably streaked on crown and back, with rump brown (like female, but more strongly streaked), second immature like adult male but olive wash on crown and back, buff wash on underparts, back weakly streaked (crown appears streaked only when plumage worn), young female ages in similar manner, but distinctions between first and second immatures less noticeable. Race *oreophila* is longer-tailed and shorter-billed than others, has brown wash on breast and is more uniformly plumaged overall and generally paler than nominate; *duncani* is similar to nominate, but lighter grey, back browner and with more noticeable dark streaking, tertials with wider brown edging (fresh plumage), flanks browner, bill more yellowish. Voice. Song in Peru a series of melancholy buzzy whistles, "dseeeeeee djúúúúúúúú-djúúúúúúú-djúúúúúú"; in Bolivia a high-pitched, electrical-sounding buzzy whistle that ascends slightly in pitch, "tzzzzzzzz"; *duncani* sings a low-pitched whistle. Contact call a doubled "ts-ip!", flight call "tsit-tsit".
Habitat. Moist shrubbery at edge of montane forest, elfin forest, cloudforest edge, also second growth, usually below tree-line and tends not to venture into open grassland; in Andes, presence of *Chusquea* bamboo in the area appears to be important. In tepuis, race *duncani* in more open habitats, often singing from exposed rocks, primarily in *Brocchinia* scrub. At 2500–3500 m; *duncani* 1600–2500 m.
Food and Feeding. Variety of seeds; in Andes primarily those of *Chusquea* bamboo (seeding of which is cyclic and very localized), whereas isolated tepuis race (*duncani*) appears not to be associated with bamboo-flowering. Forages on ground, also in vegetation; tends to keep under cover of vegetation, seldom foraging in open, exposed situations. Generally shy and retiring. In pairs and small groups; may forage with mixed-species flocks of tanagers and flowerpiercers (Thraupidae), sometimes also with congeners.
Breeding. Juveniles in Jul in Peru (Cuzco) and birds in breeding condition in Jul in Colombia (Perijá and E Antioquia). No other information.
Movements. Resident; may be somewhat nomadic, following seeding of *Chusquea* bamboo.
Status and Conservation. Not globally threatened. Rare to uncommon and local; can be fairly common in Colombia. Has large range, and no evidence of any significant population declines.
Bibliography. Armani (1985), Chubb (1921b), Dickerman (1986), Fjeldså & Krabbe (1990), Hilty (2003), Restall *et al.* (2006), Ridgely & Tudor (1989), Romero-Zambrano (1977), Willard *et al.* (1991).



Genus *EUNEORNIS* Fitzinger, 1856

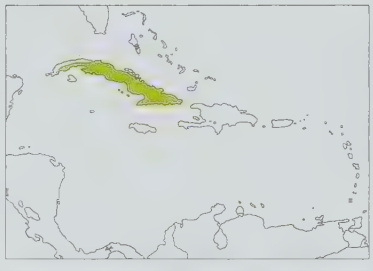
298. **Orangequit**

Euneornis campestris

French: Pique-orange de Jamaïque **German**: Braunlatz-Ammerfink **Spanish**: Semillero Azulillo

Taxonomy. *Motacilla campestris* Linnaeus, 1758, Jamaica.
Sometimes placed in tanager family (Thraupidae), with which perhaps has closer ancestral affinities; appears to be part of a clade which also includes several other Caribbean genera (*Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Monotypic.
Distribution. Jamaica.

Descriptive notes. 14 cm; 13·2–19·2 g. A small finch-like bird with slightly decurved bill. Male is almost entirely grey-blue (appearing dark in poor light), with orange-red throat; iris dark brown; bill and legs black. Female has crown and nape olive-grey, upperparts warmer and browner; dull greyish-white below, faintly streaked, flanks washed light buffish. Juvenile is like female. Voice. A thin, high-pitched "tseet", or occasionally "fi-sweee".
Habitat. Humid forest, also commonly in shade coffee plantations. Sea-level to 1500 m; commonest at middle elevations.
Food and Feeding. Nectar; also fruit (*Cecropia* and *Ficus*), as well as invertebrates and seeds. Also takes tree sap at holes drilled by sapsuckers (*Sphyrapicus*). Forages at low to medium heights. Generally singly and in pairs.
Breeding. Season Apr–Jun. Nest a moderately deep cup, usually uncovered, made from grass and plant fibres, built up to 6 m above ground in tree or shrub; abandoned nest of Jamaican Becard (*Pachyramphus niger*) occasionally used. Clutch 2–4 eggs, white with reddish-brown and grey-brown markings, these concentrated at wide end; incubation by female. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally common. No known threats.
Bibliography. Cruz (1974), Dunning (2008), Levy (1997), Mundle (2000), Raffaele *et al.* (1998), Ridgway (1901).



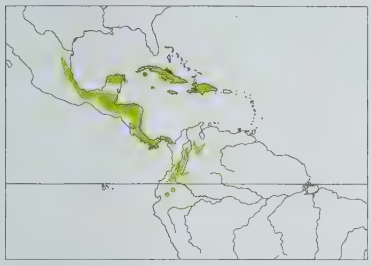
Genus *TIARIS* Swainson, 1827

299. **Cuban Grassquit**

Tiaris canorus

French: Cici petit-chanteur **German**: Kubagimpelfink **Spanish**: Semillero Canoro
Other common names: Melodious Grassquit

Taxonomy. *Loxia canora* J. F. Gmelin, 1789, Nova Espania; error = Cuba.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Molecular data suggest that genus as currently constituted is polyphyletic; further research required. Monotypic.
Distribution. Cuba.



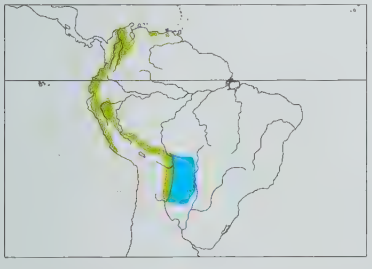
Descriptive notes. 11·5 cm; 6–9·5 g. Small and short-tailed, with distinctive plumage pattern. Male has black face and throat, contrasting broad yellow patch starting above eye, curving around rear ear-coverts and extending forward as broad collar to lower throat (collar often broken in centre); crown and upperparts, including upperwing and tail, greenish, crown often greyer, primaries edged yellowish; breast black, side of breast and rest of underparts olive-grey, paler posteriorly; iris dark brown; bill black; legs pinkish to flesh-coloured or dark. Female is similar to male, but duller, lacking black; face dark chestnut, collar paler yellow. Juvenile resembles female, but duller. Voice. Song a shrill "chiri-wichi-wichi, chi-wichi-wich" or "tsit-tsit-tilloi", characterized by buzzy and harmonic rich syllables, also a longer song characterized by many pure-toned syllables; short song probably primarily aggressive in function (increased in frequency in presence of other males), long song probably sexual in function (increased in presence of females). Partners also sing in duet against territorial rivals, or as greeting ceremonies between mates. Call a soft "chip" or high "tsit", often repeated.
Habitat. Primarily in semi-arid country, commonly near coast, also in open pines (*Pinus*), brushy areas, shade coffee and citrus plantations, and rural farmland with shrubbery. Sea-level to middle elevations.
Food and Feeding. Feeds on seeds and small fruits. Forages generally near the ground. Will leap upwards to reach seeds still on stem. Singly and in pairs; in flocks outside breeding season.
Breeding. Season Apr–Jun. Nest a large globular mass of woven dried grasses, lined with softer materials, entrance on side, placed low in spiny branches of tree. Clutch 2–3 eggs, pale greenish-white with lilac or brown spots, especially at large end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common in some parts of Cuba. Appears to be declining in some places close to human settlements.
Bibliography. Armani (1985), Baptista (1978), David & Gosselin (2002b), Dunning (2008), Garrido & Kirkconnell (2000), Grant, Grant & Petren (2000b), Llerena de Calgua (2006), Raffaele *et al.* (1998), Ridgway (1901), White *et al.* (2006).

300. **Yellow-faced Grassquit**

Tiaris olivaceus

French: Cici grand-chanteur **German**: Goldbrauen-Gimpelfink **Spanish**: Semillero Tomeguín
Other common names: Mexican Grassquit

Taxonomy. *Emberiza olivacea* Linnaeus, 1766, Dominica = Hispaniola.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Molecular data suggest that genus as currently constituted is polyphyletic; further research required. Proposed race *coryi* (described from Cayman Brac, in Cayman Is) is synonymized with nominate. Five subspecies recognized.
Subspecies and Distribution.
T. o. pusillus Swainson, 1827 – Atlantic slope of Mexico S locally through Central America to Colombia (W of E Andes, excluding Santa Marta region) and NW & E Ecuador, and W Venezuela (SW Mérida and Táchira).
T. o. intermedius (Ridgway, 1885) – Cozumel I (off Quintana Roo), in E Mexico.
T. o. ravidus Wetmore, 1957 – Coiba I (off S Veraguas), in W Panama.
T. o. olivaceus (Linnaeus, 1766) – Cuba, I of Pines, Cayman Is, Jamaica and Hispaniola.
T. o. bryanti (Ridgway, 1898) – Puerto Rico and neighbouring islands.
Descriptive notes. 9·3–11·5 cm; 6–10 g. Small and short-tailed. Male is olive above, including upperwing and tail; prominent deep orange-yellow supercilium from above lores to behind eye, pale yellow crescent below eye; face and breast blackish, distinctive orange-yellow patch on chin and throat; side of breast and rest of underparts light olive-grey; iris black; bill and legs dark. Female is like male, but dull greenish, without black markings; supercilium pale creamy, throat patch much paler. Juvenile resembles female, but greyer and duller. Race *bryanti* is similar to nominate, but is rather smaller, and much brighter olive-green above, more yellowish on underparts; *intermedius* is larger than nominate, with black on chest of male more extensive; *pusillus* is similar to previous, but male has black more extensive, sometimes with ear-covert region and crown black; *ravidus* is darker than last, black on male extending to nape and, below, to belly.



Voice. Song, delivered from a low perch, mostly during wet season (singing commences when rains begin), is a long weak, insect-like rapid high-pitched trill, "ti-ti-ti-ti" or "tsee-tsee-tsee-tsee" (c. 10 notes given per second). Call is a quiet "tick" or "tsit".
Habitat. Moist pastures, thickets, clearings, roadsides, and shrubby fields with scattered shrubs and trees, second growth and tall grass; usually found in scrub in grassy areas. Lowlands to 2000 m.
Food and Feeding. Feeds on seeds of grasses (*Paspalum*, *Panicum*), and sometimes takes insects and berries; also picks tiny white protein bodies from *Cecropia* trees. Forages sometimes on ground, but often while perched on grass stem and picking seeds from seedhead or heads of nearby grasses; when seeds scarce, will forage in trees in manner of New World warbler (Parulidae). In pairs and small groups; often in flocks with other seedeaters (e.g. *Volatinia*, *Sporophila*).
Breeding. Season Apr–Jan (most commonly May–Aug), Jan on Coiba I (race *ravidus*) and probably Mar in El Salvador; throughout year in Cuba, and in virtually all months in rest of West Indies. Monogamous. Male sings especially intensely when nesting, and courting male may sing while vibrating wings a few centimetres from female. Nest built by both sexes, a globular structure with side entrance, made from thickly woven dry grasses, lined with finer fibres, placed often low down, sometimes as high as 1·5 m, in grass clump or other low vegetation. Clutch 2–4 eggs (usually 2, rarely 4), dull white with blue cast, spotted with brown or lilac, especially at large end; chicks fed by both parents. No other information.
Movements. Generally sedentary. In S USA, nominate race casual in Florida and *pusillus* vagrant in S Texas, indicating some short, dispersive movements.
Status and Conservation. Not globally threatened. Very common in appropriate habitat. Has wide range, in which no significant threats identified.
Bibliography. 301. **Dull-colored Grassquit**

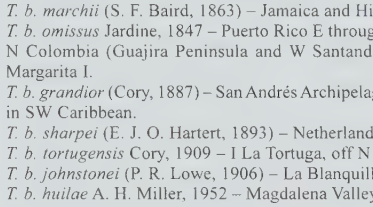
Tiaris obscurus

French: Cici obscur **German**: Braungimpelfink **Spanish**: Semillero Oscuro
Other common names: Dull-colored Seedeater

Taxonomy. *Emberiza obscura* d'Orbigny and Lafresnaye, 1837, Chiquitos, Bolivia.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Molecular data suggest that genus as currently constituted is polyphyletic; further research required. This species was previously included in genus in *Sporophila*, but skeletal features, nest type, song and molecular data indicate that it is better placed in present genus, and that it is sister to *T. fuliginosus*. Taxonomy complex: a detailed study of geographical variation of this species identified six diagnosable populations, each of which could be considered a race; of the currently recognized races, however, *pacificus* and *haplochroma* correspond to two of the six aforementioned populations, while nominate and *pauper* incorporate the remaining four. The six identified populations are: those in range of *haplochroma* (as listed below); population from extreme S Colombia and Ecuador (currently part of *pauper*); birds of dry N valleys of Peru, in valleys of R Marañón and R Huallaga (currently part of *pauper*); those in range of *pacificus* (as listed below); non-coastal regions in Peru, S to La Paz, in Bolivia (currently part of nominate); and E slope from N Bolivia S to N Argentina (currently part of nominate). Thorough review required. Pending full revision, four subspecies recognized.
Subspecies and Distribution.
T. o. haplochroma (Todd, 1912) – mountains of N Colombia (Santa Marta) and N Venezuela (Carabobo E to Monagas), also Andes S to Colombia (S in Cauca Valley to S of Cauca Province).
T. o. pauper (Berlepsch & Taczanowski, 1884) – extreme S Colombia (Nariño) S on W slope of Andes to NW Peru (to La Libertad and Cajamarca) and on E slope in N Peru (S to San Martín and Loreto).
T. o. pacificus (Koepcke, 1963) – coastal plain and slope in Peru from Ancash S to Arequipa.
T. o. obscurus (d'Orbigny & Lafresnaye, 1837) – E slope of C Peru (from San Martin S, patchily, to Puno) and S through Andean slopes of Bolivia to NW Argentina (S to Tucumán); also, probably non-breeding, in E lowlands of Bolivia (Santa Cruz and Chuquisaca), W Paraguay and N Argentina (Chaco).



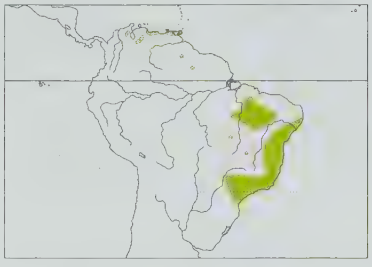
Descriptive notes. 10·5–11·5 cm; average 11·2 g. A small songbird, moderately long-tailed and small-headed, with short conical bill with relatively straight culmen. Nominate race (in extreme S of range) is very plain, brownish all over, paler on underparts; has very dull and narrow paler supercilium, darker eyeline, and pale crescents above and below eye; throat, breast and upper flanks more greyish-brown, a greyish wash sometimes extending to face; nominate geographically variable, in C to S Peru and adjacent Bolivia (La Paz) darker grey-brown on chest than those farther S, creating distinct contrast with pale belly, whereas populations from W slope of La Paz S to Argentina are pale like N Peruvian birds; iris dark brown; bill dark, yellowish-horn base of lower mandible, some variation in colour due to sex and breeding state; legs brownish. Sexes alike. Juvenile is similar to adult. Races differ in plumage coloration and bill colour: *haplochroma* is darker below than others, also more uniform, with no contrast between breast and belly, also the only race with entirely dark bill; *pauper* in N of range (extreme S Colombia and Ecuador) has bicoloured bill with pale lower mandible, paler brown breast with pale cream belly, contrasting buffier flanks, in S (N Peru from W slope of Andes, also Marañón and Huallaga Valleys) greyish on breast, with flanks pale like belly, some with whitish throat; *pacificus* is large and pale, in plumage resembles N Peruvian populations of previous. Voice. Song buzzy and explosive, "zeetig, zeezeezig", in Peru also described as similar to that of *Volatinia jacarina* but longer, more complex and more musical; little geographical variation in songs, all being quite clearly identifiable as of present species. Call a high-pitched "ti".
Habitat. Edge habitats, including edge of open forest, shrubby clearings and roadside thickets, also gardens, dry scrub; also in Lomas vegetation in coastal Peru (race *pacificus*). At 500–2100 m.
Food and Feeding. Seeds; often takes seeds of grasses, particularly *Panicum*. Usually forages on ground or by bending down grass-heads or other seedheads, often within cover of understorey. Found singly and in pairs, sometimes in small groups.
Breeding. Season Jan–Feb in Bolivia and Argentina. Nest domed, with rounded side entrance, constructed from vegetable fibres, small overhang over entrance, placed in upright triple fork of branch usually less than 3 m from ground in small tree or bush. Clutch 3–4 eggs, whitish with evenly distributed pale brown and dark brown speckling. No other information.
Movements. Resident in most of range. Lowland populations in E Bolivia appear to be present largely in non-breeding season; these presumed migrants from higher elevations in Bolivia, indicating an E–W migratory movement in extreme S of species' range. Recorded in SW Brazil (Mato Grosso).
Status and Conservation. Not globally threatened. Uncommon to locally common; rare in much of Peru. Has large range, within which no evidence of any large-scale population decline. In Venezuela, this species area of distribution appears to have become smaller as a result of to urbanization and development; in Ecuador, on other hand, it is thought to be expanding.
Bibliography. Armani (1985), Bates (1997, 2006), David & Gosselin (2002b), Grant, Grant & Petren (2000b), Koepcke & Koepcke (1961), Lijtmaer *et al.* (2004), Ouellet (1992), de la Peña (1987), Ridgely & Greenfield (2001a), Ridgely & Tudor (1989), Schulenberg *et al.* (2007), de Vasconcelos *et al.* (2008), Webster & Webster (1999).

302. **Black-faced Grassquit**

Tiaris bicolor

French: Cici verdinère **German**: Jamaikagimpelfink **Spanish**: Semillero Biocolor
Other common names: Black Sparrow, Grass Bird (Jamaica)

Taxonomy. *Fringilla bicolor* Linnaeus, 1766, America = Bahama Islands.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Molecular data suggest that genus as currently constituted is polyphyletic; further research required. Eight subspecies recognized.
Subspecies and Distribution.
T. b. bicolor (Linnaeus, 1766) – Bahama Is; Cayo Tío Pepe, NW of Isabela de Sagua, off N Cuba.
T. b. marchii (S. F. Baird, 1863) – Jamaica and Hispaniola, including nearby small islands.
T. b. omissus Jardine, 1847 – Puerto Rico E through Lesser Antilles to Tobago, and mainland from N Colombia (Guajira Peninsula and W Santander) E through coastal Venezuela to Sucre and Margarita I.
T. b. grandior (Cory, 1887) – San Andrés Archipelago (Providencia, Santa Catalina and San Andrés), in SW Caribbean.
T. b. sharpei (E. J. O. Hartert, 1893) – Netherlands Antilles (Aruba, Curaçao and Bonaire).
T. b. tortugensis Cory, 1909 – I La Tortuga, off N Venezuela.
T. b. johnstonei (P. R. Lowe, 1906) – La Blanquilla and Los Hermanos, off N Venezuela.
T. b. huilae A. H. Miller, 1952 – Magdalena Valley, in C Colombia.



Descriptive notes. 10·2–11·5 cm; 7–11·6 g. Small, relatively short-tailed emberizid. Male nominate race has black head, throat and most of underparts, with dark greenish flanks posteriorly; upperparts, including upperwing and tail, greenish; iris dark; bill black, gape becoming vivid pink during breeding season; legs flesh-coloured. Female is drab olive-green, somewhat browner or greyer below; dark upper mandible and paler lower mandible, bare parts otherwise much as on male. Juvenile is like female. Races differ mainly in size and plumage coloration: *omissus* is like nominate, but smaller; *marchii* is similar to previous, but male has black on underparts confined to anterior half; *grandior* is like *omissus*, but much larger and brighter olive-green above; *huilae* is paler brownish-olive above, with paler greyish flanks; *johnstonei* is blackest race, with upperparts, wings and tail brighter olive-green than nominate; *sharpei* is similar, but paler; *tortugensis* is paler still than last, greyish-olive above. Voice. Song an emphatic buzz, "tse-tsee-tsee-tsizzle-tsizzle", or a weak, buzzing series, "dik-zeezeezee" or "tzit-tzweeee". Call note a soft "tsip".
Habitat. Open, dry areas of acacia (*Acacia*) and cactus scrub with grasses and shrubs in forest clearings, along roads, urban areas, and plantations and gardens; in Netherlands Antilles occurs in manchineel (*Hippomane mancinella*) bushes and mangroves; on Curaçao, present even high in the Sint Christoffel Hills. Sea-level to 860 m.
Food and Feeding. Feeds almost exclusively on seeds; in Netherlands Antilles also on fruit (or possibly seeds) of large candle cactus (*Lemaireocereus*). Forages generally near ground. Singly and in pairs; often found in small groups. May roost communally in large numbers.
Breeding. Breeds throughout year in West Indies, Apr–Jun in Cuba; in rainy season, Jun–Jan, in Trinidad. Nests in small colonies or loose groups. Male sometimes performs aerial song display, rapidly vibrating wings and drifting downwards. Nest a globular mass of grasses with entrance on side or bottom, placed on ground among *Opuntia* cacti or up to 2·5 m up in small bush. Clutch 2–4 eggs, dull white, marked with pale reddish-brown at large end. No other information.
Movements. Resident. Some limited dispersal; vagrant in SE USA (S Florida; fewer than ten records), apparently involving nominate race from Bahamas.
Status and Conservation. Not globally threatened. Often common in appropriate habitat. Fairly common in Colombia and Venezuela; very rare in Cuba, where found only on Cayo Tío Pepe. Although still common, has apparently declined in number in Netherlands Antilles.
Bibliography. Armani (1985), Askins *et al.* (1987), Bates (1997), Boal *et al.* (2006), David & Gosselin (2002b), Dunning (2008), ffrench (1991), Garrido & Kirkconnell (2000), Goodwin (1959), Grant, Grant & Petren (2000b), Hilty (2003), Kale (1988), Keith *et al.* (2003), Raffaele *et al.* (1998), Reader, Morand-Ferron *et al.* (2002), Restall (1976, 2003), Ridgway (1901), Voous (1983), White *et al.* (2006).

303. **Sooty Grassquit**

Tiaris fuliginosus

French: Cici fuligineux **German**: Schwarzbrust-Gimpelfink **Spanish**: Semillero Fuliginoso

Taxonomy. *Fringilla fuliginosa* Wied, 1830, Camamú, Bahia, Brazil.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Molecular data suggest that genus as currently constituted is polyphyletic; further research required. Birds from Sierra de Perijá (W Venezuela) described as race *zuliae* and birds from Trinidad as *fumosus*, but both considered undiagnosable, as mensural and plumage characteristics variable throughout range of species. Monotypic.
Distribution. W & N Venezuela (Sierra de Perijá, N end of E slope of Andes, and coastal mountains from E Falcón and Carabobo E to Sucre; also Cerro Roraima, in E Bolívar); Trinidad; S Guyana; and E Brazil (Maranhão and Ceará to NE Goiás and Piauí; Pernambuco S to São Paulo) and extreme NE Argentina (Misiones).
Descriptive notes. 10–11·4 cm; 11–16 g (Trinidad). Small, all-dark emberizid. Male is sooty blackish, back with olive tinge; iris dark; bill dark, gape yellowish to orange-red; legs dark. Female is brown, darker above than below; richer-toned than *T. obscura*, and with yellowish gape and mostly dark bill. Juvenile is like female; first-year male similar to adult, but paler in colour, with greyish tones on head. Voice. Song "ezz'u'da'leé", like that of *T. bicolor*, but shorter and thin. Call "chee".
Habitat. Moist to humid forest edges, grassy areas, also regenerating burnt areas; in second growth and forest edges in Trinidad. Sea-level to 600 m in Trinidad; 800–2300 m in Venezuela.

Food and Feeding. A specialist on seeding bamboo (*Guadua* and *Chusquea*, possibly also *Merostachys*); forages on seedheads still attached to plant. Also takes seeds of grasses and some fruit. Singly and in pairs; in small flocks of up to c. 40 individuals outside breeding season, when sometimes roosts communally.
Breeding. Season Jul–Dec (and occasionally May) in Trinidad and Aug in NE Argentina; timing of breeding may be correlated to abundance of bamboo seed, and season may shift depending on local conditions. Nest a flimsy ball with side entrance, made from grasses and rootlets, lined with finer fibres, placed on stump, on ground or up to 10 m up in fork of small tree. Clutch 2–3 eggs, occasionally 4, white with brown markings; young fed by both parents. No other information.
Movements. Non-migratory, but eruptive and nomadic; wanders into regenerating burnt areas, also into areas of seeding bamboo. On Trinidad moves to higher elevations in wet season.
Status and Conservation. Not globally threatened. Status not well known; apparently fairly common. Eruptive behaviour makes true status in many areas difficult to assess. Only one confirmed record in Colombia, one in Bolivia, and one in Paraguay; isolated records in other parts of Brazil, e.g. Mato Grosso and Paraná. Some earlier reports of this species in e.g. Colombia apparently involved misidentified *T. obscurus*.
Bibliography. Genus *LOXIPASSER* H. Bryant, 1866

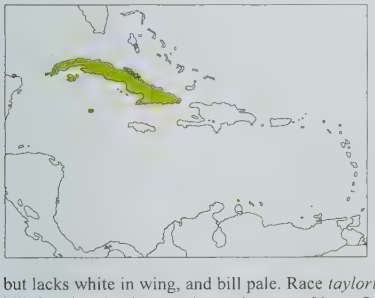
304. Yellow-shouldered Grassquit

Loxipasser anoxanthus

French: Pèrenoir mantelé **German**: Goldbug-Gimpelfink **Spanish**: Semillero Jamaicano
Other common names: Yellow-backed Grassquit/Finch/Grass Bird, Yellow-shouldered Finch

Taxonomy. *Spermophila anoxantha* Gosse, 1847, Mount Edgecumbe, Jamaica.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Melopyrrha*, *Loxigilla*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Monotypic.
Distribution. Jamaica.

Descriptive notes. 10·2–11·5 cm; 10·5–12·5 g. Very small, with moderately short tail and large head, bill thick and with strongly rounded culmen. Male has black on head and underparts to belly, lower belly and flanks greenish, contrasting rusty crissum; above, black extends to nape and lower neck, then strongly contrasts with grass-green mantle and back to tail; upperwing greenish, contrasting bright yellow shoulder; iris dark; bill and legs black. Female has head and breast grey with slight green wash; entire upperparts greenish with yellow wash, greenish wing strongly marked with yellow on shoulder; underparts below breast greyish-green, pale rusty crissum; bill horn-coloured, legs blackish. Juvenile is like female, but with reduced yellow at bend of wing. Voice. Song consists of 5 descending notes, with an almost echo-like quality.
Habitat. Edges of forest, including montane evergreen forest; woodlands, and gardens near wooded areas. Sea-level to 1800 m.
Food and Feeding. Seeds and fruits, probably also insects. Forages low in bushes and in trees. In small groups, presumably pairs and family groups.
Breeding. Season Mar–Sept, egg-laying recorded Mar–Jul. Nest a finely woven dome of grass and down, with side entrance, built in tree or bush, or concealed among epiphytes. Clutch 3–4 eggs, white with reddish or dull brown speckles and spots, these sometimes concentrated at broad end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common; reasonably widespread within its very small global range. No known threats.
Bibliography. Armani (1985), Douglas & Levy (1996), Dunning (2008), Hughes (1992), Raffaele *et al.* (1998), Ridgway (1901).



Genus *MELOPYRRHA* Bonaparte, 1853

305. Cuban Bullfinch

Melopyrrha nigra

French: Pèrenoir négrito **German**: Schwarzgimpelfink **Spanish**: Semillero Negrito
Other common names: Black Bullfinch/Sparrow (*taylori*).

Taxonomy. *Loxia nigra* Linnaeus, 1758, Cuba.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Loxigilla*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Race *taylori* sometimes considered a separate species. Two subspecies recognized.
Subspecies and Distribution.
M. n. nigra (Linnaeus, 1758) – Cuba (including some larger cays in Sabana-Camagüey Archipelago, and Cayo Cantiles in Los Canarreos Archipelago) and I of Pines.
M. n. taylori E. J. O. Hartert, 1896 – Grand Cayman I.

Descriptive notes. 14–15 cm; male 9–18·4 g, female 10·2–18·3 (nominate), 14·5–18·5 g (*taylori*). Small, dark finch with curved bill and white band on edge of wing. Male nominate race is black with blue or violet-blue gloss; alula, part of primary coverts, edging of outer web of one or more primaries white, greater portion of inner webs of secondaries and variable amount of inner webs of primaries (except outermost) white, underwing-coverts and axillaries also white; iris black; bill black; legs dark brownish. Female is like male, but black duller or dark slate in colour, paler on belly; bill black or dark slate. Juvenile is like female, but lacks white in wing, and bill pale. Race *taylori* is larger than nominate, with much more hefty bill, female paler than nominate, slate-grey. Voice. Song a thin melodious trill that ascends or descends in pitch, "ti ti ti ti-si-dddiiiyyy-sssiii". Call a buzzing "chip" or "chi-dip", or thin "tsee".
Habitat. Tropical evergreen forest, pine (*Pinus*) forests, brushy areas, including brush under pines, secondary forest; also mangroves. Sea-level to 900 m.
Food and Feeding. Feeds on insects, seeds and fruit. Forages in canopy, as well as near ground. Often in small flocks; sometimes in mixed-species foraging flocks.
Breeding. Season Mar–Jul. Nest a large spherical bulky mass with entrance at side, made from dried leaves, grass hairs, rootlets and feathers, built close to ground among bushes or twigs or placed low in spiny branches of trees; in one study, all nests found were built with materials from species of fern in genus *Lygodium*. Clutch 3–5 eggs, pale greenish-white, with reddish-brown and lilac spots concentrated at large end. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Common resident throughout Cuba and I of Pines; common on Grand Cayman I.
Bibliography. Armani (1985), Dunning (2008), Gálvez Aguilera *et al.* (1999), Garrido & Kirkconnell (2000), Michaelis (1978), Raffaele *et al.* (1998), Ridgway (1901), Sánchez *et al.* (2003).

Genus *LOXIGILLA* Lesson, 1831

306. Puerto Rican Bullfinch

Loxigilla portoricensis

French: Pèrenoir de Porto Rico **Spanish**: Semillero Puertorriqueño
German: Rotkopf-Gimpelfink
Other common names: Puerto Rican Grosbeak; Mountain Blacksmith (*grandis*)

Taxonomy. *Loxia portoricensis* Daudin, 1800, Puerto Rico.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Lesser Antilles race *grandis*, sometimes considered a separate species, is extinct. One extant subspecies recognized.
Subspecies and Distribution.
L. p. portoricensis (Daudin, 1800) – Puerto Rico.

Descriptive notes. 16·5–19 cm; male 26·7–44·8 g, female 23·4–45·5 g. Male has forecrown and side of crown, chin, throat, chest and undertail-coverts orange-red; rest of plumage black; iris dark brown; bill and legs dusky. Female is similar to male, but black less intense. Juvenile is deep olive-brown or olive, with undertail-coverts orange-rufous. Extinct race *grandis* was substantially larger and thicker-billed than nominate, with rufous darker and, on throat, more restricted. Voice. Song is a series of 2–10 rising whistles, followed by a buzz, or a loud "coochi, coochi, choochi". Call "check".
Habitat. Montane evergreen forest, tropical lowland evergreen forest, tropical deciduous forest, secondary forest, dry coastal thickets, occasionally mangrove forest. Sea-level to 1000 m.
Food and Feeding. Broad diet. Feeds mostly on fruits and seeds, also on flower parts; snails (Gastropoda) and insects also taken. In one study, found to forage on 41 species of plant, taking mainly fruits and seeds, and lesser amounts of shoots and flowers; Melastomataceae accounted for 43% of fruit consumed. Mainly arboreal, but may also drop to ground to forage. In forests feeds within middle strata of trees, searching outer branches more than inner ones.
Breeding. Season mainly Feb–Jun. Nest typically a spherical structure of twigs and leaves, with side entrance (rarely a cup, perhaps when structure not yet finished), placed on tree branch or in tree cavity, in shrub or in grass clump. Clutch usually 3 eggs, dull greenish with dark spots. No other information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Race *grandis* extinct. Nominate race very common in woodlands of Puerto Rico, particularly in heavy forests of mountains. One of this species' congeners, *L. noctis*, has recently become established on St John (in Virgin Is); if it colonizes Puerto Rico, it may compete with present species. Race *grandis* was formerly resident on St Christopher (St Kitts), in N Lesser Antilles, but not reported since 1920s; the possibility that it might survive in highlands of Mt Misery seems very remote, and this race is considered extinct. Cause of its demise was almost certainly damage to and loss of its limited environment, as a result of hurricanes.
Bibliography. Armani (1985), Dunning (2008), Garrido & Wiley (2003), Olson (1984), Pérez-Rivera (1994), Raffaele (1977, 1989), Raffaele *et al.* (1998), Ridgway (1901).

307. Greater Antillean Bullfinch

Loxigilla violacea

French: Pèrenoir petit-coq **German**: Rotsteiß-Gimpelfink **Spanish**: Semillero Prieto
Other common names: Jamaican Bullfinch (*ruficollis*)

Taxonomy. *Loxia violacea* Linnaeus, 1758, America = Bahamas.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Several races differ almost exclusively on size, and validity questionable. Proposed race *parishi* (described from I à Vache) supposedly differs on smaller size, but measurements do not confirm this; birds of Beata (and previously those of Catalina) sometimes

On following pages: 308. Lesser Antillean Bullfinch (*Loxigilla noctis*); 309. Barbados Bullfinch (*Loxigilla barbadensis*); 310. St Lucia Black Finch (*Melanospiza richardsoni*); 311. Green Warbler-finch (*Certhidea olivacea*); 312. Grey Warbler-finch (*Certhidea fusca*); 313. Vegetarian Finch (*Platyspiza crassirostris*); 314. Cocos Finch (*Pinaroloxias inornata*).

allotted to this race. Birds of Gonâve and Saona sometimes placed in *maurella*. Five subspecies tentatively recognized.

Subspecies and Distribution.

L. v. violacea (Linnaeus, 1758) – most of the larger islands in Bahamas.
L. v. ofella Buden, 1986 – Middle and East Caicos Is (S Bahamas).
L. v. affinis (Ridgway, 1898) – Hispaniola, and offshore islands of Gonâve, à Vache, Beata, Catalina and Saona.
L. v. maurella Wetmore, 1929 – Tortue I (off NW Hispaniola).
L. v. ruficollis (J. F. Gmelin, 1789) – Jamaica.

Descriptive notes. 13·2–17·5 cm; 18–32·4 g. Sturdy, with thick bill. Male nominate race is black, with red-orange short supercilium, throat and undertail-coverts; iris dark; bill dark grey; legs dusky. Female is similar to male, but duller black, more slaty, especially on upperparts. Juvenile is like female, but less greyish, upperparts brown, reddish-orange markings as on adults, but reduced in size on throat. Race *ofella* resembles nominate, but smaller; *affinis* smaller and glossier than nominate; *maurella* is like last, but larger; *ruficollis* is larger than nominate, duller and greyer, with paler rufous on throat and supercilium. Voice. Song a repeated trill of insect-like notes, "t'zeet t'zeet t'seet t'seet seet seet seet". Call a thin "spit".

Habitat. Dense thickets and undergrowth in habitats ranging from dry coastal scrub to wet mountain forest, including pine (*Pinus*) woods and gardens. Sea-level to 2000 m.

Food and Feeding. Feeds mostly on fruits and seeds, also on flower parts and snails (Gastropoda). Tends to keep in dense vegetation; probably feeds on or near ground.

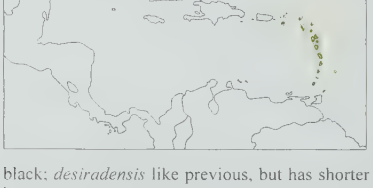
Breeding. Egg-laying Mar–Jun. Nest sometimes a cup, usually a spherical structure with side entrance, made from twigs and leaves, lined with bromeliads, fine pieces of bark and other fine material, placed on tree branch or in tree cavity, in shrub or in grass clump. Clutch 3–4 eggs, very pale bluish-white with thin red-brown and yellow-brown marks, these concentrated at wide end. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Common on large islands of Bahamas; similarly common in Jamaica and Hispaniola. Current status of populations on smaller islands not known.

Bibliography. Armani (1985), Bond (1943), Buden (1986), Conklin (1970), Dunning (2008), Keith *et al.* (2003), Raffaele *et al.* (1998), Ridgway (1901), Wetmore & Lincoln (1933).

308. **Lesser Antillean Bullfinch**



Loxigilla noctis

French: Pèrenoir rougegorge **German**: Bartgimpelfink **Spanish**: Semillero Gorjirrojo
Other common names: West Indian Robin; Red-throat See-see (*grenadensis*)

Taxonomy. *Fringilla noctis* Linnaeus, 1766, Martinique.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Formerly considered conspecific with *L. barbadensis*. Eight subspecies recognized.

Subspecies and Distribution.

L. n. ridgwayi (Cory, 1892) – St John (Virgin Is), St Croix (US Virgin Is) and N Lesser Antilles (Anguilla, St Martin, Barbuda and Antigua).
L. n. coryi (Ridgway, 1898) – Saba, St Eustatius, St Christopher (St Kitts), Nevis and Montserrat, in NW Lesser Antilles.
L. n. desiradensis Danforth, 1937 – Désirade, in NC Lesser Antilles.
L. n. dominicana (Ridgway, 1898) – Guadeloupe, Is des Saintes, Marie Galante and Dominica, in NC Lesser Antilles.
L. n. noctis (Linnaeus, 1766) – Martinique, in SC Lesser Antilles.
L. n. sclateri J. A. Allen, 1880 – St Lucia, in SC Lesser Antilles.
L. n. crissalis (Ridgway, 1898) – St Vincent, in S Lesser Antilles.
L. n. grenadensis (Cory, 1892) – Grenada, in S Lesser Antilles.

Descriptive notes. 14–15·5 cm; 13·1–23·4 g. Male nominate race is black, with small red patch above and in front of eye, and red on throat; iris dark; bill black; legs dusky. Female is brown, with slightly rusty upperwing-coverts and uppertail-coverts, greyer below; bill brown, paler below. Juvenile resembles female. Race *sclateri* is similar to nominate, but smaller; *crissalis* has rufous throat patch more extensive, also undertail-coverts extensively chestnut-rufous; *grenadensis* is like previous, but throat patch more restricted, undertail-coverts partly black; *dominicana* has rufous undertail-coverts, sometimes mixed with black; *desiradensis* like previous, but has shorter wing and tarsus; *ridgwayi* is like *dominicana*, but smaller, with proportionately large bill and feet, also plumage greyish-black (not black), underparts slate-grey; *coryi* is like last, but slightly darker. Voice. Song a crisp trill of 5–10 "tseep" notes usually ending with sharp "chuck" or a buzz. Call "check".

Habitat. Tropical evergreen forest, deciduous woodlands, second growth, gardens, and forest understorey; sometimes in dry areas and mangrove swamps. Sea-level to 900 m.

Food and Feeding. Diet varied; nectar, also fruits and seeds, as well as arthropods. Known to rob flowers of nectar; reaches nectar by biting a small hole at base of calyx. Uses foot to secure fruits as it eats them; essentially steps on fruit against a branch while it feeds from it. Forages mainly up in trees; occasionally descends closer to ground. Sometimes enters dwellings and other buildings in search of food scraps.

Breeding. Egg-laying Feb–Aug; Jan–Feb in Virgin Is. Nest domed, with opening at side, tends to be below 3 m, but varies (c. 1–5 m). Clutch 2–4 eggs, white with fine red specks, these mainly at wide end. No other information.

Movements. Mainly sedentary. Possibly some dispersive movements.

Status and Conservation. Not globally threatened. Common in Lesser Antilles; fairly common and widespread on St John; local breeder on St Croix. Arrived c. 1960 in Virgin Is, where found primarily in dry scrub; considered likely to expand its range to nearby islands.

Bibliography. Armani (1985), Askins *et al.* (1987), Bond (1939), Buckley & Buckley (2004), Dunning (2008), Greenlaw (1990), Prys-Jones (1982), Raffaele (1989), Raffaele & Roby (1977), Raffaele *et al.* (1998), Ridgway (1901).

309. **Barbados Bullfinch**

Loxigilla barbadensis

French: Pèrenoir de Barbade **German**: Barbadosgimpelfink **Spanish**: Semillero de Barbados

Taxonomy. *Loxigilla barbadensis* Cory, 1886, Barbados.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Melanospiza*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Formerly considered conspecific with *L. noctis*. Monotypic.

Distribution. Barbados.

Descriptive notes. 15·5 cm; 13·2–18·1 g. A small, comparatively dull-coloured finch with relatively short and rounded bill slightly longer than it is deep, often upper mandible slightly longer than lower mandible. Has greyish-brown head, slightly browner on crown, unmarked brownish-grey upperparts, including upperwing and tail; back of neck and nape often slightly more greyish than back and crown; upperwing edged with cinnamon-brown on coverts and less so on flight-feathers; chin whitish, throat and most of underparts grey, lower belly and vent whitish, crissum pale cinnamon (some individuals have crissum creamy to whitish, perhaps immatures or perhaps dull females); iris dark; bill black; legs blackish. Sexes similar. Juvenile resembles adult. Voice. Song, from visible perch, edge of small tree, or even building, a repeated set of short sibilant whistles, "sip sip sip sip sip" or "tse tse tse tse tse".

Habitat. Open country, woodland, dry scrub, hotel lawns, villages, essentially any habitat having a mix of taller vegetation and shorter shrubs or grass.

Food and Feeding. Varied diet, including seeds (36%), flowers (29%), insects (20%) and fruit (10%). Forages from ground level to 12 m up; most often on ground, where it pecks for seeds. When higher up, may glean for insects; also mandibulates bases of flowers, or even takes nectar from them. Often observed in small feeding flocks with *Tiaris bicolor*, particularly during dry season.

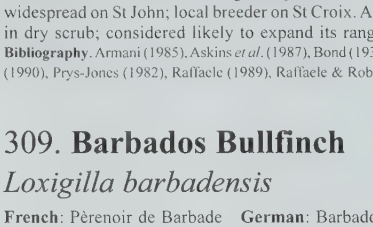
Breeding. Season Feb–Aug. Nest a domed structure with side entrance, of woven dry grass, usually placed less than 4 m from ground in small tree or shrub. Clutch 3–4 eggs. Male said to perform greater role in breeding, including bulk of nest-building, and greater effort in feeding female on nest and nestlings, than does *L. noctis*.

Movements. Resident.

Status and Conservation. Not globally threatened. Very common, and widespread within its tiny global range. Has adapted well to humans; can be found almost anywhere on Barbados, in nearly all habitats on the island, including urbanized areas, as well as agricultural sites; observed on front lawn of the international airport. No evidence of any major population decline.

Bibliography. Armani (1985), Buckley & Buckley (2004), Lovette, Seutin *et al.* (1999), McNair (1998b), Raffaele *et al.* (1998), Reader, Nover & Lefebvre (2002), Webster & Lefebvre (2000, 2001).

Genus *MELANOSPIZA* Ridgway, 1897



310. **St Lucia Black Finch**

Melanospiza richardsoni

French: Moisson pied-blanc **German**: Blassfuß-Gimpelfink **Spanish**: Semillero de Santa Lucía

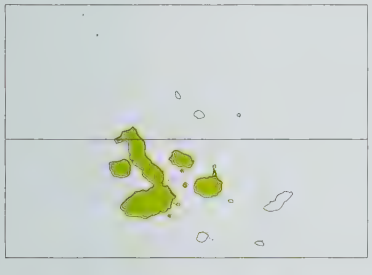
Taxonomy. *Loxigilla richardsoni* Cory, 1886, mountains of Santa Lucia, Lesser Antilles.
Genus may belong in tanager family (Thraupidae); appears to be part of a clade which also includes several other Caribbean genera (*Euneornis*, *Loxipasser*, *Melopyrrha*, *Loxigilla*), *Tiaris* grassquits, Bananaquit (*Coereba flaveola*), and "Darwin's finches" (*Certhidea*, *Platyspiza*, *Pinaroloxias*, *Camarhynchus*, *Geospiza*). Monotypic.

Distribution. St Lucia, in SC Lesser Antilles.

Descriptive notes. 13–14; 18–23 g. A stocky, thickset pink-legged finch with thick and proportionately large bill, large legs and feet, and relatively short tail. Male is uniformly deep black; undersurface of primaries slate-coloured; iris black; bill black; legs pinkish. Female has greyish head, contrasting brown upperparts, including upperwing and tail; dull light brown below; bill greyish-horn to blackish, legs pink. Juvenile is like female. Voice. Song a high-pitched, loud and sibilant "tseéééééwww- swisiwis-tew", the initial whistle explosive and with an almost electric quality. Call a sharp "tiiip!".

Habitat. Tropical lowland evergreen forest and secondary forest, from sea-level to 950 m. Prefers forest with generally complex understorey, usually moister sites; therefore in mountains, rather than dry lowlands, for the most part.

Food and Feeding. No details of diet; presumably arthropods, fruits and seeds. Found primarily on ground, where it forages in leaf litter in dense understorey; also commonly perches within 1 m of ground. Often in pairs.



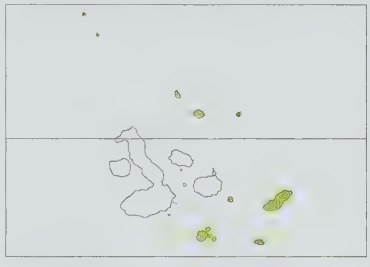
Breeding. Season Nov–Jun. Nest loosely constructed and spherical, with entrance at side, made from dried leaves, twigs, rootlets and ferns, placed c. 3 m above ground in small palm or shrub. Clutch 2 eggs, white with brownish-red spots and specks. No other information.
Movements. Sedentary.
Status and Conservation. ENDANGERED. Uncommon to rare, and local. Has tiny global range and very small population, estimated in range of 250–999 mature individuals; highest densities in moist montane forests. Thought to be in slow decline as a result of continuing habitat loss and degradation, coupled with effects of introduced predators. Main threat probably the clearing of undergrowth, especially in timber plantations, which makes such areas totally unsuitable for this species. Breeding success also hampered by introduced mongooses (Herpestinae) and rats (*Rattus*), which may prey on both nest contents and adults. This finch occurs in La Sorcière and Edmond Forest Reserves, and perhaps some other protected areas. Proposed conservation measures include surveys to ascertain the species' present distribution and population, and efforts to stop the clearing of undergrowth in wooded areas.
Bibliography. Anon. (2010c), Armani (1985), Bond (1929b), Butchart & Stattersfield (2004), Dunning (2008), Grant, Grant & Petren (2000b), Keith (1997), Raffaele *et al.* (1998), Ridgway (1901), Stattersfield & Capper (2000), Trail & Baptista (1988).

Genus *CERTHIDEA* Gould, 1837

311. Green Warbler-finch
Certhidea olivacea

French: Géospize olive **German**: Waldsänger-Darwinfink **Spanish**: Pinzón de Darwin Oliváceo
Other common names: Warbler-finch (when treated as conspecific with *C. fusca*)

Taxonomy. *Certhidea olivacea* Gould, 1837, Santiago (formerly James Island), Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Platyspiza*, *Camarhynchus* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Molecular data indicate that present genus is basal within the monophyletic lineage of Darwin's finches, and comprises two distinct and old lineages, the divergence of these two lineages pre-dating the radiation of all other Darwin's finches. Another study, including individuals from all 16 island populations of this genus, found that genetic and geographical distances are not correlated, and that genetic variation over a large area of the archipelago (the small peripheral islands) is very small; again, the data reveal two separate lineages, now treated as two species, namely present species and *C. fusca*. Monotypic.
Distribution. Islands of Fernandina (formerly Narborough), Isabela (Albermarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour) and Santa Cruz (Indefatigable), in Galapagos Is.

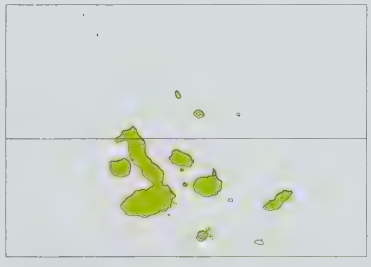


Descriptive notes. 10 cm; 8–12 g. A small Darwin's finch with characteristically long and pointed, parulid-like bill, and short and weak tail. Male is plain sandy brown above, with greyer head except for pale supercilium and foreface, unmarked brownish upperwing and tail; underparts variable, generally off-white, warmer buff on flanks, but some birds with throat and breast chestnut, on some restricted to mid-throat, on others extending to lores and clear down to breast and mid-flanks (differences perhaps related to age); iris dark; bill blackish when breeding, otherwise dull orange-yellow with dark culmen; legs blackish. Female is very like male, pale olive-brown on head and upperparts; upperwing sandy brown with indistinct wingbars, lower one often more obvious than upper one; off-white below, buffier wash on breast and flanks. Juvenile is similar to female. VOICE. Song, from tree or low bush, often high-pitched and includes buzzes, e.g. "piut-tze zzzzzzzzzzztip", duration c. 2 seconds, also a shorter song, e.g. "chzp-zhe chip" or "zhh-chip zhh-chip"; song parameters appear constrained by bill size, this small-billed species having relatively high trill rate, and relatively high frequency bandwidth. Similar to song of *C. fusca* (each will respond to playback of the other's song), but present species sings shorter songs with fewer repetitive notes.
Habitat. Can be found in most habitats and at most elevations on larger islands, but typically most common in humid highlands; only in very low abundance in dry lowlands, where perhaps only seasonal.
Food and Feeding. Food small insects and spiders (Araneae). Alone, or in loose groups, often with other finches.
Breeding. Nest built entirely by male, a sphere with entrance towards top and on side, made from dry grasses and other vegetation, often moss and lichen used. Clutch usually 4 eggs, whitish with pinkish or brown spots. No other information.
Movements. Resident; possibly some short seasonal movements.
Status and Conservation. Not globally threatened. Common and widespread through most of its range.
Bibliography. Armani (1985), Grant, B.R. & Grant (2002a), Grant, P.R. & Grant (2003), Lack (1947), McCarthy (2006), Petren, Grant, B.R. & Grant (1999a), Petren, Grant, P.R. *et al.* (2005), Podos (2001), Sulloway (1982a, 1982b), Swash & Still (2000), Tebbich *et al.* (2004), Tonnis *et al.* (2005).

312. Grey Warbler-finch
Certhidea fusca

French: Géospize gris **German**: Blindloedarwinfink **Spanish**: Pinzón de Darwin Gris
Other common names: Warbler-finch (when treated as conspecific with *C. olivacea*)

Taxonomy. *Certhidea fusca* P. L. Sclater and Salvin, 1870, Pinta (formerly Abington Island), Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Platyspiza*, *Camarhynchus* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Molecular data indicate that present genus is basal within the monophyletic lineage of Darwin's finches, and comprises two distinct and old lineages, the divergence of these two lineages pre-dating the radiation of all other Darwin's finches. Another study, including individuals from all 16 island populations of this genus, found that genetic and geographical distances are not correlated, and that genetic variation over a large area of the archipelago (the small peripheral islands) is very small; again, the data reveal two separate lineages, now treated as two species, namely present species and *C. olivacea*. Seven subspecies recognized.
Subspecies and Distribution.
C. f. becki Rothschild, 1898 – Darwin I (formerly Culpepper) and Wolf I (Wenman), in extreme NW Galapagos Is.
C. f. fusca P. L. Sclater & Salvin, 1870 – Pinta (Abington) and Marchena (Bindloe), in N Galapagos Is.
C. f. mentalis Ridgway, 1894 – Genovesa (Tower), in N Galapagos Is.
C. f. bifasciata Ridgway, 1894 – Santa Fe (Barrington), in C Galapagos Is.
C. f. ridgwayi Rothschild & E. J. O. Hartert, 1899 – Floreana (Charles), in S Galapagos Is.
C. f. luteola Ridgway, 1894 – San Cristóbal (Chatham), in SE Galapagos Is.
C. f. cinerascens Ridgway, 1890 – Española (Hood), in SE Galapagos Is.



Descriptive notes. 10 cm; 8 g. A small Darwin's finch with characteristically long and pointed, parulid-like bill, short and weak tail. Has pale sandy-grey head and upperparts, slightly paler supercilium; upperwing sandy brown with narrow pale wingbars, lower one often more evident than upper one; off-white below, pale dusky wash on breast and flanks, buff tone on lower flanks; iris dark; bill blackish when breeding, otherwise dull orange-yellow with dark culmen; legs blackish. Sexes alike. Juvenile is similar to adult. Races differ mainly in plumage coloration: *becki* is larger and darker than nominate, with throat ranging from pale buff to rufescent, flanks olive-grey; *mentalis* is smaller and darker below than nominate; *bifasciata* is palest race, very pale above and below, whitish on underparts; *ridgwayi* male has some cinnamon on throat (less extensive than on *C. olivacea*), female paler than nominate; *cinerascens* is slightly larger and paler than nominate; *luteola* is warmer-toned, yellowish below. VOICE. Often song a repeated series of notes, "chip-pi'pi'pi'pi'pi", sounding like slow trill; song parameters appear constrained by bill size, this small-billed species having relatively high trill rate, and relatively high frequency bandwidth. Similar to song of *C. olivacea* (the two will respond to playback of each other's songs), but present species has longer song with more repetitive notes. Songs on Genovesa (race *mentalis*) frequently have more buzzy notes, while those on Pinta (nominate) lack buzzy notes and are least varied.
Habitat. Arid lowlands of small and low islands. May forage on dry sand beaches at very edge of vegetation.
Food and Feeding. Eats small insects and spiders (Araneae). Adults feed nestlings solely with arthropods. Usually forages in middle storey, but will use all levels including, rarely, ground. Singly or in pairs; sometimes in mixed flocks with other finches.
Breeding. Season Jan–May, on Genovesa beginning soon after first rains; up to three clutches laid within one season. Nest built by male alone, a sphere with entrance towards top and on side, made from dry grasses and vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots; incubation 12 days (10–14); nestling period 13–15 days (11–17).
Movements. Resident.
Status and Conservation. Not globally threatened. Common and widespread.
Bibliography. Armani (1985), Grant, B.R. & Grant (2002a), Grant, P.R. (1982), Grant, P.R. & Grant (1980, 1987, 2003), Grant, P.R. *et al.* (2005), Lack (1947), Petren, Grant, B.R. & Grant (1999a), Petren, Grant, P.R. *et al.* (2005), Podos (2001), Swash & Still (2000), Tonnis *et al.* (2005).

Genus *PLATYSPIZA* Ridgway, 1897

313. Vegetarian Finch
Platyspiza crassirostris

French: Géospize crassirostre **Spanish**: Pinzón de Darwin Vegetariano
German: Dickschnabel-Darwinfink
Other common names: Vegetarian Tree-finch

Taxonomy. *Camarhynchus crassirostris* Gould, 1837, Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Camarhynchus* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Genus sometimes subsumed in *Camarhynchus*, but represents a relatively old lineage within Darwin's finches, having separated out before emergence of *Geospiza* ground-finches, *Camarhynchus* tree-finches and perhaps *Pinaroloxias inornata*. Monotypic.

Distribution. Galapagos Is: on Pinta (formerly Abington I), Marchena (Bindloe), Fernandina (Narborough), Isabela (Albemarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable), Floreana (Charles) and satellites, and San Cristóbal (Chatham).
Descriptive notes. 16 cm; 29–40 g. The largest Darwin's finch, with longer and fuller tail than others, and more vertical stance; broad, stout bill strongly curved on culmen, giving appearance like that of a parrot (Psittacidae). Male has black hood, black continuing down to throat, breast and upper flanks; upperparts olive with blackish feather centres, particularly on mantle close to hood; upperwing and tail dark

brown with paler edging; underparts whitish, obscurely streaked on lower breast and flanks, buffy on lower flanks and undertail-coverts; some birds much more rufous overall, especially on underparts; iris dark; bill black, lower mandible becomes horn-coloured during non-breeding season; legs blackish. Female is brown, streaked on crown, face and upperparts, buffy rump; upperwing and tail brown, indistinct buffy wingbars; off-white below, streaked on throat, breast and flanks, lower flanks washed buff; upper mandible mostly dusky brown to blackish, lower mandible usually dull orange or dull pinkish. Immature male is intermediate between female and male adults, blackish restricted to face and throat, more streaked below than adult male. VOICE. Song a long, nasal drawn-out note, "ph'wheeeuuuuu-iiiúúú", accented towards end, each note nearly 2 seconds in length. Call a high-pitched squealing "tzeeeeiiiiiiiiippppppp", like electronic sound made when tuning in a radio, the most extreme vocalization of all Darwin's finches; also a whining "pheep".
Habitat. Variety of habitats, primarily montane evergreen forest; most common in transition zone, but will venture into arid zone lower down, as well as humid zone higher up.
Food and Feeding. Feeds largely on leaves, flowers, buds and fruits; a true vegetarian, often when sighted has a leaf or bud in bill. Forages mostly at middle levels.
Breeding. Breeds primarily in wet season. Nest domed, with side entrance, made from grass. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon; widespread. No evidence of any population declines.
Bibliography. Armani (1985), Burns *et al.* (2002), Harris (1973), Lack (1947), Swash & Still (2000).

Genus *PINAROLOXIAS* Sharpe, 1885

314. Cocos Finch

Pinaroloxias inornata

French: Spizin de Cocos **German**: Kokosinselammer **Spanish**: Pinzón de Darwin de la Cocos
Other common names: Cocos Island Finch

Taxonomy. *Cactornis inornatus* Gould, 1843, Cocos Island, Costa Rica.
Molecular data support original assertion that this species is part of the group known as "Darwin's finches" (incorporating also *Certhidea*, *Platyspiza*, *Camarhynchus* and *Geospiza*), the only one not found in Galapagos Archipelago; as such, it is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Monotypic.
Distribution. Cocos I, S of Costa Rica.

Descriptive notes. 12 cm; 13·1–16 g. A small finch with long and narrow, finely pointed bill with curved culmen, giving slightly down-curved look, and relatively long tail. Male is almost entirely black, including blackish wings and tail; crissum white with large black feather centres on undertail-coverts; iris dark; bill black throughout year; legs blackish. Female is brownish and streaked throughout, including head; face streaked, often a paler buffy supercilium; mantle and back brown with blackish feather centres, lower back and rump unstreaked and brighter cinnamon-brown; tail brown with variable cinnamon tips and sometimes feather centres; upperwing dark brown, two well-formed paler buff-brown to cinnamon wingbars, tertial edges similar in colour; underparts buff, blackish streaking on breast and flanks, unstreaked belly and vent, rear flanks darker buff; bill orange-yellow with darker culmen. Immature male is similar to female, but more densely and darkly streaked below, and crown and upperparts blackish-brown and less obviously streaked. VOICE. Song a buzzy double note, "chz-zhweeeuu" or "phfft-zheeuu", not unlike those of other Darwin's finches. Calls include high "phzzzzz" and a nasal "phheww".
Habitat. Found in practically every habitat on Cocos I: *Hibiscus* thickets along coasts, woodland, open country and closed-canopy forest, as well as in disturbed vegetation.
Food and Feeding. Feeds on soft fruit, nectar, arthropods and grass seeds. Four main types of foraging activity noted: eating *Cecropia pittieri* fruit, visiting leaf nectaries of *Hibiscus tiliaceus*, gleaning in vine tangles, and gleaning in tree foliage. Individual birds appear to favour particular techniques, resulting in individual specialization in manner in which they forage.
Breeding. Breeds throughout year, mostly Jan–May. Nest built by male, a sphere with entrance towards top and on side, made from dry grasses and vegetation (often moss and lichen used as construction material). Clutch usually 4 eggs, whitish with pinkish or brown spots. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Common to abundant; the most common landbird on Cocos. Appears to have high tolerance of disturbed habitats, such that habitat degradation may not have major adverse effects on it. Nevertheless, this species has a very restricted global range of no more than c. 25 km², and is therefore susceptible to chance catastrophic events; in addition, introduced rats (*Rattus*) and cats are potential predators, grazing by feral deer, pigs and goats degrades natural habitats on the island, and increasing tourism is a further disturbance factor. Although the species is numerous, with an apparently stable population, and is a generalist in habitat preferences, its tiny global range is considered sufficient for it to be considered threatened. The entire island of Cocos is protected as a national park.

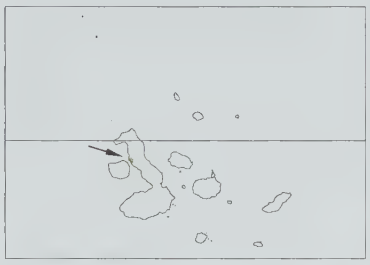
Genus *CAMARHYNCHUS* Gould, 1837

315. **Woodpecker Finch**

Camarhynchus pallidus

French: Géospize pique-bois **Spanish**: Pinzón de Darwin Carpintero
German: Spechtdarwinfink

Taxonomy. *Cactornis pallida* P. L. Sclater and Salvin, 1870, Santa Cruz (formerly Indefatigable Island), Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Three subspecies recognized.
Subspecies and Distribution.
C. p. productus Ridgway, 1894 – Fernandina (formerly Narborough I) and Isabela (Albemarle), in W Galapagos Is.
C. p. pallidus (P. L. Sclater & Salvin, 1870) – Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigabale) and Floreana (Charles), in C & S Galapagos Is.
C. p. striatipecta (Swarth, 1931) – San Cristóbal (Chatham), in SE Galapagos Is.



Descriptive notes. 15 cm; 20–31 g. A medium-sized to larger Darwin's finch with long bill, approximately twice as long as base depth, with arched culmen and nearly straight gonys, strong legs and large feet; short and weak tail. Male is somewhat nondescript sandy brown, unstreaked, and rather pale; face sandy brown, pale area above and below eye, upperparts also sandy brown and unstreaked; upperwing and tail sandy brown, two indistinct pale cinnamon wingbars; buffish below, nearing white on throat and belly to undertail-coverts, some individuals unstreaked, others with indistinct streaking on breast (strongest on side of breast); iris dark; bill black during breeding, paler lower mandible at other times; legs dusky. Female is like male in plumage, but often washed buff, bill dull orange, sometimes with darker culmen and tip, not becoming black during breeding. Juvenile resembles female. Races differ in size and plumage: *productus* is smaller and shorter-billed than nominate, also darker, and with more tendency to be streaked below; *striatipecta* also is smaller and shorter-billed, but much more strongly streaked on breast and flanks, also modestly streaked on upperparts. VOICE. Song loud and carries well, e.g. "chup-tupupupu chup-tupupupu" or "cht-trrr cht-trrr" or "chik-tip-tip-tip-tip chik-tip-tip-tip-tip", sounds more warbled and rollicking than that of congeners; song parameters appear to be constrained by bill size, this larger-billed species having relatively high trill rate and broad frequency bandwidth. Calls include nasal "pheew".
Habitat. Found in variety of habitats and elevations, especially montane evergreen forest; typically most common in transition zone and farther up in humid forest zone.
Food and Feeding. Main foods various types of arthropod, including wood-boring beetle (Coleoptera) larvae. Highly distinctive foraging behaviour, including crawling along branches and trunk-clinging; pecks in manner of a small woodpecker (Picidae) in order to gain access to larvae inside the timber. Makes ingenious use of a tool, usually a short pointed stick, to pry out these larvae; observations have revealed that it will search for a short hard twig, break this to the required length, and use it as a spear with which to impale and extract concealed insect prey. Ecologically, fills the role of a woodpecker or nuthatch (Sittidae), creeping along branches, probing in bark and even in clumps of dry leaves. Singly and in pairs.
Breeding. Nest built by male, a sphere with entrance towards top and on side, made from dry grasses and other vegetation (often moss and lichen used as construction material). Clutch mostly 4 eggs, whitish with pinkish or brown spots. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common, and widespread. Despite its modest appearance, this is one of the most renowned of all bird species, famed primarily for its well-publicized habit of pecking like a small woodpecker and, in particular, of making use of tools.
Bibliography. 316. **Mangrove Finch**

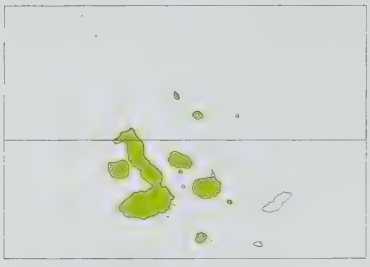
Camarhynchus heliobates

French: Géospize des mangroves **Spanish**: Pinzón de Darwin Manglero
German: Mangrovedarwinfink

Taxonomy. *Geospiza heliobates* Snodgrass and Heller, 1901, Tagus Cove, Isabela (formerly Albemarle Island), Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Monotypic.
Distribution. W Isabela I, in W Galapagos Is.
Descriptive notes. 14 cm; 18 g. A medium-sized Darwin's finch with typically short and weak tail, relatively long bill with arched culmen, nearly straight gonys. Male is nondescript greyish-brown and streaked, face grey-brown, pale area above and below eye, crown darker (older individuals sometimes acquire black hood); upperparts grey-brown and unstreaked to indistinctly streaked; upperwing and tail brown, two indistinct paler wingbars; off-white below, grey-streaked on throat, breast and flanks; iris dark; bill black during breeding, paler lower mandible at other times; legs dusky. Distinguished from similar *C. pallidus* by smaller size, smaller bill, and darker plumage with distinct streaking on breast. Female is like male in plumage, but bill dull orange with darker culmen and tip, not becoming black during breeding. Juvenile resembles female. VOICE. Song a rollicking "chi'priip chi'prriip chi'prrip" or "ch-wee? ch-wee? ch-wee?". Calls include buzzy "zzzzzz-tuu" and high-pitched "zeeeee".

Habitat. Dense and tall stands of mangrove.
Food and Feeding. Feeds largely on arthropods, mainly insects and their larvae, especially beetles (Coleoptera), and spiders (Araneae); also some vegetable matter. Forages principally in dead wood and leaf litter, and in apical buds of red mangrove (*Rhizophora mangle*).
Breeding. Breeds during start of rainy season, from Dec/Jan, into May. Pair-bond may be kept from previous nesting seasons. Nest built by male, a sphere with entrance towards top and on side, made from dry grasses and vegetation (often moss and lichen used in construction), placed in outermost branches in lower canopy of black mangrove (*Avicennia germinans*) or white mangrove (*Laguncularia racemosa*), with pronounced preference for former tree where available; in recent study, all nests located were in tall trees within patches of high mangroves that were often flooded at high tide (such mangroves rare in Galapagos). Clutch usually 4 eggs, whitish with pinkish or brown spots; incubation by female alone, 12 days; nestling period at least 10 days. Nest predation high, 54%, with only 18% ultimately producing young, most predation by rats (*Rattus*); after rat control, predation rate fell to c. 30%; additional mortality of nestlings due to the botfly *Philornis downsi*.
Movements. Resident.
Status and Conservation. CRITICALLY ENDANGERED. Rare, and extremely local. Total population estimated at 80–120 mature individuals, all within a tiny global range of just 1 km² on NW coast of Isabela I. Historically, this species was present in at least six mangrove patches on E Fernandina I and E, S & W Isabela. Recent surveys failed to locate the species on Fernandina, and likely now extinct as a breeding bird on that island (last reported sighting possibly in 1971). On Isabela, breeding populations found in 1997 and 1998 in only two areas, Playa Tortuga Negra (37 pairs) and Caleta Black (21 pairs), both on NW coast of the island; in subsequent surveys of these sites, estimated populations of, respectively, 36 and 16 pairs in 1999, 24 and 14 pairs in 2007, and a combined total of c. 40 pairs in 2009 (this last possibly the most thorough survey); elsewhere on Isabela, 3–5 territories probably with breeding birds identified in fairly extensive mangroves on SE coast, and in 2008 several other historical sites were searched, including Bahia Urbina, Bahia Elizabeth and Punta Moreno (also Punta Espinoza, on Fernandina), but species was found at only one site, Bahia Cártago (on E coast of Isabela), where possibly 4–5 pairs present. Has probably never been common, and in recent decades its range and population have constricted greatly. Declines due mainly to introduced black rat (*Rattus rattus*), which is a major cause of nesting failure, e.g. 70% of nests preyed on in 2007; other potential threats include feral cats and the Smooth-billed Ani (*Crotophaga ani*), both predators; a significant threat is the accidentally introduced botfly *Philornis downsi*, a nest parasite present in all nests and at high rate of infestation (average of 42 parasites per nest). Habitat degradation probably a contributory factor. Mangroves utilized by this species appear structurally different from those where it is absent, suggesting subtle habitat preferences; appears to favour mangrove with tall trees, relatively low canopy cover, and plenty of leaf litter and dead wood; moreover, separation of the mangrove trees from the sea is evidently essential in avoiding washing-away of the leaf litter, a preferred foraging substrate. Whole habitat is protected within Galápagos National Park, and islands are a World Heritage Site (although classified as threatened in 2007). Control of invasive predators is continuing, and study of methods to control *Philornis downsi* is underway. Studies of breeding biology have been undertaken and blood samples analysed; preliminary results appear to indicate serious inbreeding. Feasibility of translocating individuals being assessed, and possible sites for reintroduction on Isabela investigated. Three-year programme involves the taking of ten young annually from Tortuga Negra colony and releasing them into mangroves on E coast (Bahia Cártago). Yearly monitoring continues.
Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Curio & Kramer (1964), Dvorak *et al.* (2004), Fessl, Dvorak *et al.* (2011), Fessl, Loaiza *et al.* (2011), Harris (1973), Hirschfeld (2007), Lack (1947), Stattersfield & Capper (2000), Swash & Still (2000).



317. **Large Tree-finch**

Camarhynchus psittacula

French: Géospize psittacin **Spanish**: Pinzón de Darwin Lorito
German: Papageischnabel-Darwinfink
Other common names: Large Insectivorous Tree-finch

Taxonomy. *Camarhynchus psittacula* Gould, 1837, Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Three subspecies recognized.
Subspecies and Distribution.
C. p. habeli P. L. Sclater & Salvin, 1870 – Pinta (formerly Abington I) and Marchena (Bindloe), in N Galapagos Is.
C. p. affinis Ridgway, 1894 – Fernandina (Narborough) and Isabela (Albemarle), in W Galapagos Is.
C. p. psittacula Gould, 1837 – Santiago (James), Rábida (Jervis), Santa Cruz (Indefatigable), Santa Fe (Barrington) and Floreana (Charles), in C & S Galapagos Is.
Descriptive notes. 13 cm; 15–21 g. The largest tree-finch, tail proportionately short and weak, deep bill approximately as long as it is deep, strongly arched culmen, mandible tips cross slightly when bill closed. Male nominate race has blackish hood extending to throat and breast; upperparts greyish-olive with darker feather centres; whitish below tinged yellowish-buff, dark streaks on lower breast and flanks, undertail-coverts unstreaked buffy white; iris dark; bill black when breeding, otherwise

On following pages: 318. Medium Tree-finch (*Camarhynchus pauper*); 319. Small Tree-finch (*Camarhynchus parvulus*); 320. Sharp-beaked Ground-finch (*Geospiza difficilis*); 321. Common Cactus-finch (*Geospiza scandens*); 322. Large Cactus-finch (*Geospiza conirostris*); 323. Large Ground-finch (*Geospiza magnirostris*); 324. Medium Ground-finch (*Geospiza fortis*); 325. Small Ground-finch (*Geospiza fuliginosa*); 326. Many-colored Chaco Finch (*Saltatricula multicolor*).

dull orange with dark culmen; legs black. Female is dull greyish-brown, streaking of underparts less bold than in male, often indistinct; head greyish-brown, slightly paler supercilium, upperparts greyish-brown with indistinct darker feather centres (sometimes absent), tail brown; upperwing brownish, two narrow grey-buff wingbars; off-white below, indistinct grey streaking on breast on some individuals, belly to undertail-coverts plain pale buff; bill dull orange with darker culmen; legs blackish. Immature male is like female, but with blackish forehead, face and lower throat. Races differ mainly in size and bill structure: *habeli* is smaller than nominate, has longer bill with less curved culmen, male tends to be darker than nominate; *affinis* is like nominate, but smaller in both body size and bill size. VOICE. Song a repeated series of 4–6 notes given in pairs, "chu-tzee chu-tzee chut-zee". Calls include nasal "tzeeuu".

Habitat. Highland forests; may move to lower elevations during dry season.

Food and Feeding. Food mainly arthropods, also native fruits. Forages under leaves and excavates dead branches in search of insects.

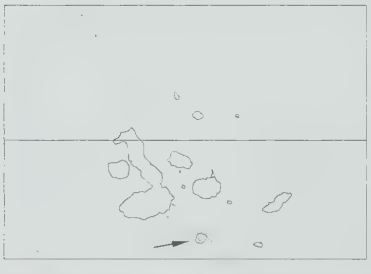
Breeding. Breeds mainly in wet season. Pair-bond may be kept over successive seasons. Nest built by male, a sphere with entrance towards top at side, made from dry grasses and other vegetation (often moss and lichen used in construction). Clutch usually 4 eggs (sometimes 3), whitish with pinkish or brown spots. Incubation by female, c. 12 days; fledging 10–12 days.

Movements. Resident; some downslope movement in dry season suspected.

Status and Conservation. Not globally threatened. Uncommon; widely distributed in the archipelago. Apparently extinct on Pinzón (Duncan) and Baltra (Seymour).

Bibliography. Armani (1985), Curio & Kramer (1965b), Harris (1973), Lack (1947), McCarthy (2006), Swash & Still (2000), Tebbich *et al.* (2004).

318. **Medium Tree-finch**



Camarhynchus pauper

French: Géospize modeste **Spanish**: Pinzón de Darwin Modesto
German: Kleinschnabel-Darwinfink
Other common names: Charles (Insectivorous) Tree-finch, Santa Maria/Floreana Tree-finch

Taxonomy. *Camarhynchus pauper* Ridgway, 1890, Floreana (formerly Charles Island), Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Monotypic.

Distribution. Highlands of Floreana I, in S Galapagos Is.

Descriptive notes. 13 cm; 16 g. Intermediate-sized tree-finch, larger body size than *C. parvulus* and with bill distinctly larger and longer; typically has proportionately short and weak tail. Male has blackish hood extending to throat and breast; upperparts brownish-olive with darker feather centres; underparts pale buffy or whitish, blurry streaks on lower breast and flanks, unstreaked undertail-coverts buffy white; iris dark; bill black when breeding, otherwise dull orange with dark culmen; legs black. Female is dull greyish-brown, essentially unstreaked or only indistinctly streaked: head greyish-brown, slightly paler supercilium, upperparts also greyish-brown with indistinct darker feather centres (sometimes absent); tail brown; upperwing brownish, two narrow grey-buff wingbars; off-white below, indistinct grey streaking on breast on some individuals, belly to undertail-coverts pale buff and unstreaked; bill dull orange with darker culmen; legs blackish. Immature male is like female, but has blackish forehead, face and lower throat. VOICE. Song a repeated series of notes, lasting c. 1·5 seconds, "che-che-che-che-che" or "tew-tew-tew-tew" or "chi'ri'ri chi'ri'ri". Calls include high-pitched "zweee" and nasal "phwee."

Habitat. Forested habitats at middle and higher elevations, 300–400 m. Inhabits montane evergreen and tropical deciduous forests, and humid scrub in *Scalesia* zone. May move downslope to dry areas during non-breeding season.

Food and Feeding. Mainly small arthropods, also young buds and nectar and leaves. Forages by probing in bark crevices and branches; searches under foliage and twigs. Gleaning items from leaves and twigs.

Breeding. Nest built by male, a sphere with entrance towards top and at side, made from dry grasses and other vegetation (often moss and lichen used in construction), placed preferentially in native *Scalesia pedunculata* tree. Clutch generally 4 eggs, whitish with pinkish or brown spots; no information on incubation period; nestling period 13–16 days. Of 63 active nests studied, 17 held combined total of 53 chicks, all of which were infested with the parasitic botfly *Philornis downsi*; only 25% of nestlings fledged, 28% were lost to predation, 41% died through *P. downsi* parasitism, and 6% died for other reasons.

Movements. Resident but some down slope movement after the breeding season.

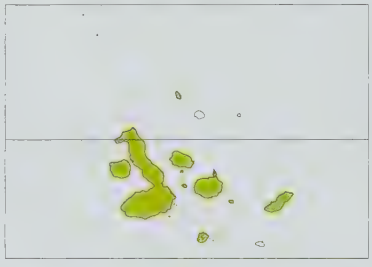
Status and Conservation. CRITICALLY ENDANGERED. Local and uncommon. Appears to be in rapid decline. Has tiny global range of c. 23 km², within which estimated population in 2008 at most 1660 individuals, a reduction of more than 60% since 2004. Small to moderate-sized population in highlands, with largest numbers around base of volcano Cerro Pajas, where preferred nesting tree, *Scalesia pedunculata*, dominant; uncommon to rare on coast. At Cerro Pajas, density dropped from 154 birds/km² in 2004 to 60 birds/km² in 2008, and this species is now significantly less common than it was 50–100 years ago. Main causes of the rapid decrease in this species' numbers are habitat degradation, introduced predators and, especially, effects of the accidentally introduced nest-parasitic botfly *Philornis downsi*. The fly appears to be causing large-scale decreases in nesting productivity; the risk of fly parasitism thought to be increased because this tree-finch's only habitat is adjacent to cleared agricultural land with fruiting trees favoured by the adult fly. In addition, avian pox infects a significant proportion of individuals. Floreana I has several introduced predators and herbivores, including, among others, pigs, cats, dogs and rats (*Rattus*), and suffers extensive habitat destruction and degradation from agriculture and free-ranging domestic stock, as well as habitat alteration caused by invasive plant species. The tree-finch's preferred nesting tree, *Scalesia pedunculata*, is now endangered on Floreana, surviving only in fragmented patches totalling less than 4 km² in extent; visits by tourists to *Scalesia* habitat have increased more than ten-fold since 2004. Galápagos National Park includes almost all land area of islands, but does not incorporate the agricultural zone of Floreana, an area which was this tree-finch's prime habitat; the islands are a World Heritage Site (although classified as threatened in 2007). In 2006, eradication of goats and donkeys on Floreana commenced, and this significantly reduced populations of these grazing mammals. Methods to control or eradicate *Philornis downsi* are currently being tested.

Bibliography. Anon. (2010c), Armani (1985), Butchart & Stattersfield (2004), Curio & Kramer (1965b), Harris (1973), Lack (1947), McCarthy (2006), O'Connor *et al.* (2010), Stattersfield & Capper (2000), Swash & Still (2000).

319. **Small Tree-finch**

Camarhynchus parvulus

French: Géospize minuscule **German**: Zwergdarwinfink **Spanish**: Pinzón de Darwin Chico
Other common names: Small Insectivorous Tree-finch



Taxonomy. *Geospiza parvula* Gould, 1837, Santiago (formerly James Island), Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Geospiza*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Two subspecies recognized.

Subspecies and Distribution.

C. p. parvulus (Gould, 1837) – Pinta (Abington), Fernandina (Narborough), Isabela (Albemarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable), Santa Fe (Barrington) and Floreana (Charles), in Galapagos Is.

C. p. salvini Ridgway, 1894 – San Cristóbal (Chatham), in SE Galapagos Is.

Descriptive notes. 11 cm; 11–16 g. The smallest tree-finch, with tiny rounded bill shape similar to that of some *Sporophila* seedeaters; proportionately short and weak tail. Male nominate race has blackish hood extending to throat and breast; upperparts greyish-olive with darker feather centres; underparts whitish with buffy tinge, blurry streaks on lower breast and flanks, unstreaked undertail-coverts buffy white; iris dark; bill black when breeding, otherwise dull orange with dark culmen; legs black. Female is dull greyish-brown, essentially unstreaked above and at most indistinctly streaked below: head greyish-brown, slightly paler area above and below eye, upperparts similarly greyish-brown; tail brown, upperwing brownish, two narrow grey-buff wingbars; off-white to pale buff below, indistinct grey streaking on breast on some individuals, belly to undertail-coverts pale buff and unstreaked; bill dull orange with darker culmen, legs blackish. Immature male is like female, but with blackish forehead, face and lower throat. Race *salvini* is slightly larger than nominate, with longer bill, lacks dark hood, also more yellowish-buff and more strongly streaked on underparts. VOICE. Song a high-pitched double note, "zee-tzee, zee-tzee"; song parameters appear constrained by bill size, this small-billed species having relatively high trill rate, and relatively low frequency bandwidth.

Habitat. Forest areas, agricultural land with trees, also in parts of drier zone where tall shrubs and other vegetation present. At all elevations, from arid zone to highland humid zone; most common from transition zone and above.

Food and Feeding. Diet mostly insects and other small arthropods; also seeds, fruit, buds, and sometimes flower nectar. Forages mostly above ground in foliage, occasionally on ground. Techniques include gleaning from leaves and twigs, as well as hanging from tips of branches, often upside-down, to glean items from leaves, buds and twig tips.

Breeding. Nest built by male, a sphere with entrance at side towards top, made from dry grasses and other vegetation (often moss and lichen used in construction). Clutch usually 4 eggs, whitish with pinkish or brown spots. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Common and widespread. Appears to be the most common and the most widespread of the Galapagos tree-finches.

Bibliography. Armani (1985), Christensen & Kleindorfer (2007), Christensen, Kleindorfer & Robertson (2006), Christensen, Robertson & Kleindorfer (2010), Curio & Kramer (1965b), Harris (1973), Kleindorfer *et al.* (2009), Lack (1947), McCarthy (2006), Podos (2001), Swash & Still (2000), Tebbich *et al.* (2004), Wiggins (1965).

Genus *GEOSPIZA* Gould, 1837

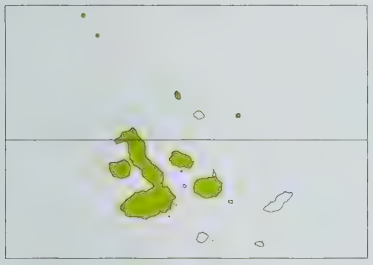
320. **Sharp-beaked Ground-finch**

Geospiza difficilis

French: Géospize à bec pointu **Spanish**: Pinzón de Darwin Picofino
German: Spitzschnabel-Grundfink
Other common names: Vampire Finch (*septentrionalis*)

Taxonomy. *Geospiza difficilis* Sharpe, 1888, Pinta (formerly Abington Island), Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. A form *G. nebulosa* was described in 1837 from two specimens, one from Floreana (Charles); relationships uncertain, but, if this is conspecific with present species, name *nebulosa* would have priority; *nebulosa* has been considered a synonym of *G. fortis*. Relationship of present species to other members of genus has always been troubled (hence the name *difficilis*); hybridizes occasionally with *G. conirostris*. Considerable differences exist in habits, ecology, size, and bill shape among its different populations. Recent genetic work suggests that interior island populations, which are restricted to highlands on Pinta, Fernandina (Narborough) and Santiago (James), form a well-sup-



ported clade which may be only distantly related to others in genus, although, from current data, exact relationship not clear. Present species may warrant division into more than one species, e.g. has been suggested that race *septentrionalis* merits elevation to species rank. Also, Genovesa population, currently included in nominate, appears genetically distantly related to Pinta population, and it may be better to resurrect name *acutirostris* for it; indeed, Genovesa population seems genetically closer to other members of genus, suggesting that it should be removed altogether from present species. Full review required. Three subspecies currently recognized.

Subspecies and Distribution.

G. d. septentrionalis Rothschild & E. J. O. Hartert, 1899 – Darwin (Culpepper) and Wolf (Wenman), in extreme NW Galapagos Is.

G. d. difficilis Sharpe, 1888 – Pinta and Genovesa (Tower), in N Galapagos Is.

G. d. debilirostris Ridgway, 1894 – Fernandina (Narborough), Isabela (Albemarle), Santiago (James) and Santa Cruz (Indefatigable), in W & C Galapagos Is.

Descriptive notes. 11–12 cm; 12·3–20 g. A small ground-finch with small, sharply pointed bill distinctly longer than it is deep and with culmen straight, giving more pointed and longer look than bill of *G. fuliginosa*; relatively short and weak-looking tail. Male nominate race is almost entirely black, with slightly browner wings and tail, undertail-coverts with white fringes; iris dark; bill black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding; legs blackish. Female has head down to throat and upperparts dark olivaceous-brown with brownish or olive-grey fringing (head looks weakly streaked and upperparts rather scaly); wing dark brown with buff fringing, tail feathers dark with greyish edging; buff upper half of eyering; underparts boldly streaked dark brown and buff, the streaks becoming obscure on rear underparts, undertail-coverts rather plain whitish-buff; bill dark with orange tint at base and yellow tip, ranging to entirely orange-yellow (depending on breeding state), legs blackish. Immature male is intermediate between streaked female and solidly black adult male, has head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Race *septentrionalis* is larger than nominate, has longer and more sharply pointed bill with more curved culmen, female and immature on average darker in coloration and with cinnamon wingbars; *debilirostris* is large, with proportionately large feet, and proportionately thick-based, sharply pointed bill. Voice. Song on Wolf I often a long (just over 1 second) single rasping note, reminiscent of song of an *Agelaius* blackbird, "chrrheeeewwww"; also on Wolf, a doubled or tripled note, "zheww-zheew, zheww-zheew". On Genovesa song a nasal "tzh-waa tzh-waa". Calls include very high "tzeeeewwww". Males of genus, with rare exceptions, sing only one song type. Song of present species exhibits much geographical variation: in forest-based populations of Fernandina, Santiago and Pinta songs complex both in tempo and in note structure, and have much frequency modulation and use of high-pitched notes; on low scrubby islands of Genovesa, Wolf and Darwin songs short and structurally simple, usually a repeated simple note or a narrow frequency-band buzz, lacking strong frequency modulation. More complexities exist, but next to each other populations from Wolf and Darwin differ radically, those from Darwin giving simple buzzy trill, those from Wolf having short multi-note songs.

Habitat. In highlands of Fernandina, Santiago and Pinta occupies structurally complex and dense *Zanthoxylum* forest. On N low islands of Darwin, Wolf and Genovesa found in arid scrub habitats, as well as within seabird colonies (particularly race *septentrionalis* of Darwin and Wolf).

Food and Feeding. Variety of foods, including leaves, flowers, cactus pulp and insects. In one study on Genovesa I, adults of this species, *G. magnirostris* and *G. conirostris* showed much overlap in food choice during nesting period. All feed nestlings on mixed diet of arthropods, fruits and seeds. Seeds of *Bursera graveolens* absent from diet of small-billed present species, but common in that of large-billed *G. magnirostris*. During non-breeding season diets diverge, and seed size eaten then correlates to bill size. On Darwin I and Wolf I race *septentrionalis* has extraordinary habit of drinking blood from seabirds; it pecks at feather bases on large seabirds, often where a feather is growing, and then "licks up" the blood as it begins to flow.

Breeding. Highland populations breed largely during wet season; on Genovesa season spans Jan–May, beginning soon after first rains; up to five clutches laid within one season. Nest built by male, a sphere with entrance towards top and on side, made from dry grasses and vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots; incubation period 12 days (10–14); nestling period 13–15 days (11–17).

Movements. Resident; highland populations appear to drift lower into drier habitats during non-breeding season.

Status and Conservation. Not globally threatened. Common on N arid low islands, uncommon in highlands. Widespread, and generally showing no signs of any decrease in numbers, although possibly extirpated on Santa Cruz.

Bibliography. Abbott *et al.* (1977), Armani (1985), Bowman & Billeb (1965), Curio (1969), Curio & Kramer (1965b), Grant, B.R. & Grant (2002b), Grant, P.R. (1982), Grant, P.R. & Grant (1980, 1987), Grant, P.R., Grant & Petren (2000a), Harris (1973), Lack (1947), Lewin (1983), McCarthy (2006), Petren *et al.* (2005), Ratcliffe & Grant (1983), Schluter (1982b, 1984, 1986), Schluter & Grant (1982, 1984), Swash & Still (2000), Vagvolgyi & Vagvolgyi (1989).

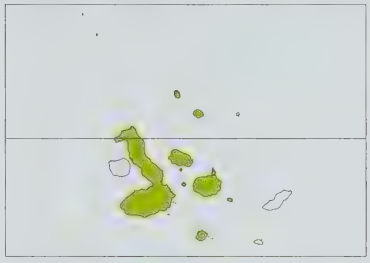
321. Common Cactus-finch

Geospiza scandens

French: Géospize des cactus **Spanish**: Pinzón de Darwin de los Cactos
German: Kaktusgrundfink
Other common names: (Small) Cactus-finch, Cactus Ground-finch

Taxonomy. *Cactornis scandens* Gould, 1837, Santiago (formerly James Island), Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Present species hybridizes rarely with *G. fortis*. Birds on Rábida I (Jervis), currently included in nominate race, are larger-billed than those on Santiago and perhaps better placed in *intermedia*. Four subspecies recognized.



Subspecies and Distribution.

G. s. abingdoni (P. L. Sclater & Salvin, 1870) – Pinta (Abington), in N Galapagos Is.

G. s. rothschildi Heller & Snodgrass, 1901 – Marchena (Bindloe), in N Galapagos Is.

G. s. intermedia Ridgway, 1894 – Isabela I (Albemarle), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable), Santa Fe (Barrington) and Floreana (Charles), in W, C & S Galapagos Is.

G. s. scandens (Gould, 1837) – Santiago and Rábida (Jervis), in C Galapagos Is.

Descriptive notes. 12–14 cm; 20–24 g. A medium-sized ground-finch with long, robust spike-like bill nearly twice as long as it is deep, relatively thick at base, and with distinct droop (downcurved culmen); relatively short and weak-looking tail. Male nominate race is almost entirely black, with slightly browner wings and tail, white crissum with black centres on undertail-coverts; iris dark; bill black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding; legs blackish. Distinguished from extremely similar *G. fortis* only by bill morphology and size, with clearly long and droopy bill. Female has head to throat and upperparts dark grey, with olivaceous-brown to greyish scaling, side of head similar but for buffy eyering and faint buffy bands on supraloral and cheek; wing and tail feathers dark olive-brown to blackish, with buffy-brown fringing, duller on primaries and rectrices; underparts whitish with dark brown streaks all over, the streaks more blurry on rear flanks, and smallest on central belly and vent; bill dark with orange tint at base and yellow tip, varying to entirely orange-yellow (depending on breeding state). Immature male is intermediate between streaked female and solidly black adult male, head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Races differ mainly in size and in bill proportions: *intermedia* is larger than nominate, with proportionately thicker and longer bill; *abingdoni* is larger still, with bill deeper, with strongly arched culmen (specimens of both sexes, are streaked below, suggesting constant plumage difference, although this perhaps an effect of small sample sizes in collections); *rothschildi* is thickest-billed and largest-bodied race. Voice. Song a doubled note, "zhhwe zhhwe", or more complex version, "zhh-wah-wah, zhh-wah-wah". Call a high "tiip". Male ground-finches, with rare exception, sing only one song type; song parameters appear constrained by bill size, this relatively large-billed species having relatively low trill rate, and broad frequency bandwidth. In studies of songs of father and sons on Daphne Mayor I (islet W of Baltra), sons found to learn songs from fathers; songs therefore culturally passed on.

Habitat. Found in arid zone, where prickly-pear cactus (*Opuntia*) present; rarely ventures higher, into more humid zones.

Food and Feeding. Feeds on prickly-pear cactus pulp, flowers, fruits and insects. Primarily a specialist on *Opuntia* seeds, which make up more than a third of diet; another third comprises *Opuntia* flowers, approximately a quarter of diet consists of small seeds, and the rest includes tiny proportion of arthropods and *Tribulus* seeds.

Breeding. May breed at any time of year, but most breeding occurs during wet season; in wet years more than one brood may be raised. Nest normally no higher above ground than 3 m, usually placed in a thick stand of *Opuntia* cactus, but a few are situated in dense shrubs; nest, built by male, a sphere with entrance at side towards top, made from dry grasses and other vegetation. Clutch usually 3–4 eggs, whitish with pinkish or brown spots. Incubation by female, 12 days; young remain in nest c. 11–14 days.

Movements. Resident.

Status and Conservation. Not globally threatened. Common and widespread.

322. Large Cactus-finch

Geospiza conirostris

French: Géospize à bec conique **Spanish**: Pinzón de Darwin Conirrostro
German: Opuntiengrundfink
Other common names: (Large) Cactus Ground-finch

Taxonomy. *Geospiza conirostris* Ridgway, 1890, Española I (formerly Hood Island), Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. On Genovesa (Tower), this species hybridizes rarely with *G. magnirostris* and sometimes with smaller *G. difficilis*. Genetic studies suggest that Española and Genovesa populations are rather distantly related, which would make present taxonomic arrangement paraphyletic; NW populations (*darwini*), however, not sampled, although those on Darwin (Culpepper) and Wolf (Wenman) similar in bill size to those on Genovesa. Three subspecies recognized.

Subspecies and Distribution.

G. c. darwini Rothschild & E. J. O. Hartert, 1899 – Darwin I and Wolf I, in extreme NW Galapagos Is.

G. c. propinqua Ridgway, 1894 – Genovesa, in N Galapagos Is.

G. c. conirostris Ridgway, 1890 – Española, in SE Galapagos Is.

Descriptive notes. 13–15 cm; 28 g. A large ground-finch with thick, yet long and robust bill; relatively short and weak-looking tail. Male nominate race is entirely black with slightly browner wings and tail, except for white crissum with black feather centres on undertail-coverts; iris dark; bill black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding; legs blackish. Distinguished from very similar *G. magnirostris* by longer and thinner bill. Female is dark brownish-grey and streaked throughout, with the paler feather fringes of head, back and most of breast often narrow and indistinct so that these areas appear rather more solid dark than in females of congeners; often with paler buffy-grey supercilium and paler lower eye-crescent (on darker birds, supercilium restricted to a pale spot above and behind eye); upperwing brown with paler, buffy-brown wingbars and tertial edges; below, off-white with darker brown streaking, streaks most dense on throat and breast (breast and throat on some solidly brownish), least dense on belly and vent, undertail-coverts with broad whitish fringes; bill

dusky with variable amounts of dull orange, especially on lower mandible, varying to entirely orange-yellow (depending on breeding state). Immature male is intermediate between streaked female and solidly black adult male, head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Races differ in size and bill proportions: *propinqua* is smaller and has thinner (more laterally compressed) bill than nominate, female paler and more clearly streaked throughout; *darwini* has slightly deeper, heavier bill than nominate, and often an olive wash on rump of male. Voice. Song a doubled nasal note, "ch'whuuu ch'whuuu" or "tcheuu tcheeuu". Male ground-finches, with rare exceptions, sing only one song type. Among Darwin's finches large-billed species are less varied in vocal quality than are small-billed ones, but present species has relatively high trill rate for a large-billed species (although frequency range similar to that of *G. magnirostris*). Calls include high-pitched "tzeeeeee".

Habitat. Arid lowland areas of dry scrub, as well as areas with prickly pear cactus (*Opuntia*).

Food and Feeding. Feeds on prickly-pear cactus pulp, flowers, fruits and insects. In one study on Genovesa I, adults of present species, *G. difficilis* and *G. magnirostris* showed much overlap in food during nesting period, all feeding nestlings with mixed diet of arthropods, fruits and seeds. Seeds of *Bursera graveolens* absent from diet of small-billed *G. difficilis*, but common in that of large-billed *G. magnirostris*, while parts of *Opuntia helleri* were fed to young of present species. During non-breeding season diets diverge, seed size eaten then correlating with bill size.

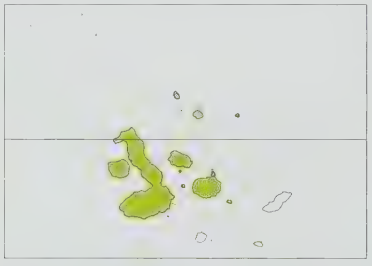
Breeding. Season on Genovesa Jan–May, beginning within a week of first rains; up to four clutches within one season. Nest built by male, a sphere with entrance towards top and at side, made from dry grasses and other vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots; incubation period 12 days (10–14); nestling period 13–15 days (11–17).

Movements. Resident.

Status and Conservation. Not globally threatened. Common on the few islands on which it is found. Appears not to be undergoing any detectable population decline.

Bibliography. Abbott *et al.* (1977), Armani (1985), Curio & Kramer (1965a, 1965b), DeBenedictis (1966), Downhower (1976, 1978), Drozdov (1972), Grant, B.R. (1984, 1985), Grant, B.R. & Grant (1979, 1981, 1982, 1983, 1984, 1987, 1989a, 1989b), Grant, P.R. (1982, 1983), Grant, P.R. & Grant (1980, 1987), Harris (1973), Koster (1985), Lack (1947), Lewin (1983), McCarthy (2006), Petren *et al.* (2005), Schluter & Smith (1986), Swash & Still (2000).

323. **Large Ground-finch**



Geospiza magnirostris

French: Géospize à gros bec **German**: Großgrundfink **Spanish**: Pinzón de Darwin Picogordo

Taxonomy. *Geospiza magnirostris* Gould, 1837, Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Present species hybridizes rarely with *G. conirostris* on Genovesa; on Santa Cruz, large-scale hybridization with *G. fortis* thought to have occurred. Monotypic.

Distribution. Galapagos Is: islands of Pinta (Abington), Marchena (Bindloe), Genovesa (Tower), Fernandina (Narborough), Isabela (Albemarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable) and Santa Fe (Barrington); formerly also Floreana (Charles) and satellites.

Descriptive notes. 15–16 cm; 27–39 g. A large ground-finch with massive bill often as deep as it is long and appearing as deep as entire head, base of lower mandible thick and obvious, as is angle of cutting edge, and bill wide (particularly when viewed from below); considerable variation in bill size; relatively short and weak-looking tail. Male is almost entirely black, with slightly browner wings and tail; crissum white with some blackish streaking; iris dark; bill is black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding period; legs blackish. Female is dark brown with sandy-buff to grey fringing, giving a scaled appearance over all; head and breast instead appear rather streaked, the fringing broadening and becoming paler buffy down breast, with dark centres smallest and rather obscure on central belly to undertail-coverts; darkest birds look rather hooded, with side of head plain but for narrow, short pale line above eye; bill dark with orange tint at base and yellow tip, varying to entirely orange-yellow (depending on breeding state). Immature male is intermediate between streaked female and solidly black adult male, head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Distinguished from very similar *G. fortis* by bill structure, body size, and voice; from very similar *G. conirostris* mainly by structure and shape of bill. Voice. Classic song a nasal repetition of 2 or 3 notes, "chzweee-chzwee", notes lower in pitch than those of *G. fortis* and more slowly delivered. Calls include high-pitched "tzeeeeppp". Male ground-finches, with rare exceptions, sing only one song type. Song parameters appear constrained by bill size, this large-billed species having low trill rate, and very narrow frequency bandwidth; of several Darwin's finches studied, this one, because of its large bill size, has the most constraints in vocal capabilities.

Habitat. Arid scrub in lowland areas.

Food and Feeding. Feeds on large seeds, fruits and caterpillars. In one study on Genovesa I, adults of this species, *G. difficilis* and *G. conirostris* showed much overlap in food selection during nesting period, all feeding nestlings with mixed diet of arthropods, fruits and seeds. Seeds of *Bursera graveolens* common in diet of present species (large-billed), but absent from diet of small-billed *G. difficilis*. Diets of the three species diverge during non-breeding season, at which time size of seeds eaten correlates with bill size.

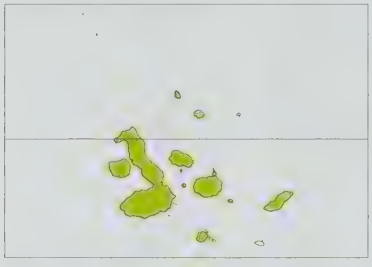
Breeding. Season on Genovesa Jan–May, beginning soon after first rains; up to four clutches laid within one season. Nest built by male, a sphere with entrance towards top at side, made from dry grasses and other vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots; incubation period 12 days (10–14); nestling period 13–15 days (11–17).

Movements. Resident.

Status and Conservation. Not globally threatened. Common and widespread. Present on most islands of Galapagos. Apparently now extinct on Floreana I.

Bibliography. Abbott *et al.* (1977), Armani (1985), Boag & Grant (1984), Curio & Kramer (1965b), Ford *et al.* (1973), Grant, B.R. (2004), Grant, P.R. (1981, 1982), Grant, P.R. & Grant (1980, 1987, 1995a, 2006), Grant, P.R. *et al.* (2001), Harris (1973), Lack (1947), McCarthy (2006), Podos (2001), Schluter (1982a), Steadman (1984), Sulloway (1982a, 1982b), Swash & Still (2000).

324. **Medium Ground-finch**



Geospiza fortis

French: Géospize à bec moyen **Spanish**: Pinzón de Darwin Picomediano
German: Mittelgrundfink

Taxonomy. *Geospiza fortis* Gould, 1837, Galapagos Islands.

Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Present species hybridizes rarely with *G. fuliginosa* and with *G. scandens*; on Santa Cruz, large-scale hybridization with *G. magnirostris* thought to have occurred. Monotypic.

Distribution. Galapagos Is: islands of Pinta (Abington), Marchena (Bindloe), Fernandina (Narborough), Isabela (Albemarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable), Santa Fe (Barrington), Floreana (Charles) and offshore islets, and San Cristóbal (Chatham).

Descriptive notes. 11–12 cm; 18–32 g. A medium-sized ground-finch with relatively thick bill slightly longer than it is deep (bill size variable from island to island, and may change slightly depending on alterations in abundance of small/large seeds caused by El Niño–Southern Oscillation events); relatively short and weak-looking tail. Male is almost entirely black, with slightly browner wings and tail; white crissum with black feather centres on undertail-coverts; iris dark; bill black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding period; legs blackish. Distinguished from very similar *G. fuliginosa* and *G. magnirostris* by bill structure, body size and voice. Female is dark brown with pale buffy fringing all over, looking comparatively paler than congeners, with a more regular pattern, and with less contrast between darker upperparts and paler underparts; pale fringing predominates on head, especially on supraloral area and broken eyering, ear-coverts light buffy with dark streaks, side of neck almost unstreaked pale buffy; mantle, scapulars and upperwing appear more scaly, becoming streaked again on uppertail-coverts; rows of dark streaks on underparts become obscure on rear flanks and especially on central belly and vent; bill dark with orange tint at base and yellow tip, varying to entirely orange-yellow (depending on breeding state). Immature male is intermediate between streaked female and solidly black adult male, head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Voice. Classic song a nasal repetition of 2 or 3 notes, "clzee clzee" or "tzeeuu tzeeuu tzeeuu", on average lower-pitched than that of *G. fuliginosa*. Calls include high-pitched whistle, "zeeeep", and nasal "chhhp". Male ground-finches, with rare exception, sing only one song type. In studies of songs of father and sons on Daphne Mayor I (W of Baltra), sons found to learn songs from fathers. Song parameters appear constrained by bill size, this relatively large-billed species having low trill rate, and relatively wide frequency bandwidth.

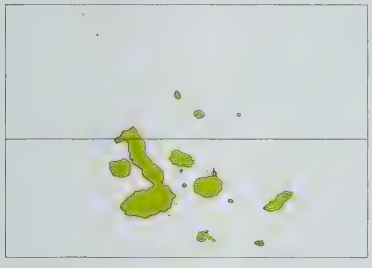
Habitat. Mostly occurs in scrub and at forest edge. Found at all elevations and in all habitats, but most common in arid and transition zones; numbers in highlands greatest during non-breeding season.

Food and Feeding. A generalist in diet, made possible by its intermediate and variable bill size. Variety of seeds, fruits and insects. Generally, more than 50% (but less than 75%) of diet consists of small seeds; next most important *Opuntia* cactus seeds, remainder (in decreasing order of abundance) *Opuntia* cactus flowers, seeds of *Tribulus*, and arthropods. On Daphne Mayor, after large rains of 1982–1983 El Niño event, small seeds (*Cacabus miersii*) became abundant and large seeds (*Tribulus cistoides*) rare, and selection occurred against individuals with larger and wider bill; after El Niño, population of present species on this small island exhibited decrease in mean bill size owing to natural selection for individuals able to forage more efficiently on smaller seeds; in addition, hybrids with *G. fuliginosa*, with their smaller bills, likewise showed improved success.

Breeding. Nest built by male, a sphere with entrance towards top and on side, made from dry grasses and other vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots. Incubation c. 12 days; fledging 10–14 days.

Movements. Resident; some upslope movement during non-breeding season.

Status and Conservation. Not globally threatened. Abundant and widespread. Present on most islands of the Galapagos Archipelago.



Bibliography. Abbott *et al.* (1977), Armani (1985), Boag (1983, 1984), Boag & Grant (1978, 1981, 1984), Curio & Kramer (1965b), Ford *et al.* (1973), Gibbs (1988, 1990), Gibbs & Grant (1987a, 1987b, 1989), Gibbs *et al.* (1984), Grant, B.R. 325. **Small Ground-finch**

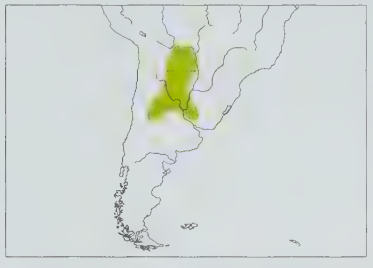
Geospiza fuliginosa

French: Géospize fuligineux **German**: Kleingrundfink **Spanish**: Pinzón de Darwin Fuliginoso

Taxonomy. *Geospiza fuliginosa* Gould, 1837, Galapagos Islands.
Recent molecular-genetic research suggests that the Galapagos group consisting of present genus and *Certhidea*, *Platyspiza* and *Camarhynchus*, known collectively as "Darwin's finches", is allied to the tanagers (Thraupidae), being closest to *Coereba*, *Tiaris* and several Caribbean genera. Present species hybridizes rarely with *G. fortis*. Monotypic.
Distribution. Galapagos Is: islands of Pinta (formerly Abington I), Marchena (Bindloe), Fernandina (Narborough), Isabela (formerly Albemarle), Santiago (James), Rábida (Jervis), Pinzón (Duncan), Baltra (Seymour), Santa Cruz (Indefatigable), Santa Fe (Barrington), Floreana (Charles) and satellites, San Cristóbal I (Chatham) and Española (Hood).

Descriptive notes. 10–10·5 cm; 12–17 g. The smallest member of genus, with small and dainty bill slightly longer than it is deep and with culmen relatively straight, giving more clearly triangular shape than more round-topped bill of *G. fortis*; relatively short and weak-looking tail. Male is almost entirely black, slightly browner on wings and tail; crissum white, with black feather centres on undertail-coverts; iris dark; bill black during breeding period, becoming brown with orange tint at base and yellow at tip during transition, and orange-yellow during non-breeding period; legs blackish. Distinguished from otherwise identical *G. fortis* and *G. magnirostris* by bill structure, body size, and voice. Female is dark grey-brown to dark olive-brown with greyish fringing on head and upperparts, giving scaly appearance, or sometimes rather streaked on head, especially crown, and neck; rump to uppertail-coverts more evenly greyish; wings and tail dark brown with bold pale buff fringes; side of head rather streaked, not contrasting with crown, loral region and eyering buff, sometimes with irregular blackish line across central lores; submoustachial region to throat pale buff and somewhat variable, sometimes with tiny dark spots and separated by a row of dense dark streaks on malar region, but sometimes profusely streaked all over; underparts streaked dark on pale buff to whitish background colour, central belly and vent almost plain whitish; bill dark with orange tint at base and yellow tip, varying to entirely orange-yellow (depending on breeding state). Palest (young) females may look almost unstreaked, and similar to *Camarhynchus parvulus*, but habitually have some diffuse streaking on crown, a more distinct face pattern with pale streak above eye, and straighter culmen and gonys. Immature male is intermediate between streaked female and solidly black adult male, head usually solidly black, as is breast, but diffuse streaking present on belly and back, wings more blackish than on female, and wing-coverts and tertials crisply edged buff. Voice. Classic songs tend to repeat 2 buzzy or nasal notes, "clzeeuu clzeeuu" or "chzzuu chzuuu", with several seconds between repetition of the paired notes; notes sometimes tripled, rather than paired. Male ground-finches, with rare exceptions, sing only one song type. Song parameters appear constrained by bill size, this small-billed species having relatively low trill rate, and broad frequency bandwidth.
Habitat. Found in all habitats at all elevations, and most common in arid and transition zones; numbers in highlands greatest in non-breeding season.
Food and Feeding. Varied diet includes small seeds, buds and insects. Bulk of diet consists of small seeds; much of remainder made up of arthropods, with small amounts of *Opuntia* cactus seeds.
Breeding. Nest built by male, a sphere with entrance towards top at side, made from dry grasses and other vegetation. Clutch usually 4 eggs, whitish with pinkish or brown spots. No other information.
Movements. Largely resident; some upslope movements in non-breeding season. Some dispersal between islands apparent; arrives periodically on Daphne I (W of Baltra), where no stable population of this species.
Status and Conservation. Not globally threatened. Common to abundant; widespread and found in all habitats. Occurs on almost all islands of the Galapagos Archipelago.
Bibliography. Abbott *et al.* (1977), Amadon (1967), Armani (1985), Boag & Grant (1984), Christian (1980), Curio (1969), Curio & Kramer (1965b), Downhower (1976, 1978), Dudaniec *et al.* (2006), Grant, B.R. (2004), Grant, B.R. & Grant (1993, 1996, 2002a), Grant, P.R. & Grant (1994, 1997a, 1997b), Harris (1973), Kleindorfer & Dudaniec (2006), Kleindorfer *et al.* (2006), Kushlan (1983), Lack (1947), Lewin (1983), MacFarland & Reeder (1974), McCarthy (2006), Podos (2001), Ratcliffe & Grant (1983), Schluter (1982a, 1982b, 1984, 1986), Schluter & Grant (1982, 1984), Schluter *et al.* (1985), Swash & Still (2000), Vagvolgyi & Vagvolgyi (1989).



Genus *SALTATRICULA* Burmeister, 1861

326. **Many-colored Chaco Finch**

Saltatricula multicolor

French: Saltatricule du Chaco **German**: Vielfarbenammer **Spanish**: Pepitero-Chico
Other common names: Many-colored Chaco Sparrow

Taxonomy. *Saltator multicolor* Burmeister, 1860, Paraná, Entre Ríos, Argentina.
Molecular data indicate that genus is more closely related to the tanagers (Thraupidae) than to members of present family; furthermore, this species was found to be embedded within genus *Saltator*, as sister-species of Black-throated Saltator (*Saltator atricollis*), with the *Saltator* clade sister to all other Thraupidae. Further research required. Monotypic.
Distribution. SE Bolivia (E Santa Cruz, Chuquisaca and Tarija), W Paraguay (W of R Paraguay), N Argentina E of foothills (S to C Mendoza, S San Luis, S Córdoba and S Santa Fe, and from C Formosa and C Chaco S to S Corrientes and Entre Ríos) and NW Uruguay.

Descriptive notes. 18 cm; 20–25 g. A slim finch with long and relatively wide tail, bill moderately thick at base and with convex culmen and gonys. Male has distinctive face pattern, with forehead and front of face (anterior to eye) black, black continuing down through cheek and bordering white of throat to end on side of neck, pattern further accentuated by bold white posterior supercilium (broadest behind eye, tapering towards nape); small white submoustachial spot at base of lower mandible, narrow but well-defined white lower half of eyering, grey ear-coverts; crown brown, continuing to brownish nape; upperparts pale brown with olive wash, becoming grey on lower back, rump and uppertail-coverts; upperwing similarly brownish, lesser and median upperwing-coverts usually greyish or greyish-brown, flight-feathers and tertials with pale brown edges, greyer on primaries; tail blackish, central feather pair grey, outer rectrices largely white on distal third (creating very obvious white tail corners when in flight, or when seen from below); grey of face continues down to breast side and around blackish "droopy" mask, ending in greyish breastband below white throat; lower pectoral band and side of breast to flanks bright cinnamon-buff; belly, vent and undertail-coverts whitish; iris dark; bill bright yellow, darker culmen; legs dusky. Female is very similar to female, often indistinguishable, but when in direct comparison seen to be slightly duller in coloration, with mask less extensive and paler in colour, also grey of face and breast less vivid. Juvenile is like female, but paler brownish above, and significantly paler on sides and flanks, also bill blackish with dull yellow along cutting edge. Voice. Song, given persistently even through heat of day, a repetitive and simple warble, "vera-vera-vera...". Call a dull-sounding "chup", often doubled as "chu-chup"; other calls include higher-pitched "swiip".
Habitat. Open *chaco* woodland, particularly along road edges, edges of fields and in more open and shrubbier parts.
Food and Feeding. Not well known. Appears to have a mixed diet including insects and seed. Forages both on ground and in low shrubs. Often in pairs or in small mixed flocks with other finches.
Breeding. Season Nov–Mar. Nest a cup of dry grass and fibres, secured to leaves, clump of grass or sometimes small twigs from 20 cm to 1·2 m above ground. Clutch 3 eggs, white with some blackish markings. Commonly parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Largely resident; possibly a partial migrant, as suggested by variation in abundance at N end of range in Bolivia.
Status and Conservation. Not globally threatened. Common to abundant throughout most parts of range. Continues to sing through hottest part of day, which can make it one of the most obvious species, at least acoustically, in its *chaco* habitat.
Bibliography. Armani (1985), Blendinger & Ojeda (2001), Burns *et al.* (2003), Canevari *et al.* (1991), Delhey & Scorolli (2002), Hennessey *et al.* (2003), Klicka *et al.* (2007), Mezquida (2003, 2004), de la Peña (1987), Ridgely & Tudor (1989), Storer (1989b), Wetmore (1926).

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family ICTERIDAE (NEW WORLD BLACKBIRDS)

- Smallish to large passerines with pointed bill, plumage mostly dark, often glossy, many species with bright patches of colour, some richly coloured.
- 16–53 cm.

- New World.
- Forest, mixed woodland, scrub, grassland and agricultural areas, marshes, rocky cliffs and suburban environments.
- 31 genera, 111 species, 259 taxa.
- 14 species threatened; 1 species and 1 subspecies extinct since 1600.

Systematics

The constitution of the family Icteridae has for a long time been subject to many and varying opinions. In 1968, for example, E. R. Blake, in J. L. Peters's *Check-list of Birds of the World*, recognized a total of 91 species in 25 genera. C. G. Sibley and B. L. Monroe, in their 1990 treatment of the world's birds, listed 97 icterid species in 26 genera, whereas A. Jaramillo and P. Burke, in their 1999 monograph of the family, included 103 species in 26 genera. The present treatment recognizes 111 species, divided among 31 genera. The family is commonly referred to as "the New World blackbirds", and includes the caciques, oropendolas, New World orioles, grackles, cowbirds and others.

Since the late nineteenth century, avian taxonomists have come to regard icterids as members of an assemblage of songbirds known as the nine-primaried oscines. This is a large group, in the New World containing the New World warblers (Parulidae), the tanagers (Thraupidae), and many buntings and New World sparrows (Emberizidae). In the 1980s, the status of Icteridae as a family was questioned. Thus, in the classification of the American Ornithologists' Union, in 1983, and that of Sibley and Monroe, in 1990, the group's taxonomic status was downgraded to that of a tribe, Icterini, within a huge family Fringillidae, which comprised all of the nine-primaried oscines.

Icterids form a relatively well-defined group, and there are few disagreements over which species belong to the family. Some authors have regarded the Dickcissel (*Spiza americana*) as an icterid, rather than a cardinal (Cardinalidae), and it has been suggested that the Scarlet-throated Tanager (*Compsothraupis loricata*) could be an icterid and not, as currently considered, a member of the family Thraupidae. Neither of these ideas, however, has gained general acceptance.

The oldest fossil icterids are from the Pleistocene of North America and they give no clues as to the origin of the family. The considerable internal genetic divergence found among the icterids suggests that the family originated around the late Miocene, when North America and South America were separated by an archipelago stretching from present-day southern Mexico south to northern Colombia. This archipelago existed until about 3·5 million years ago, when Central America and the Isthmus of Panama provided a continuous land connection between the two continental masses. Some authors, including E. Mayr, have suggested that Icteridae originated in the North American continent, but others, such as Sibley and J. E. Ahlquist, favour a South American origin. Whatever the case, icterids probably colonized both continents quite early in their evolutionary history, using the Central American or the Caribbean archipelagos as stepping stones. Today, the family is somewhat more diversified in South America than in North America.

Fossil icterids include three extinct genera, *Cremaster*, *Pandanaris* and *Pyelorhamphus*. The first of these consists of the single species *Cremaster tytthus*, described by P. Brodkorb from three leg elements found in Upper Pleistocene sediments of Florida, in the south-east USA. It is supposed to be related either to *Amblycercus* or to *Cacicus*, both genera being absent today from North America. *Pandanaris* is known from Upper Pleistocene deposits of Florida (Reddick) and California (Rancho La Brea), representing the two respective species *Pandanaris floridana* and *Pandanaris convexa*. *Pyelorhamphus molothroides* was described from material in a cave in New Mexico, apparently dating from the late Wisconsin glaciation. The fossil remains of these two genera include maxillae and mandibles indicative of a thick, conical bill. It has been suggested that both *Pandanaris* and *Pyelorhamphus* were generalized blackbirds resembling, and probably related to, modern parasitic cowbirds (*Molothrus*). *Pandanaris floridana* apparently lived in a period cooler than the present one. In addition, 13 extant icterid genera are known from Pleistocene and Holocene deposits, extending from Canada southwards to Brazil, and including the island of Puerto Rico.

The internal subdivisions of the Icteridae are a matter of controversy. Classical taxonomists such as R. Ridgway and C. E. Hellmayr considered that subdivisions would be both arbitrary and impractical. In the early 1950s, a morphological study by W. J. Beecher suggested that cowbirds were the ancestral icterids, and that three lineages evolved from the primitive stock; these were the oropendolas and caciques, the grackles, and the remaining blackbirds, the last including the orioles. Blake, in the 1960s, advanced the idea that the finch-like Bobolink (*Dolichonyx oryzivorus*) was so dissimilar to other icterids that it merited placement in a subfamily of its own. This found some support from the American Ornithologists' Union, which, in its 1983 checklist, recognized three main lineages, one containing just the Bobolink, another incorporating the orioles, caciques and oropendolas, and a third housing the remaining icterids.

More recent molecular studies have been carried by a team consisting of S. M. Lanyon, K. E. Omland and others. These scientists analysed the mitochondrial cytochrome *b* gene of 57 species in 23 of the genera recognized by Sibley and Monroe. A

subsequent study extended the technique to 25 species of oriole, and later to many more. Most of their findings appear robust and plausible, and are often corroborated by morphological and behavioural data. The team identified five lineages of icterids: caciques and oropendolas, orioles, grackles and allies, meadowlarks and allies, and a group containing only the Yellow-billed Cacique (*Amblycercus holosericeus*). Their basic results are followed in the present treatment. Taxonomic problems within the five clades may occur at the generic and specific level.

The Yellow-billed Cacique was left in an uncertain position in the family tree, and doubts were cast even on its classification as an icterid. In its morphology and behaviour, however, this all-black bird with a pale, chisel-shaped bill looks and behaves like an icterid. On the other hand, its peculiar skeletal morphology and cup-like nest suggest that it is highly unlikely to be a cacique, and that it is misnamed as such. Its range extends from Mexico south to Bolivia, it lives in dense vegetation and undergrowth, and it has an extremely wide altitudinal range, occurring from sea-level to as high as 3500 m in the Andes. It is subdivided into three subspecies, which may, in the view of some authors, represent distinct species.

Mitochondrial DNA data indicate that the group consisting of caciques and oropendolas is a natural and monophyletic one. Caciques and oropendolas were traditionally classified in two genera, respectively *Cacicus* and *Psarocolius*. The DNA data, however, support neither a clear-cut division between caciques and oropendolas nor the monophyly of the caciques. In particular, the Solitary Cacique (*Procacicus solitarius*) and the Yellow-winged Cacique (*Cassiculus melanicterus*) are not related to other caciques, but are ancestral to oropendolas. The Yellow-winged Cacique resembles oropendolas in having yellow tail sides, and also in size dimorphism and breeding behaviour, but the all-black, dark-eyed Solitary Cacique certainly does not. The two are placed in separate genera, respectively *Cassiculus* and *Procacicus*. All of the remaining caciques, with the exception of the Yellow-billed, are provisionally retained in *Cacicus*. If the group is to be subdivided, the old generic name *Archiplanus* could be used for three closely related species, namely the Ecuadorian (*Cacicus sclateri*), Selva (*Cacicus koepckeae*) and Golden-winged Caciques (*Cacicus chrysopterus*). The subdivisions and nomenclature of the remaining species are problematic.

Preliminary DNA data reveal that two odd species, the Casqued Oropendola (*Clypicterus oseryi*) and the Band-tailed Oropendola (*Ocyalus latirostris*) of the upper Amazon Basin, are closer relatives of the Red-rumped Cacique (*Cacicus haemorrhous*), and therefore only distantly related to the true oropendolas in the genus *Psarocolius*. There is some corroborative evidence for this finding, as the behaviour and voice of the Band-tailed Oropendola resemble those of Red-rumped Caciques. The external morphology of these two "false" oropendolas is so dissimilar to that of *Psarocolius* that, pending further analyses, they are classified in two monotypic genera, *Clypicterus* and *Ocyalus*. In particular, *Clypicterus* has evolved a swollen casque on its bill, although this somewhat resembles that of the Chestnut-headed Oropendola (*Psarocolius wagleri*). Separation of the two at the genus level is reasonable in terms of morphological change, but from a cladistic perspective it creates complications because the two "false" oropendolas should share the genus of the Red-rumped Cacique, and this last is the type species of the genus *Cacicus*. Some Brazilian authors adhere strictly to cladistic rules and include the two "false" oropendolas in *Cacicus*.

All other oropendolas appear to be clearly monophyletic, and are combined in the genus *Psarocolius*. Although the Chestnut-headed Oropendola has sometimes been separated in a monotypic genus, *Zarhynchus*, such treatment is not supported by the molecular data. Further, all of the large oropendolas with naked facial patches are occasionally segregated in *Gymnostinops*, and, according to DNA data, this group also seems monophyletic; it could, however, be included in *Psarocolius* without forcing the phylogenetic tree, a treatment followed for the sake of nomenclatural parsimony. It would be plausible to use *Gymnostinops* as a subgenus of *Psarocolius*.

The large oropendolas present one of the most persistent taxonomic problems at the species level. At one extreme, it would be possible to recognize just two species, the clear-cut Green Oropendola (*Psarocolius viridis*) from Amazonia and, second, a complex of five different-looking allopatric forms found from the tropical lowlands of Mexico south to lower Amazonia. Three forms occur west of the Andes, these being the Montezuma Oropendola (*Psarocolius montezuma*), the Black Oropendola (*Psarocolius guatimozinus*) and the Baudo Oropendola (*Psarocolius cassini*), which have mostly non-overlapping ranges. The first is rather

*The **Yellow-billed Cacique** occupies an uncertain position within Icteridae, and doubts have been raised as to whether it even belongs in the family. In its morphology and behaviour, this all-black bird with its pale, chisel-shaped bill looks and acts like an icterid, but DNA and skeletal data, and its nest structure, indicate that it is not related to the true caciques. For now,* Amblycercus *is a monotypic genus, but the genetic distance between two of the three races suggests that at least two species may be involved.*

[*Amblycercus holosericeus australis*, Chuspipata, La Paz, Bolivia. Photo: Joe Tobias]

DNA data suggest that there is not a clear-cut division between the caciques and the oropendolas, and also that two species traditionally placed in the cacique genus Cacicus *are not related to other caciques but are ancestral to the oropendolas. The remaining caciques, including the* ***Subtropical Cacique****, are retained in* Cacicus. *The Scarlet-rumped Cacique* (Cacicus microrhynchus) *is often considered to be conspecific with the Subtropical Cacique, and either common name may be used for* Cacicus uropygialis. *The two differ vocally, however, and most authors now treat them as separate species.*

[*Cacicus uropygialis*, Sarapiquí, Costa Rica. Photo: Alex Vargas]

widespread, found from Mexico south to central Panama, whereas the other two have smaller ranges in Panama and the Chocó region of western Colombia. These three trans-Andean forms are usually regarded as three distinct species, as in the present treatment. The Baudo Oropendola differs from the other two in having a pinkish-red, as opposed to pale blue, bare facial patch, thus resembling the Para Oropendola (*Psarocolius bifasciatus*), which occurs far off, around the lower reaches of the Amazon. DNA data are not yet available for testing the relatedness of these two, but if a close relationship is confirmed, the Baudo Oropendola could be the result of a recent colonization from lower Amazonia, or perhaps the relict of a former continuous distribution across northern South America.

The two forms occurring east of the Andes differ strikingly from each other in plumage, but share a pinkish-red facial patch. The widespread Amazonian Oropendola (*Psarocolius yuracares*) is mostly olive-greenish, and extends over most of Amazonia, from Venezuela south to Bolivia. It is replaced only in the lower Amazon Basin by the Para Oropendola, which exhibits a chestnut coloration reminiscent of that of the geographically distant Montezuma Oropendola. The Amazonian and Para Oropendolas are often treated as conspecific, the main reason for uncertainty about their taxonomic status being the existence of intermediate specimens from between the Tapajós and Tocantins rivers, south of the River Amazon. These specimens were formally described by E. Snethlage in 1925 as a new species, under the name *Gymnostinops neivae*. Further specimens with intermediate coloration, mostly chestnut with a variable greenish to olive tinge, and a dusky head, have been collected in this region of Brazil, and on this evidence J. Haffer suggested that the two cis-Andean forms be treated as conspecific. Genetic and behavioural aspects of the interaction between the two, including mating preferences, if any, have not, however, been studied; indeed, even the basic nesting biology of the Para Oropendola remains unknown. Hybridization is not in itself proof of a sister relationship, as illustrated by mitochondrial DNA analysis in a similar case involving North American orioles.

Another pending problem of oropendola systematics concerns the Russet-backed Oropendola (*Psarocolius angustifrons*). In 1937, J. T. Zimmer lumped a string of six, mostly Andean oropendola forms, all with yellow bills, and a black-billed form, the current nominate race, of riparian habitats in western Amazonia. Hellmayr then provided vernacular names for all of the forms of the complex. The six Andean forms, sometimes referred to collectively as the "Yellow-billed Oropendola", extend from northern Venezuela south to central Bolivia, and the Amazonian form, the "Black-billed Oropendola", is found from eastern Colombia south to Peru and western Brazil. Recent fieldwork in the foothills of the eastern Andes of Colombia has revealed that the local form *neglectus*, the "Olive-bellied Oropendola", does not form mixed colonies with the sympatric black-billed nominate race, the two behaving as separate species. Recent DNA studies agree with this finding, as they indicate considerable sequence divergence between the "Black-billed Oropendola" and the four northern Andean forms that range from Venezuela south to Ecuador; moreover, the songs of some of the north Andean forms are distinctive. On the other hand, the DNA divergence between *alfredi*, known as the "Pale-billed Oropendola" or "Alfred's Oropendola", and the "Black-billed Oropendola" was relatively small and the songs of the two are similar, suggesting that they are conspecific. In fact, intermediate-looking specimens are reported from eastern Ecuador.

Although often considered to be conspecific with the Subtropical Cacique (*Cacicus uropygialis*), the Scarlet-rumped Cacique (*Cacicus microrhynchus*) is nowadays treated by most authors as a separate species. Further, it has been suggested that its two subspecies differ vocally from each other and should be regarded as two species, but further research is required before such a decision is taken. Similarly, the two mountain caciques are often combined, but they seem to be sufficiently distinct to be treated as separate species. The Southern Mountain Cacique (*Cacicus chrysonotus*), as well as differing in plumage details from the Northern Mountain Cacique (*Cacicus leucoramphus*), appears to call with a slower, softer series of notes than the latter. A third possible split, a division of the Yellow-rumped Cacique (*Cacicus cela*) into trans-Andean and cis-Andean species, is as yet premature, pending further information on the west Ecuadorian race *flavicrissus*.

The detailed molecular phylogeny presented by Omland and Lanyon supports the view that the American orioles form a mono-

The majority of icterid species have an extended culmen that covers part of the forehead. In some genera, particularly the caciques and oropendolas, this expands into a well-developed casque that may cover the frontal part of the head. Because of its peculiar bill shape, the ***Chestnut-headed Oropendola*** *has sometimes been separated in a monotypic genus,* Zarhynchus. *DNA analysis, however, indicates that it belongs to a clade containing the "mountain oropendolas", the Dusky-green Oropendola* (Psarocolius atrovirens) *and north Andean races of the Russet-backed Oropendola* (P. angustifrons). *The large oropendolas with naked facial patches, such as the* ***Para Oropendola****, are occasionally segregated into the genus (or subgenus)* Gymnostinops. *Five* "Gymnostinops" *species are recognized here, but these large oropendolas present a taxonomic problem at the species level. It would be possible to recognize just two species, the Green Oropendola* (P. viridis) *from Amazonia, and a complex of five different-looking allopatric forms found from the tropical lowlands of Mexico south to lower Amazonia. Two of these five, the Para Oropendola of the lower Amazon Basin and the more widespread Amazonian Oropendola* (P. yuracares), *are often considered conspecific. They share a pinkish-red facial patch. The Amazonian Oropendola is mostly olive-greenish, while the Para Oropendola has a chestnut coloration reminiscent of another member of this species group, the geographically distant Montezuma Oropendola* (P. montezuma).

The genus Icterus *is the largest in the family, with 34 species recognized here. There are many more species in Mexico, Central America and the Caribbean islands than in mainland South America, with just two species in southern South America and none in Chile. Molecular data suggest that there are three lineages within* Icterus. *One contains most of the North American orioles, including many Mexican species. The second holds the troupials, and the third is a lineage of slender-bodied, small-billed orioles found mostly in the Caribbean, Central America and northern South America, such as the* ***Black-cowled Oriole*** *(above) and the* ***Yellow Oriole*** *(below). The Black-cowled Oriole was formerly regarded as the mainland race of what was then called the "Greater Antillean Oriole"* (Icterus dominicensis), *but was separated on DNA evidence. Subsequently, the four island races were also elevated to species status on the basis of mitochondrial DNA and differences in plumage and vocalizations. Females of some oriole species have lost the colourful male-like plumage and are much duller. This dichromatism is strongest in migrant* Icterus *species. In the sedentary Yellow Oriole, the female is similar to the male, though with an olivaceous tinge in yellow areas of the plumage. Females of the apparently resident Black-cowled Oriole, however, are variable: some are dull, some are brighter and more like the male, while some, mainly in the south of the range, are almost identical to the male.*

[Above: *Icterus prosthemelas*, Costa Rica. Photo: Tom J. Ulrich/VIREO.

Below: *Icterus nigrogularis trinitatis*, Trinidad. Photo: George M. Jett]

phyletic group, and all are classified in the genus *Icterus*, the largest in the family. Omland and Lanyon's data suggested the existence of three monophyletic lineages within the orioles. One lineage, clade C, contains most of the North American orioles, including many Mexican species, but excepting the Orchard Oriole (*Icterus spurius*); the second, clade B, holds the troupials; and the third is a lineage of slender-bodied, small-billed orioles, found mostly in the Caribbean, Central America and northern South America. This last lineage, clade A, corresponds quite well with a grouping previously suggested, on the basis of morphological details, by Beecher and sometimes identified by the generic name of *Bananivorus* or *Pendulinus*. A recent molecular study of the orioles, this time involving DNA from the Z sex chromosome, likewise recovered the three oriole clades. The main discrepancy was the position of the little-known Bar-winged Oriole (*Icterus maculialatus*) from the highlands of northern Central America, placed near clade A according to mitochondrial DNA, but near clade C in analysis of the Z chromosome.

These three oriole clades have more species in Mexico, Central America and the Caribbean islands than in mainland South America. Recent molecular data and the use of the "molecular clock" suggest that clade A probably invaded South America from the Antilles around 2 million to 3 million years ago. Perhaps the other two oriole clades are also relatively recent invaders of South America. If this is the case, the scarcity of orioles in southern South America, where only two species occur, with none in Chile, would be an effect of geological time. This idea is reinforced when one compares the rarity of oriole pollination in the flora of Argentina with its frequency in the flora of Mexico.

The species-level taxonomy of the Baltimore Oriole (*Icterus galbula*) and Bullock's Oriole (*Icterus bullockii*) has been subject to many interpretations. The ranges of the two species overlap in the Great Plains of North America, from south Alberta and Saskatchewan, in south Canada, south to Oklahoma and Texas, in the southern USA. The width of the overlap zone varies from 160 km to 240 km, and hybrids and back-crosses are relatively common along this strip. Introgression of heterospecific genes outside the hybridization belt is uncommon, with a tendency for the plumage of Bullock's Oriole to occur farther away from the overlap zone than that of the Baltimore Oriole. Mitochondrial DNA analysis indicates that the species concerned are not sister-taxa. This is an important result, as it shows that hybridization is not an entirely reliable indicator of a close phylogenetic relationship.

Two Mexican orioles with divergent or unusual coloration, the Black-backed Oriole (*Icterus abeillei*) and Fuertes's Oriole (*Icterus fuertesi*), have often been regarded as subspecies of, respectively, Bullock's Oriole and the Orchard Oriole. Mitochondrial DNA data indicate only small genetic distinctiveness in both populations, but the Black-backed Oriole is not closely related to Bullock's Oriole, and is the sister-species of the Baltimore Oriole.

Analyses of mitochondrial DNA have uncovered deep divergences among insular populations of Caribbean orioles, indicating prolonged isolation. Traditional taxonomic treatments combined all orioles found in the Bahamas, Cuba, Hispaniola and Puerto Rico into one species, the "Greater Antillean Oriole", under the name *Icterus dominicensis* (*sensu lato*), usually including also the similar-looking Black-cowled Oriole (*Icterus prosthemelas*) of south Mexico and Central America. Molecular data suggested that this arrangement was incorrect, as the Greater Antillean and mainland taxa were not even sister-species. Within the orioles of the Greater Antilles, the Puerto Rican population, formerly treated as a subspecies, had a sequence divergence of 5·4%, indicating a long period of isolation. Further, DNA data show the Puerto Rican Oriole (*Icterus portoricensis*) to be more closely related to the three oriole species in the Lesser Antilles, which have traditionally been treated as three separate species. In 2005, O. H. Garrido and co-workers reviewed the morphometrics, plumage and vocal characters of the remaining orioles in the Greater Antilles, those in the Bahamas, Cuba and Hispaniola, and advised that each be elevated to the rank of a full species.

Among South American orioles, the taxonomy of the troupials, formerly treated as a single species, has been clarified with the recognition of three species. In this respect, it is relevant to note that, in the state of Pará, Brazil, breeding feral populations of both Campo (*Icterus jamacaii*) and Orange-backed Troupials (*Icterus croconotus*) were present around the city of Belém, but no mixed pairs or intermediate specimens

The ***Cuban Blackbird*** *is sometimes included within the mainland genus* Dives, *with the Melodious Blackbird* (Dives dives) *and Scrub Blackbird* (D. warczewiczi). *Its distinctive skeletal morphology, song and nest-site choice, however, indicate that its placement in the separate monotypic genus* Ptiloxena *is appropriate. According to molecular data, the* Dives *species, along with the Jamaican Blackbird* (Nesopsar nigerrimus), *are the more ancestral members of the "quiscaline blackbirds", the grackles and their allies. The female Cuban Blackbird is like the male, though duller. The male is distinguished from the similar male Shiny Cowbird* (Molothrus bonariensis) *by its much larger size.*

[*Ptiloxena atroviolacea*, Bayamo, Cuba. Photo: Eladio M. Fernández]

The grackles and allies, sometimes called the "quiscaline blackbirds", are represented almost everywhere in the Americas, from the tropics northwards to the arctic tundra, and in the high Andean plateaux up to 4000 m. Quiscalus *grackles have an extremely long, curiously shaped tail. The* ***Carib Grackle*** *was formerly placed in a separate genus,* Holoquiscalus, *with the Greater Antillean Grackle* (Quiscalus niger). *But mitochondrial DNA analysis indicates that the Carib Grackle, which is widespread in the Lesser Antilles and adjacent mainland South America, has a closer relationship with the restricted-range Nicaraguan Grackle* (Q. nicaraguensis) *than with other members of the genus.*

[*Quiscalus lugubris lugubris*, Tobago.

were reported. In contrast is a problematic complex which shows extensive variation in plumage; it is made up of the Epaulet (*Icterus cayanensis*), Moriche (*Icterus chrysocephalus*) and Variable Orioles (*Icterus pyrrhopterus*). Plumage coloration in the complex is essentially black, but the pattern varies from black with small chestnut epaulets to black with contrasting yellow patches on the crown, epaulets, rump and thighs. Hybrids between the two Amazonian taxa, the Moriche and Epaulet Orioles, have been reported from Suriname, possibly explaining why DNA data show that the two forms are paraphyletic. On the other hand, co-existence without hybridization has been reported in Guyana and Brazil, and even, locally, within Suriname. South of the Amazon, there is a group of four taxa, *pyrrhopterus*, *tibialis*, *periporphyrus* and *valenciobuenoi*, connected by extensive areas of intergradation, and traditionally treated as subspecies of the Epaulet Oriole. DNA data suggest a modest amount of genetic divergence, 1·1%, and no paraphyly between the Amazonian and southern groups. In addition, the southern forms share smaller size, a slender body shape and markedly acrobatic foraging habits. As a result of all this, they are now combined in a separate species, the Variable Oriole.

The grackles and their allies, sometimes referred to as the "quiscaline blackbirds", are the most numerous and diverse of the icterids. The group is represented almost everywhere in the Americas, from the tropics northwards to the arctic tundra and in the high Andean plateaux up to 4000 m. According to the molecular data, the more ancestral members of this group are the genera *Nesopsar* and *Dives*, with a mainly Caribbean and Central American distribution. The Jamaican Blackbird (*Nesopsar nigerrimus*) is a very specialized icterid, representing perhaps an earlier radiation within the grackle group; DNA data reveal that it lacks close living relatives. The Cuban Blackbird (*Ptiloxena atroviolacea*) is sometimes included within the mainland genus *Dives*, though on rather weak grounds. Although no DNA data are available, this species' distinctive skeletal characters provide, according to M. S. Webster, a strong argument against this treatment, and its considerable vocal differences support its placement in the monotypic genus *Ptiloxena*.

In a detailed study of skeletal characters in 1991, M. Björklund found that the genus *Quiscalus* was not monophyletic, whereas the 1999 molecular-genetic study by K. P. Johnson and Lanyon provided strong support for the monophyly of the genus. More recently, in 2008, A. F. L. A. Powell and co-workers undertook a detailed examination of *Quiscalus*, together with its sister-genus *Euphagus*, based on an analysis of mitochondrial DNA gene sequences of cytochrome *b* and ND2, in order to reconstruct the relationships within this group of icterids. They found that the two genera composed a clade within the Icteridae. Unlike earlier analyses, that by Powell and colleagues included two grackles with very small geographical ranges, namely the extinct Slender-billed Grackle (*Quiscalus palustris*) of the Valley of Mexico, last recorded in 1910 (see Status and Conservation), and the Nicaraguan Grackle (*Quiscalus nicaraguensis*). The results indicated that the Slender-billed Grackle was closest to one of two major haplotype clades of the Great-tailed Grackle (*Quiscalus mexicanus*), the other being sister to the Boat-tailed Grackle (*Quiscalus major*). The Nicaraguan Grackle appeared to be sister to the Carib Grackle (*Quiscalus lugubris*).

The molecular phylogeny of Lanyon and colleagues has indicated that all parasitic cowbirds share a common ancestor and should be placed together in the single genus *Molothrus*. This applies equally to the Giant Cowbird (*Molothrus oryzivorus*), which was once known as the "Rice Grackle" and classified in genus of its own, *Psomocolax* or *Scaphidura*. Webster found considerable skeletal peculiarities in Giant Cowbirds, which in some characters were close to caciques and oropendolas. Allometric changes related to the large size of the Giant Cowbird, evolutionary convergence of host and parasite owing to the chicks of the two growing in the same nest, and mimicry may, however, be responsible for the similarity. The taxonomic status of only one cowbird has been questioned. This is the Bronze-brown Cowbird (*Molothrus armenti*), isolated in Caribbean Colombia, and usually treated as a distinctive subspecies of the Bronzed Cowbird (*Molothrus aeneus*). It differs from the latter, however, in its smaller size, in its dark brown, rather than black, plumage coloration and in its reduced sexual dichromatism, as well as being vocally distinct.

According to molecular data, the marsh blackbirds traditionally included in the genus *Agelaius* should be separated into a North American and Caribbean lineage and two South American lineages. Similarities between Nearctic and Neotropical species are attributed to convergent evolution. The generic name *Agelaius*

Bright iris coloration in the icterids is usually due to specific pigments, but the red irides of the Bronzed Cowbird, known also as the Red-eyed Cowbird, are coloured by red blood cells. The ***Bronzed Cowbird*** *and the Giant Cowbird* (Molothrus oryzivorus) *were each formerly placed in other genera, but molecular-genetic evidence suggests that all the parasitic cowbirds share a common ancestor and should be placed together in the single genus* Molothrus. *Mitochondrial DNA indicates that they belong with the North American quiscalines, even though molecular data suggest that the Screaming Cowbird* (M. rufoaxillaris), *a South American species, is possibly the oldest extant species.*

[*Molothrus aeneus loyei*, Pima County, Arizona, USA. Photo: Brian E. Small]

belongs to the North American and Caribbean clade, while the South American lineages have the generic names *Agelasticus* and *Chrysomus*. *Agelaius* blackbirds include one widespread species, the Red-winged Blackbird (*Agelaius phoeniceus*), and four similar species with smaller ranges in California and the Caribbean. Molecular analysis of Red-winged Blackbird populations shows that the species' geographical expansion is rather recent, and that most of its huge range was occupied only in postglacial times. A controversial form of this species is the subspecies *gubernator*, found in wetlands on the Mexican plateau; this is sometimes treated as a separate species under the name of "Bicolored Blackbird", but is now believed to hybridize with several northern races. The "bicolored" male plumage also occurs in two Californian races but their female plumages are quite different from those of the Mexican birds. The five South American blackbirds formerly included in *Agelaius* are more diverse in appearance than the five North American ones, having only one species in which the male is all black except for contrasting epaulets. Molecular data sug-

Molecular data indicate that the "marsh blackbirds" traditionally included in the genus Agelaius *should be separated into a North American and Caribbean lineage and two South American lineages. The generic name is retained for the five species of the North American/ Caribbean clade, including the* ***Tawny-shouldered Blackbird****. The South American species are now divided between two genera, the stocky, thick-billed* Chrysomus *and the slender, thinner-billed* Agelasticus.

[*Agelaius humeralis humeralis*, Najasa, Cuba. Photo: Zhao Chao]

*The **Velvet-fronted Grackle** gets its name from the feathers on its forehead and lores, which are stiff and plush-like. Five subspecies are recognized, at least two of which, the "Bolivian Grackle"* (boliviensis)*, shown here, and the "Violaceous Grackle"* (violaceus)*, may merit full species status. Where its range overlaps with that of the Carib Grackle* (Quiscalus lugubris)*, the Velvet-fronted Grackle can be distinguished by its smaller size, smaller bill, drabber coloration, tail shape, more pleasant song and other vocalizations, and dark brown eye colour.*

[*Lampropsar tanagrinus boliviensis*, near Trinidad, Beni, Bolivia. Photo: Daniel Alarcón]

gest that the five Neotropical species fall into two clades. One of these, the genus *Chrysomus*, contains two thick-billed and stocky species, apparently more granivorous than insectivorous, the males of which do most of the nest-building work. The three other species, now placed in *Agelasticus*, share a rather slender form and a thinner bill, and are more typical icterids in that it is the females that undertake the task of nest-building.

The two robust brown-and-yellow species of *Pseudoleistes* with the rather insipid English name of "marshbirds", together with the Saffron-cowled Blackbird (*Xanthopsar flavus*), form another group of Neotropical quiscalines, possibly related to *Chrysomus*. DNA data indicate that the Saffron-cowled Blackbird, formerly placed in *Agelaius*, is closer to *Pseudoleistes*. Because of its smaller size, distinctive slender form, sexual dichromatism and voice, it is placed in the monotypic genus *Xanthopsar*.

Four other genera of Neotropical quiscaline icterids are found in woodlands and savanna. These are *Gnorimopsar*, *Oreopsar*,

Analysis of mitochondrial DNA suggests a relationship between the morphologically very different Velvet-fronted Grackle (Lampropsar tanagrinus)*, above, the Red-bellied Grackle* (Hypopyrrhus pyrohypogaster) *and the **Oriole Blackbird**. The female Oriole Blackbird shares the male's highly distinctive chrome-yellow and black plumage, and both sexes sing. The male and female of the Red-bellied Grackle are also similar in appearance. Females of all three of these related species are slightly smaller than the males, but with nothing like the size disparity found in some* Quiscalus *species, which can be greater than 50%.*

[*Gymnomystax mexicanus*, Llanos, Venezuela. Photo: Jean-Louis Le Moigne/NHPA]

Curaeus and *Agelaioides*, which contain a total of six species with mostly plain black or brown plumage. The bill shape of these genera is somewhat variable, ranging from finch-like, in the genus *Agelaioides*, to elongate, as in *Curaeus*. All are rather generalist, gregarious icterids exhibiting some behaviour patterns that are unusual in the family, such as hole-nesting, except for *Curaeus*, and various degrees of co-operative breeding. The genus *Curaeus* has an oddly disjunct distribution, with one species in tropical east Brazil and the other in the southern-temperate region of South America. The tropical form is the rare Forbes's Blackbird (*Curaeus forbesi*), formerly regarded as a species of *Gnorimopsar* or *Agelaius*, and even as an intergeneric hybrid between the former and *Chrysomus*. Its present position in *Curaeus* is based mostly on bill shape, no molecular data being available. The two baywings constituting the genus *Agelaioides* have the most drab and inconspicuous coloration of any member of the family. The Pale Baywing (*Agelaioides fringillarius*), confined to north-east Brazil, is often treated as a subspecies of the more widespread Greyish Baywing (*Agelaioides badius*), but differs significantly in its vocalizations; it is probably better regarded as a separate species. Mitochondrial DNA data suggest a close relationship between *Agelaioides* and the monotypic *Oreopsar*, which possibly should be merged, but they are retained as separate genera pending an analysis of the Pale Baywing. Molecular data indicate, unexpectedly, that the Scarlet-headed Blackbird (*Amblyramphus holosericeus*) is related to *Curaeus*. This finding is somewhat controversial, because the Scarlet-headed Blackbird is one of the most colourful members of the family; is unusual in its very specialized diet and bill shape; and lives mostly as scattered territorial pairs in marshes.

The final lineage of Neotropical quiscalines is a heterogeneous and not well-known group that includes the two mountain grackles (*Macroagelaius*), the Velvet-fronted Grackle (*Lampropsar tanagrinus*), the unusual Oriole Blackbird (*Gymnomystax mexicanus*) and the Red-bellied Grackle (*Hypopyrrhus pyrohypogaster*). Molecular data suggest that these four genera are related, but it is not clear how close the affiliation is. Forbes's Blackbird, tentatively included within *Curaeus*, but without DNA data, could alternatively fit into this group.

The meadowlarks and allies comprise just ten species, all found in open environments, mostly grassland and marshes. A very odd member of the meadowlark clade is the Yellow-headed Blackbird (*Xanthocephalus xanthocephalus*), a large North American marsh blackbird in the monotypic genus *Xanthocephalus*. It was formerly thought to be related to *Agelaius*, although the behavioural comparisons made by G. Orians and J. Christman in 1968 revealed that Yellow-headed Blackbirds' displays were different from those of Nearctic *Agelaius* species. The isolated taxonomic position of this icterid suggests that it may be a surviving member of a past Nearctic radiation of the meadowlark clade.

According to molecular data, the Bobolink, a grassland species remarkable for its long migratory flights between North America and South America (see Movements), is related, albeit only distantly, to the meadowlark clade. This is plausible, as the Bobolink resembles the smallest Neotropical meadowlarks, namely the Red-breasted (*Sturnella militaris*) and White-browed Blackbirds (*Sturnella superciliaris*), in its nest architecture, ecology and behaviour, in its elongate tertial feathers, and even in its non-breeding plumage.

All eight species of meadowlark are terrestrial, long-billed and stocky icterids. The genus is represented in all mainland American countries, but is absent from many Caribbean islands. No other icterids are more adapted for living in meadows, grasslands and steppes, sometimes in semi-desert country. The smallest species in the group, the Red-breasted and White-browed Blackbirds, were formerly separated in the genus *Leistes*. In 1968, however, L. L. Short reviewed the taxonomy of the group and suggested that all the species be combined in a single genus, because *Leistes* was connected to the "typical" meadowlarks by intermediate species such as the Pampas Meadowlark (*Sturnella defilippii*), and shared many morphological and behavioural traits with them. Short's views have been supported by recent analyses of mitochondrial DNA. This taxonomic change meant that the taxon hitherto named *Pezites militaris* would have become *Sturnella militaris*,but this combination was not applicable for this species, as it was preoccupied. Consequently, the Long-tailed Meadowlark (*Sturnella loyca*) took on its current nomenclature, using the next available name.

Meadowlark taxa having a yellow breast are usually grouped into two very similar species, the Eastern Meadowlark (*Sturnella magna*) and the Western Meadowlark (*Sturnella neglecta*), which

The genus Curaeus *has an oddly disjunct distribution, with one species, Forbes's Blackbird* (Curaeus forbesi), *in tropical east Brazil and the other, the* ***Austral Blackbird****, in the southern-temperate region of South America. Forbes's Blackbird was placed in this genus because its bill shape is similar to that of the Austral Blackbird, but no DNA data are available. Two races of the Austral Blackbird are recognized. A third has been proposed, based upon a supposedly slightly recurved bill on birds from Riesco Island, off southern Chile, but recent observers have not reported peculiarities in bill shape.*

[*Curaeus curaeus curaeus*, Melipilla, Chile. Photo: Manuel Marín]

The genus Agelasticus *is often subsumed in* Agelaius *or* Chrysomus. *Mitochondrial DNA analysis indicates that the relationship of the* ***Yellow-winged Blackbird*** *to its two congeners is not close. It differs also in certain ecological, vocal and plumage characteristics, and has been considered for its own genus. A highland subspecies of the Yellow-winged Blackbird,* alticola, *regularly nests around the shores of Lake Titicaca, at 3810 m above sea-level. No other icterid has been recorded at such high elevations.*

[*Agelasticus thilius petersii*, Lagoa dos Patos, Tavares, Rio Grande do Sul, Brazil. Photo: Edson Endrigo]

differ from each other mostly in vocalizations. J. C. Barlow, S. A. Rohwer and other ornithologists, using morphological and vocal data, argued that there existed a third species, Lilian's Meadowlark (*Sturnella lilianae*), which has usually been treated as a desert-adapted subspecies of the Eastern Meadowlark. Recent DNA data support the elevation of *lilianae* to full species rank. Further, the Eastern Meadowlark has a good number of distinctive subspecies in the Caribbean and the northern Neotropics. DNA research has indicated a significant genetic divergence of the Cuban subspecies *hippocrepis*, suggesting a long isolation, and further information will perhaps show that this taxon, too, merits treatment as a full species.

Morphological Aspects

Icterids range in total length from about 15 cm to 53 cm, and in body mass from 20 g to approximately 560 g. The variation in body size found among icterids well exceeds that of closely related families such as the New World warblers or the tanagers.

Most icterids exhibit sexual size dimorphism, the males being larger and heavier than the females. Extreme cases of size dimorphism occur with most oropendolas, and also in the Boat-tailed and Great-tailed Grackles. In the case of the Montezuma and Crested Oropendolas (*Psarocolius decumanus*), the female's mass is, respectively, 47% and 56% of that of the male; for the

The two Pseudoleistes *marshbirds are closely related and very similar in appearance. The* ***Brown-and-yellow Marshbird*** *differs from the Yellow-rumped Marshbird* (Pseudoleistes guirahuro) *in its browner and less colourful appearance, and its brown rump. Both are highly social species, which breed co-operatively. With these species, group singing is far more frequent than solo singing. DNA data indicate a close affinity between the marshbirds and the Saffron-cowled Blackbird* (Xanthopsar flavus). *The Saffron-cowled Blackbird is, however, smaller and less robust, with strongly marked sexual dichromatism. The marshbird sexes are similar to each other.*

[*Pseudoleistes virescens*, Buenos Aires, Argentina. Photo: Juan María Raggio]

The two baywings of the genus Agelaioides *have the most drab and inconspicuous coloration of any member of the family. The* ***Greyish Baywing*** *(left) and the* ***Pale Baywing*** *(right) have often been treated as conspecific, with the latter regarded as a race of the more widespread Greyish Baywing. As well as in plumage, however, they differ in vocalizations and some details of social behaviour.*

[Left: *Agelaioides badius badius*, São Lourenço do Oeste, Santa Catarina, Brazil. Photo: Rudimar Narciso Cipriani.

Right: *Agelaioides fringillarius*, Hotel Fazenda Pai Mateus, Cabaceiras, Paraíba, NE Brazil. Photo: Luiz Claudio Marigo]

two grackles, the corresponding value is about 54–62%. With all of these species the male is strongly polygynous, defending a harem of nesting females. Sexual size dimorphism is probably a result of strong sexual selection, either because females choose the largest males or because the largest males are dominant and exclude the smaller males from mating, or for both reasons.

The members of this family have a strong conical bill, often sharply pointed, and ranging from short and finch-like to elongate. The pointed bill and associated muscles constitute the basic tools for gaping, a typical foraging technique of icterids (see Food and Feeding). Bill deformities are relatively frequent among the Icteridae, and may be due to genetic or developmental factors, injury or disease. The type of a species described by the French naturalists N. F. de Lafresnaye and A. d'Orbigny as "*Icterus maxillaris*" involved a specimen with a bill deformity.

The majority of icterid species have an extended culmen that covers part of the forehead, in some genera expanding into a frontal casque. On many, particularly the caciques and oropendolas, the casque is well developed and may cover the frontal part of the head. The most highly developed casque is found in the monotypic genus *Clypicterus*, the Casqued Oropendola. The basic function of this conspicuous structure is not well known, but it is possibly used in displays.

Crests or elongated head feathers are possessed mostly by oropendolas, and also by the Yellow-winged Cacique, the latter more related to oropendolas than to true caciques (see Systematics). Naked facial areas are present on large oropendolas of the "*Gymnostinops* group" (see Systematics). An extremely long tail, curiously keel-shaped or boat-shaped, has evolved in the *Quiscalus* grackles, particularly the Boat-tailed and Great-tailed Grackles, while the Giant Cowbird male has a conspicuous erectile ruff that he displays to females. Males of these icterids are polygynous, and their "ornamental" features are believed to have evolved through sexual selection.

The predominant plumage colour in the family is black, often with a gloss or iridescence in shades of purple, blue and green. Other plumage colours regularly present include yellow, orange, red, white, and shades of brown and green; blue is absent. Colourful shoulder patches have evolved independently in several icterid genera. In addition, both sexes of all *Psarocolius* oropendolas and of the Yellow-winged Cacique have extensive yellow tail patches. The patches are particularly visible when oropendolas are flying away, and may work as signals to maintain flock cohesiveness, notably useful for fledglings and dependent juveniles. Yellow tail patches have evolved also in the unrelated genera *Clypicterus* and *Ocyalis*, and these could perhaps be examples of social mimicry.

Recent advances in technology have enabled researchers to detect invisible ultraviolet coloration in the plumage of many birds. The most interesting discovery among icterids is the existence of ultraviolet patches in the crown and supercilium of the male Pale-eyed Blackbird (*Agelasticus xanthophthalmus*), the head of which appears solidly black to the human eye. Cryptic coloration, or camouflage, is present particularly in the dorsal plumage of meadowlarks, an icterid group adapted to a terrestrial life in grassland and steppe.

Extensive molecular research undertaken on the genus *Icterus* has resulted in a phylogenetic tree that shows some interesting results as regards the evolution of coloration in the group. Although there is an overall agreement between colour patterns and phylogenetic placement, several cases of colour reversal and convergent evolution in plumage are apparent. Perhaps some parallel changes in sympatric orioles also reflect mimicry of some sort.

Sexual dimorphism in coloration, possibly better named as sexual dichromatism, occurs in many icterids, the females often being far less colourful or more cryptic than the males. Sexual dichromatism is evident particularly among the quiscalines and the meadowlarks, and also some orioles, but is absent or far less obvious among oropendolas and caciques. It may be thought to be the result of sexual selection for colourful plumage in males, but the sum of evidence for this idea is weak. In the case of the polygynous oropendolas and caciques, the sexes are similar in plumage. Sexual dichromatism is found among polygynous quiscalines, but also among monogamous ones. With orioles, marked dichromatism is more frequent among migratory Nearctic species, but any association between migration and dichromatism is weakened by the situation with the Montserrat Oriole (*Icterus oberi*), a strongly dichromatic species confined to a small tropical island.

With some quiscalines, such as the Unicolored Blackbird (*Agelasticus cyanopus*), the Red-winged Blackbird and the Shiny Cowbird (*Molothrus bonariensis*), sexual dichromatism varies geographically, and the sex that exhibits the greater degree of intraspecific variation is the female. Female Unicolored Blackbirds can be strikingly different from the all-black males, sometimes having colourful yellow underparts, or they can be much more male-like. Female Shiny Cowbirds are usually dark brown, but occur also in a male-like morph, "*melanogyna*", which is black like the male, though lacking the male's strong purplish gloss.

*The **Bolivian Blackbird** can be found in mixed flocks including both the Greyish Baywing* (Agelaioides badius) *and the Chopi Blackbird* (Gnorimopsar chopi). *Its calls are reminiscent of those of both. In general aspect, skeletal morphology and behaviour, it resembles the Chopi Blackbird, but mitochondrial DNA data indicate that it could be a sister-species to the Greyish Baywing.* Oreopsar *should possibly be merged with* Agelaioides, *but is retained as a monotypic genus pending an analysis of the Pale Baywing* (A. fringillarius).

[*Oreopsar bolivianus*, near Cochabamba city, Bolivia.
Photo: Daniel Alarcón]

This fact suggests that selection in females may play an important role in the evolution of sexual dichromatism. A similar trend occurs within the five blackbird species in the genus *Agelaius*. The males of all five are invariably black with contrasting colourful epaulets. Females of the two polygynous species lack epaulets and are mostly brownish and streaked, somewhat cryptically coloured; in the three Caribbean, monogamous species, however, the females are black and may even show epaulets.

A recent phylogenetic analysis by C. Hoffman and co-workers, based on sexual dichromatism among orioles, also stresses the particular importance of evolutionary changes in the female plumage. In some oriole species, females have lost the colourful male-like plumage and are much duller. A drab olivaceous plumage would make the females more cryptic and probably reduces predation. The existence of seasonal dichromatism lends some support to this theory. Seasonal dichromatism occurs among males of migratory Nearctic icterids such as the Bobolink and in some orioles, whereby males in the non-breeding season assume a cryptic or drab female-like plumage.

Few passerine families surpass Icteridae in variability of iris colour. The eyes of icterids can be bright blue, almost white, yellow or red, in addition to the usual brownish hues. Within a given species, iris colour may change with sex and age. The subject has not been systematically studied, but eye colour is probably important in social communication. In their small area of range overlap, in the south USA, Boat-tailed and Great-tailed Grackles are best told apart by eye colour. Geographical variation in iris colour has been reported for some icterids, examples being the Russet-backed Oropendola, Boat-tailed Grackle and Giant Cowbird. Bright iris coloration is usually due to specific pigments, namely purines and pteridines, but the red irides of the Bronzed Cowbird, known also as the Red-eyed Cowbird, are coloured by red blood cells.

Some ornithologists have reported that icterids give off a strong or unpleasant smell. According to H. Sick, oropendolas have a smell suggestive of cockroaches (Blattodea), apparently emanating from the uropygial gland. E. Schäfer reported that Venezuelan oropendolas had an odour like that of musk; he further reported that his retrieving dog picked up specimens of the Russet-backed Oropendola subspecies *oleagineus* with visible reluctance. The subject requires a detailed research study.

With one exception, adult icterids undergo a single, complete annual moult, which takes place after the breeding season. The exception is the Bobolink, which has two complete moults, a post-breeding one and a pre-breeding one. The male of this species is notable for the fact that it has two distinct plumages, one a striking black-and-white breeding plumage and the other a very different brown and streaky non-breeding plumage, the latter similar to that of the female. In contrast, the majority of the family

*Unlike all other icterids, which have a single annual moult, the **Bobolink** has two complete moults, post-breeding and pre-breeding. The male's breeding plumage is shown here; in its streaky brown non-breeding plumage, it resembles the female. The finch-like Bobolink is so dissimilar in many respects to other icterids that it was once considered for a subfamily of its own. In its nesting habits and some other aspects of behaviour and morphology, it resembles smaller members of the meadowlark genus* Sturnella. *Cytochrome-b sequence data show that it is closer to* Sturnella *and the Yellow-headed Blackbird* (Xanthocephalus xanthocephalus) *than to other members of the family.*

[*Dolichonyx oryzivorus*, Ontario, Canada.
Photo: Glenn Bartley]

acquire their brighter-looking breeding appearance as a result of the abrasion of the greyish, buffish or olive feather tips of the fresh plumage. Contrary to earlier opinions, the Rusty Blackbird (*Euphagus carolinus*) has recently been found to have a partial pre-breeding moult, involving the feathers of the head. Although some other icterids, such as female Red-winged Blackbirds and some grackles, undergo a similar partial pre-breeding moult of varying extent, it is thought very unlikely that this strategy is used by more than a very few icterids.

An interesting aspect of moult is the way in which the tail feathers are replaced. Most passerines shed the tail feathers centrifugally, from the central pair outwards, but about half of the Icteridae shed theirs centripetally, replacing the outer rectrices first and then progressing inwards. Only the caciques, the oropendolas, the orioles and the Bobolink exhibit the "traditional" centrifugal moult of the tail. *Quiscalus* grackles often shed their tail feathers more or less simultaneously, so that individuals can appear tail-less for a couple of weeks after the end of the breeding season. This phenomenon is sometimes exhibited also by some other members of the family.

Habitat

There are no icterids adapted to the treeless tundra, the extreme deserts or the highest mountains above 4500 m, although in South America families containing more species, such as the tyrant-flycatchers (Tyrannidae) or the ovenbirds (Furnariidae), can be found in some of those biomes. Nevertheless, Icteridae, a family of 111 species, is represented in most habitats in the Americas, sometimes surpassing the closely related tanagers and New World warblers in this respect. Another characteristic of most icterid species is a relative lack of specialization, and a considerable plasticity, in habitat choice. For instance, although mangroves are an important habitat for several icterids, particularly the grackles, there are no species specialized on or confined to this biome. Exceptions to this rule are noted below.

The geographical distribution of the family was summarized by P. Lowther. Four areas in the Americas have the highest numbers of icterid species. Within Canada and the USA the maximum diversity is reached in the central prairies. In Mexico, there is a concentration of species in the southern state of Oaxaca. In Colombia, a high diversity of icterids is present in the Cordillera Oriental. Lastly, the Río de la Plata basin, extending from Paraguay and north-east Argentina east to south-east Brazil and Uruguay, holds up to 21 species. In the middle of this extensive basin, the Argentinian province of Corrientes has 20 species of icterid. Two main biogeographical units in South America, the *cerrado* and the Atlantic Forest, both centred in eastern Brazil, have few

Meadowlarks with a yellow breast are usually grouped into two very similar species, the Eastern Meadowlark (Sturnella magna) *and the Western Meadowlark* (S. neglecta), *which differ mostly in vocalizations.* ***Lilian's Meadowlark*** *was formerly considered a race of the Eastern Meadowlark, but differs in having a shorter tail with a distinctive pattern formed by the white outer rectrices. Its vocalizations are also different. DNA data revealed a deep genetic divergence, supporting* lilianae*'s treatment as a separate species. Some Eastern Meadowlark races may belong with Lilian's Meadowlark, while* S. m. hippocrepis, *the "Cuban Meadowlark", also shows a significant genetic divergence and may merit species rank.*

[*Sturnella lilianae*, Hereford, Arizona, USA. Photo: Charles W. Melton]

The smallest Neotropical meadowlarks, the ***White-browed Blackbird*** *and the Red-breasted Blackbird* (Sturnella militaris), *were previously placed in a separate genus,* Leistes. *The two share many behavioural and morphological traits with the "typical" meadowlarks, however, and are connected with them by intermediate species such as the Pampas Meadowlark* (S. defilippii). *DNA data support their inclusion in* Sturnella. *The two are sometimes considered conspecific, but their ranges overlap in south-east Peru, north-east Bolivia and north-east Brazil with no evidence of interbreeding.*

[*Sturnella superciliaris*, Area Natural de Manejo Integrado San Matías, SE Santa Cruz, Bolivia. Photo: Daniel Alarcón]

*Most icterid species are gregarious, and even those that breed as solitary pairs may form flocks outside the breeding season. The **Yellow-hooded Blackbird** nests colonially and is usually found in small groups. Non-breeding birds, however, can form flocks of several hundreds. The flock sizes of Neotropical icterids never rival those of North American species such as the Red-winged Blackbird* (Agelaius phoeniceus)*, below, which can contain hundreds of thousands of individuals. Although largely resident, flocks of Yellow-hooded Blackbirds may make local movements when the dry season renders their marsh habitat unsuitable.*

[*Chrysomus icterocephalus icterocephalus*, Cayenne, French Guiana. Photo: Tanguy Deville]

icterid species. As both regions have high biodiversity scores for other oscine groups, such as tanagers, this anomaly requires some explanation.

The various subdivisions of the Icteridae have different geographical ranges and centres of diversity. Caciques and oropendolas are tropical to subtropical, occurring from Mexico south to central Argentina, and reaching their highest diversity in western Amazonia and the nearby Andes. The most remote island colonized by the group is Tobago, separated from the nearest land by a sea channel 42 km wide. Caciques and oropendolas are absent from all the main Caribbean islands; possibly their larger size and their arboreal habits make them unsuccessful overseas colonists. The oriole genus *Icterus* is particularly diverse in Mexico and northern Central America, and has successfully colonized several Caribbean islands. Orioles live in xeric to humid habitats, but are poorly represented, with just two species, in southern South America; no members of this group occur in Chile or Patagonia. It is probable that orioles entered South America later than other icterids, as suggested by the results of recent DNA studies. The remaining icterid subclades, namely the grackles and allies and

*The global population of the **Red-winged Blackbird** is estimated at a minimum of 200 million, making it probably the most numerous bird in North America. Flocks can be correspondingly large; in winter, congregations of millions of birds have been reported, mixed with other blackbirds and grackles. These winter flocks can include birds from a number of different breeding populations. Outside the breeding season, flocks can be of a single sex. Although they use the same roost sites, males and females may be segregated at roosts, arriving and leaving separately.*

[*Agelaius phoeniceus fortis*, Bosque del Apache National Wildlife Refuge, New Mexico, USA. Photo: Dave Maslowski/ Maslowski Productions]

the meadowlarks, are more evenly distributed in both the Nearctic and the Neotropics, being found in tropical to cool-temperate biomes. Both icterid subgroups have successfully colonized relatively distant islands, such as the Lesser Antilles and the Falklands, but not the Galapagos or the Juan Fernández archipelagos.

In North America, the most northerly icterid, the migratory Rusty Blackbird, breeds in the boreal coniferous and mixed forests of Alaska, Canada and the extreme north-eastern USA. Its northernmost localities, north of the Arctic Circle, are the Kotzebue Sound and the Mackenzie Delta. This blackbird nests in clearings, marshes and bogs within the forest. The tundra biome, north of the tree-line, lacks native icterids. The moist deciduous woodlands of eastern North America are the summer quarters of the Baltimore Oriole, and similar environments in western North America are the main habitat of Bullock's Orioles. Both oriole species are found mostly in the canopy. Open areas east of the Rocky Mountains are inhabited by Common Grackles (*Quiscalus quiscula*), while Brewer's Blackbirds (*Euphagus cyanocephalus*) breeds in similar habitat also west from the mountains. Both species can be found in very open woodland. Brewer's Blackbird has the highest altitudinal records for Nearctic icterids, having been recorded at up to 3300 m.

Boat-tailed Grackles live in tidal marshes along the coast of the eastern USA. Subtropical and tropical sea coasts are the usual environment of Great-tailed Grackles, which frequent estuaries, brackish lagoons and mangrove swamps. On the tiny coralline islands of San Blas, near the Caribbean coast of Panama, the latter species was found to be the only land passerine present; here, it fed mostly on human refuse, and its nesting sites were in coconut palms (*Cocos nucifera*). Other grackles frequent many types of marshland in the interior of Mexico and Central America, although, in Mexico, the Slender-billed Grackle is now, sadly, extinct (see Status and Conservation). The Nicaraguan Grackle, however, still survives around the lakes and rivers of south-west Nicaragua and adjacent north Costa Rica.

Tropical and subtropical forests are the main biome of most caciques and oropendolas. Forests in Amazonia are traditionally classified into floodplain-forest, represented by *várzea* and *igapó*, and upland forest, or *terra firme*. The *várzea* environment is seasonally flooded by sediment-rich rivers flowing from the Andes, examples being the Putumayo, Napo, Ucayali and Madeira Rivers. *Várzea* soils are the most fertile in all Amazonia, but they occupy only 60,000–65,000 km², less than 1% of the huge Amazon Basin. Many peculiar species of plant occur there and nowhere else. The *igapó* formations are subject to more permanent floods, but from nutrient-poor black-water rivers flowing from the Guianan or the eastern Brazilian highlands, the Rio Negro being a typical example. *Terra firme* forests, the most extensive in Amazonia, are not subject to seasonal flooding.

In Amazonia, Band-tailed Oropendolas use mostly *várzea* forest, whereas Green Oropendolas are more restricted to *terra firme*. Some Amazonian marsh icterids, such as the Yellow-hooded Blackbird (*Chrysomus icterocephalus*) and the Oriole Blackbird, favour mainly the lush grasslands and scrub of the *várzea* and avoid the *igapó* marshes and islands. In contrast, Velvet-fronted Grackles seem to prefer the flooded woodlands along black-water rivers.

Caciques and oropendolas exploit the forest canopy and the upper strata for foraging, but will sometimes descend to ground level or almost so. Colonial-nesting species, including the Yellow-rumped and Red-rumped Caciques and many oropendolas, would seldom nest in unbroken forests, except in large clearings or along rivers. Of all the main forest areas in the Neotropics, only the Atlantic Forest of eastern Brazil and neighbouring countries is poor in icterids, with usually the Red-rumped and Golden-winged Caciques as the only representative of the family.

Other icterids inhabiting tropical forest include the Jamaican Blackbird, many Caribbean orioles, and the mountain grackles of the northern Andes and the Guianan highlands (tepuis). The Jamaican Blackbird is one of the most specialized of all icterids, as it forages mostly in epiphytic bromeliads in wet mountain forest.

The Andean subtropical forests are used by fewer oropendola species, but many specialized solitary caciques occur in this environment. In the Andes, the Yellow-billed Cacique, an inappropriately named species (see Systematics), is found mostly in bamboo thickets. Tropical savannas are the home of several icterids, such as the Melodious Blackbird (*Dives dives*) in the pine (*Pinus*) savannas of Honduras and Nicaragua, and the Oriole Blackbird in the *llanos* of the River Orinoco. Chopi Blackbirds (*Gnorimopsar chopi*) are found in the humid *chaco* savannas, often in palm groves, and are one of the few members of the family that can be seen in the *cerrado* savannas of central

Except for a few that live as territorial pairs, icterids roost communally, and several species may roost together. In studies in the eastern USA, the ***Common Grackle*** *appeared to function as the nucleus in the formation of roosting congregations. The grackles occupied the roost-sites first, and Red-winged Blackbirds* (Agelaius phoeniceus), *Brown-headed Cowbirds* (Molothrus ater) *and two non-icterids commonly found sharing roosts, the Common Starling* (Sturnus vulgaris) *and American Robin* (Turdus migratorius), *joined later. In late summer, Common Grackles often roost in cat-tail* (Typha) *marshes with other blackbirds, but prefer deciduous trees or pines* (Pinus) *in wintering locations in the southern USA.*

[*Quiscalus quiscula*, Brinkley, Arkansas, USA. Photo: Marie Read]

*For the polygynous male **Yellow-rumped Cacique**, access to females is determined by dominance, which is positively correlated with weight. Comparably sized males and those of similar rank fight more often than males that differ widely in size or rank. Female Yellow-rumped Caciques compete for access to nest-sites that are safe from predators. Weight is again the major factor determining female fledging success, since heavier females tend to win aggressive encounters and control the best nest-sites. Adolescent male Yellow-rumped Caciques avoid aggressive interactions with other males, but are very aggressive towards adult females and fledglings.*

Rio Roosevelt Lodge,
Novo Aripuanã,
Amazonas, Brazil.
Photo: Edson Endrigo]

Brazil. The Solitary and Golden-winged Caciques may occur in gallery forest and isolated forest patches in open country.

Many orioles are found in dry or xeric forests. Scott's Oriole (*Icterus parisorum*) inhabits the fringes of deserts in the south-western USA and northern Mexico. It does, however, require the presence of trees or other tall plants, such as desert yuccas (*Yucca*), for nesting. The Venezuelan Troupial (*Icterus icterus*) lives in xeric woodlands and scrub on the Caribbean coast of Venezuela and nearby islands. Similarly, the Campo Troupial lives in the semi-desertic scrub and deciduous forest of north-eastern Brazil, a habitat known as *caatinga*. The very rare Forbes's Blackbird lives in relict mesic forests within the *caatinga*.

Thorn-woodlands and thornbush savannas in central Argentina are inhabited by Greyish Baywings and Screaming Cowbirds (*Molothrus rufoaxillaris*). In the Andes of north-western Argentina, the former species lives near the desert in the dry intermontane valleys, even foraging in creosote bushes (*Larrea*), but it needs trees for nesting and roosting. No icterids are found in extreme deserts, such as the Atacama, in north Chile, or in the high-altitude *punas* of the central Andes. Although Scrub Blackbirds (*Dives warczewiczi*) live along the almost rainless coast of Peru, they are found there mostly at oases or riparian areas, or around irrigated farmland. The Bolivian Blackbird (*Oreopsar bolivianus*), is confined to that country, where it lives in dry Andean valleys below the *puna*; despite its generic name, which can be loosely translated as "mountain blackbird", its main adaptation to mountain conditions is that it nests in rocky cliffs. The southern temperate *Nothofagus* forests are inhabited by the Austral Blackbird (*Curaeus curaeus*), the southernmost representative of the family. This icterid, however, is seldom found far from clearings and the forest edge, and it occurs also in the Mediterranean-type scrub and woodland of central Chile.

*Males of polygynous icterids such as the **Red-rumped Cacique**, which play little or no part in nesting or care of the young, occupy themselves instead with displaying, resting and long bouts of feather maintenance. A male Amazonian Oropendola* (Psarocolius yuracares) *can spend up to 18% of his time at the colony in preening.*

Wetlands are extremely important for many icterids, particularly those in the grackle group. Throughout the Americas, species in the genera *Agelaius* and *Chrysomus* are the typical marsh-dwelling blackbirds, both nesting and roosting in or near marsh vegetation. One species, the Yellow-winged Blackbird (*Agelasticus thilius*), has a highland subspecies, *alticola*, that regularly nests around the shores of Lake Titicaca, straddling the Peru–Bolivia border, at 3810 m above sea-level. It is found also, probably rarely, at up to 4000 m; no other icterid has been recorded at higher elevations. Other marsh blackbirds include the showy Yellow-headed and Scarlet-headed Blackbirds of, respectively, North America and South America.

Good examples of the colonizing capabilities of icterids are the "highland enclaves" of species otherwise confined to marshes and grasslands in the lowlands. The subspecies *alticola* of the Yellow-winged Blackbird has already been mentioned. In addition, the Yellow-hooded Blackbird has one highland enclave at 2600 m on the Cundinamarca Plateau of Colombia, and even the

Allopreening, or mutual preening, has been observed for a number of icterid species, including the ***Greyish Baywing****. In captivity, a baywing was observed to solicit preening by sidling towards another bird while holding its bill pointing downwards and its feathers sleeked. If the other responded, it raised its bill and fluffed the feathers of its head and neck. Icterids may also solicit preening from other species. Cowbirds* (Molothrus) *display the "allopreening-invitation posture", head down and feathers fluffed, towards potential hosts. This may be appeasement, or the cowbird recalling being preened by its foster-parent as a nestling.*

[*Agelaioides badius badius*, Costanera Sur Ecological Reserve, Buenos Aires, Argentina. Photo: Roberto Mario Güller]

rare Saffron-cowled Blackbird demonstrates this colonizing trait, with populations in grasslands at 900–1000 m at the top of the mountains of Rio Grande do Sul, in south-east Brazil.

Throughout their ranges, the parasitic cowbirds frequent open areas and avoid dense forests. Because they do not build a nest and rear their own young, they may have disjunct feeding and breeding areas during the reproductive season. In the Sierra Nevada, in California, radio-tracking studies revealed that Brown-headed Cowbirds (*Molothrus ater*) commuted seven kilometres every day from feeding grounds to sites with abundant host nests. Giant Cowbirds are found in savannas and the edges of tropical forests, and forage also in open habitats along main rivers, while Screaming Cowbirds frequent light woodland mixed with grassland. Shiny Cowbirds occur in most open habitats, and commonly visit marshes during the breeding season.

Grasslands of several types, including both tall and short grass, are the typical biome of meadowlarks. Lilian's Meadowlark is adapted to desert grasslands, being found only in the south USA and adjacent north Mexico. The Long-tailed Meadowlark, on the other hand, is restricted to the southern Neotropics, one of its four subspecies, *catamarcana*, reaching 3200 m in the southern Andes, where it inhabits wet or marshy grassland just below the level of the bleak *puna* highlands. The Red-breasted and White-browed Blackbirds, both formerly placed in the genus *Leistes* but now classified as *Sturnella* meadowlarks (see Systematics), prefer wet grassland in the lowlands. One member of this genus, the Pampas Meadowlark, is entirely adapted for a life in the pure grassland of treeless country.

Wet grassland is the typical habitat of the Brown-and-yellow Marshbird (*Pseudoleistes virescens*) and the Saffron-cowled Blackbird, both of which can live also in treeless areas, roosting and nesting in or near marshes. Finally, the Bobolink, a long-distance migrant, breeds in damp meadows in North America, after which it flies southwards to central South America, where it utilizes the same kind of habitat, including rice fields.

As a family, icterids have been remarkably successful in invading man-made environments. Examples of highly adaptable species can be found in all icterid groups. Tropical plantations of bananas, cacao and other foods are regularly visited by Crested and Montezuma Oropendolas. Oriole species, such as the Orchard and Baltimore Orioles, inhabit city parks and orchards, and members of this family found in suburban environments with large gardens, lawns and golf courses include Common and Great-tailed Grackles, Brewer's Blackbirds, Cuban Blackbirds and baywings. Many marsh blackbirds in the genera *Agelaius* and *Chrysomus* can be found in rice fields, which are exploited also by Bobolinks and by Red-breasted and White-browed Blackbirds. Farmland and pastures are attractive to all parasitic cowbirds, as well as to meadowlarks. Even some rare or globally threatened icterids may be found in, or will use, somewhat modified environments. Saffron-cowled Blackbirds can survive in agricultural land, and the rare Forbes's Blackbird nests in introduced mango (*Mangifera*) trees. As an exception, the declining Pampas Meadowlark has not been able to survive in the crop fields that have replaced most of its native grasslands, and it is now listed as Vulnerable (see Status and Conservation).

General Habits

With a few exceptions, icterids are relatively easy to observe and to study. As already mentioned (see Habitat), many species frequent open areas such as grassland, marshes, dry scrub and savannas, where they are rendered conspicuous by their coloration and voice. Some are strikingly conspicuous in plumage, a good example being the Orange-backed Troupial in the dusty, brownish winter scrub of the dry Chaco, or the Scarlet-headed Blackbird with a background of lush green marsh vegetation. Those icterids having drab brownish or olivaceous plumage are often females of sexually dichromatic species (see Morphological Aspects). The baywings in the genus *Agelaioides* have subdued brownish and greyish plumage in both sexes, but are conspicuous because of their voice and behaviour.

Species living in forest or woodland biomes often become more conspicuous through their habit of utilizing the edges and canopy. Only the Yellow-billed Cacique skulks in dense undergrowth and bamboo patches, where it is seldom observed but is, nevertheless, detectable because of its characteristic songs and calls. The Solitary Cacique also frequents thick undergrowth, but it commonly builds its large nest in more exposed locations.

Most of the terrestrial icterids walk or run on the ground, but the more arboreal species move by hopping or jumping. The plum-

The plumage-maintenance behaviour of icterids commonly involves much water-bathing, but dust-bathing and anting are less often reported. The ***Common Grackle****, however, has been observed anting and indulging in anting-like behaviour with other objects, such as marigold flowers* (Calendula officinalis). *These flowers have antibacterial properties and also contain insecticidal pyrethrum and also sitosterol, a chemical known to inhibit egg-laying in mites. A male Common Grackle was seen anting with half a lime, preening itself while holding bits of the fruit in its bill.*

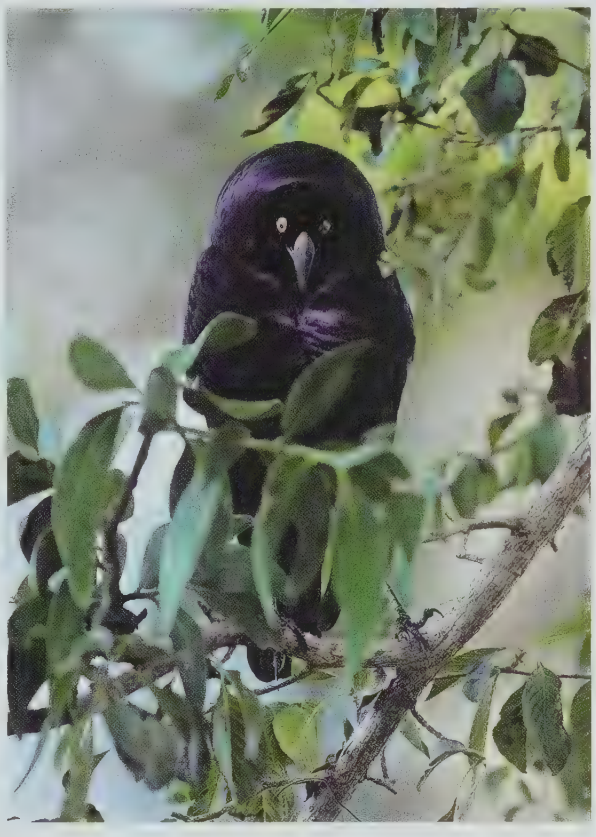
[*Quiscalus quiscula*, SW Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

age-maintenance behaviour commonly involves much water-bathing, but dust-bathing and anting are less commonly reported. Preening is frequent, and allopreening, involving the mutual care of body plumage by two or more individuals, is performed by a few species.

Many field guides characterize icterids as sociable or gregarious birds, and this is, indeed, true of most species in the family. Icterids breed in colonies far more frequently than any of the related families of tanagers, New World warblers or New World sparrows. Even species that breed as solitary pairs or family groups may form flocks in the non-breeding season. Post-breeding flocks are sometimes segregated according to sex and age, the females and juveniles moving separately from the males. Icterid flocks can be huge. In North America, those of such species as the Red-winged Blackbird can contain hundreds of thousands of individuals. In the Neotropics, flocks contain hundreds or thousands of individuals, only rarely more. Mixed flocks consisting of individuals of two or more icterid species also occur.

The "Bill-tilt" or "Head Up" display, used in aggressive interactions, has been recorded for a wide range of icterid genera. Both sexes of the ***Great-tailed Grackle*** *use the display, though usually only in the presence of their own sex. It is much more commonly performed by males. In silence, the birds sleek their feathers and raise the bill to the vertical or beyond. Bill-tilting may be used also in flight. As it approaches its opponent, the bird momentarily closes its wings, and extends its head and neck upwards until its body is nearly vertical.*

[*Quiscalus mexicanus prosopidicola*, near McAllen, Texas, USA. Photo: Stephen J. Krasemann/DRK]



New World blackbirds also join birds from other families to form mixed flocks. In the Neotropics, caciques and oropendolas often consort with jays (Corvidae). Other passerines that flock with icterids include tanagers and some cotingas (Cotingidae). Some Andean icterids that commonly move in mixed flocks include the two mountain caciques, the Scarlet-rumped Cacique and the Red-bellied Grackle. Neotropical icterids seldom associate with antbirds (Thamnophilidae) and woodcreepers (Dendrocolaptidae) that follow army ants (Formicidae), but Yellow-billed Caciques have been reported as doing so.

A general and characteristic habit of the family is that of roosting communally in dense vegetation. The few exceptions involve species that live as permanent territorial pairs. Some species roost gregariously in marsh vegetation, while others roost in native or exotic bamboo or, in Amazonia, in patches of *Gynerium* canes. Not all icterids, however, select these types of roosting location. For example, wintering Shiny Cowbirds in Argentina commonly roost in trees in towns and cities, but they will choose even leafless trees under streetlights, places that attract no other icterids. Greyish Baywings in Argentina rarely, if ever, roost in marsh vegetation, and they also avoid leafless trees. A medium-sized orange tree in a patch of deciduous woodland may attract wintering individuals from a large area. On the other hand, popular roosting sites in stands of evergreen plants such as bamboo may be shared by several species. Roost-sites are usually traditional, and are used year after year.

During the winter months, icterid roosts in North America can contain amazing numbers of individuals. Surveys carried by the US Fish & Wildlife Service in the mid-1970s revealed that 438,000,000 icterids were roosting at 723 main sites, giving an average of more than 600,000 icterids per main roost-site. The more numerous species attending these roosts were the Red-winged Blackbird, Common Grackle and Brown-headed Cowbird. Huge concentrations of this nature are often regarded as an environmental problem to humans and their agricultural crops (see Relationship with Man). In the Neotropics the roosts are smaller, probably because Neotropical icterids are sedentary or do not migrate in big flocks. The largest roosts observed nowadays in Argentina during the austral winter contain about 2000 individuals of up to three species.

Birds that forage in flocks of any kind may benefit from enhanced detection of predators, whether aerial or terrestrial. A potential disadvantage is that, if resources are limited, feeding competition among flock-members may arise. Species in mixed flocks may eat different foods and have different foraging techniques, thereby minimizing this problem.

Groups or flocks of New World blackbirds foraging on the ground often exhibit "roller-feeding" behaviour. The individuals foraging at the rear end of the group fly over their flockmates to the front, and stay in position until, as the process is constantly repeated by the rearmost flock-members, they finally find them-

*The displaying male **Giant Cowbird** fluffs out his body feathers and erects the ruff of feathers around his neck, giving him an owl-like appearance. He arches his neck and leans his head forwards and down, until his bill rests on his fluffed-out breast feathers. He may also bob up and down by flexing his legs. Icterids that communicate mostly by postures and plumage features have fewer vocal signals. The Giant Cowbird is generally rather silent. Great-tailed* (Quiscalus mexicanus) *and Boat-tailed Grackles* (Q. major) *beat their wings during displays, but the odd noises heard at this time are apparently not made by the wings.*

[*Molothrus oryzivorus oryzivorus*, Aguapé Lodge, Aquidauana, Mato Grosso do Sul, Brazil. Photo: Edson Endrigo]

*Male icterids in several genera have a perched display, the "Song Spread", in which the head is lowered, the body feathers raised, and the wings and tail spread while the bird sings. This display shows off the epaulets of the male **Red-winged Blackbird** to advantage, although they are probably directed at other males rather than at females. The size of the epaulets is a reliable predictor of dominance rank. When some males in a population had their epaulets artificially blackened, 64% lost their territories, while only 8% of males with normal epaulets lost theirs. Nevertheless, males with epaulets blackened were still able to attract and mate with females.*

[*Agelaius phoeniceus phoeniceus*, Québec, Canada. Photo: Daniel Houx]

The male ***Orchard Oriole*** *sings in flight, as well as from perches. The female of this species may also sing. Icterid species in which the sexes have similar songs occur mainly in the tropics and include most of the* Icterus *orioles. The female Streak-backed Oriole* (Icterus pustulatus) *not only produces songs of similar complexity to the male's, but sings more frequently. Some closely related* Icterus *species have very dissimilar songs, but more distantly related orioles can sound very similar. Orchard, Bullock's* (I. bullockii) *and Hooded Orioles* (I. cucullatus) *have largely non-overlapping ranges and differ from one another in plumage colours and patterns, yet have strikingly similar songs, quite different from the lazy whistles typical of many other oriole species.*

[*Icterus spurius*, Carver County, Minnesota, USA. Photo: Stan Tekiela/DRK]

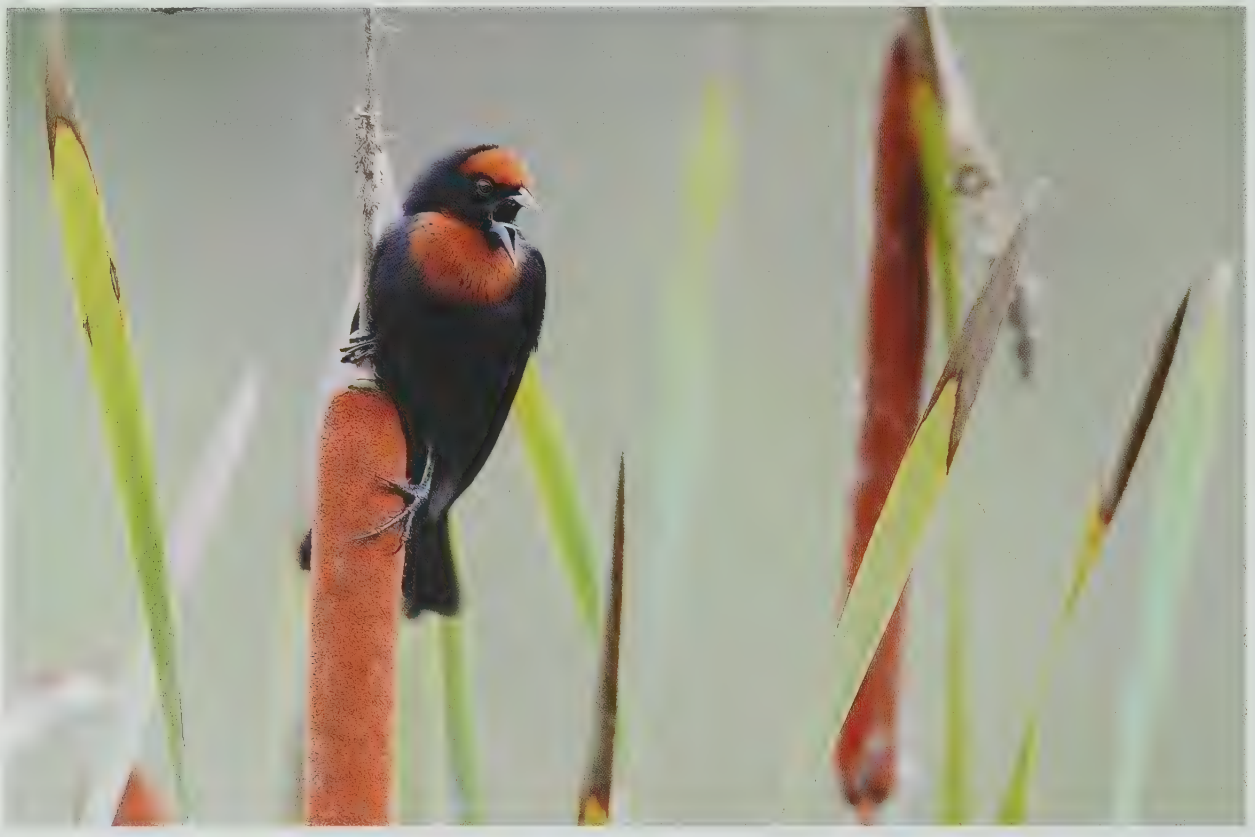
selves again at the back; after a short time they fly to the front again, and the entire procedure is repeated. The resulting pattern suggests that the flock is slowly "rolling" over the fields. Some icterids exhibit more sophisticated group behaviour. As an example, several South American species that breed co-operatively, particularly those that forage on the ground, such as marshbirds, baywings and Chopi Blackbirds, have developed elaborate sentinel behaviour. Typically, one or two group-members take up position on elevated perches and spend their time in watching for possible predators, including visiting ornithologists. While keeping a lookout, the sentinels may produce a series of calls, perhaps meaning that no threats are imminent. If a potential predator is detected, or if the ornithologist comes too close, the sentinels produce different types of call as an alarm.

Icterid displays that have been studied relate mostly to North American species, but a few displays and postures are more or less widespread throughout the family. A frequent aggressive or threat posture, in which the head and bill are raised vertically, is called the "Bill Up" or "Head Up". Sometimes the bird gives this threat while slowly flying towards a rival. The Bill Up is often performed by the *Quiscalus* grackles. An unusual variation of this threat display is given by the Greyish Baywing, which holds a twig or a leaf at the tip of its raised bill.

Voice

Few bird families in the Americas rival the icterids in the complexity and diversity of their vocalizations. Within the New World nine-primaried oscines, only the New World sparrows come close. Ornithologists have attempted to quantify the vocal repertoire of icterid species, the total number of different sounds produced by each one, but there is considerable subjectivity on how to assess every variant. Students of avian behaviour define song as the more elaborate vocalizations used for sexual attraction and/or aggressive contests, for instance in territorial defence. The rest of the repertoire consists of several calls, classified as alarm calls, contact calls, begging calls, and so on, depending on the context and the behaviour that they can elicit. In some cases, however, the distinction between songs and calls may be considered rather arbitrary.

In the USA, it is claimed that Red-winged Blackbirds have 20 different vocalizations, Brewer's Blackbird 13 and Eastern Meadowlarks 12. For the same species, Orians gives figures of, respectively, 18, 9 and 9. According to Schäfer, the Russet-backed Oropendola in Venezuela produces 16 different vocalizations. Greyish Baywings in Argentina have a minimum of nine recognizable vocalizations, eight basic calls and the song; the calls are the contact call, contact whistle, terrestrial alarm, aerial alarm, mobbing call, distress call, feeding call, and begging call, and the song has three possible variants, including group song. As with other bird species, some calls are rather stereotyped and invariable, the aerial alarm call being an example, whereas other calls change gradually according to motivation, as is the case with the terrestrial alarm call. Further, the begging calls of chicks change considerably with age, and more than one type may be recognized.



Despite the difficulties of quantifying repertoires, there are real differences not only among species but also, in some cases, between the sexes. According to Orians, male Red-winged Blackbirds have 18 different vocalizations, whereas females have only six. The corresponding values for the closely related Tricolored Blackbird (*Agelaius tricolor*) are 17 and six, males apparently lacking only aerial alarm calls. The tendency for males to have a richer repertoire suggests the operation of sexual selection, favouring more types of sound in polygynous male icterids. Monogamous icterids, on the other hand, have fewer vocalizations and the two sexes are similar in repertoire size. A striking example is provided by the monogamous Red-shouldered Blackbird (*Agelaius assimilis*) of Cuba, which lacks the "sexual inequality" in vocal repertoire that is a feature of its close relative the polygynous Red-winged Blackbird.

Another recognizable trend is that icterids that communicate mostly by means of postures and the use of plumage features have fewer vocal signals. In other words, visual displays replace acoustic displays. This is the alleged case with Yellow-headed Blackbirds, whose males are polygynous but produce only eight types of vocalization. According to Schäfer, the ex-

Some caciques and oropendolas are renowned for their loud, bizarre and virtuosic vocalizations, with many odd harmonics and sudden modulations. It has been suggested that the sound "kshárá-chee", which forms part of the song of the ***Yellow-winged Cacique****, can, with a little imagination, be transformed into the name "cacique". The song has been described as beginning with various liquid notes, followed by a sound like that made by a rusty-hinged barn door when swinging open. Among many differences between the Yellow-winged Cacique and the "true" caciques are the former's possession of a crest, its nesting habits and its habitat, in all of which it is closer to the oropendolas* (Psarocolius). *Oropendola songs are audible at hundreds of metres. A study found that the length of notes within the songs of oropendolas was correlated with the degree of size dimorphism between the sexes. Males of more dimorphic species are generally larger than the males of less dimorphic oropendolas, presumably have greater lung capacities than do smaller males, and thus are able to expel more air and produce longer continuous sounds.*

[*Cassiculus melanicterus*, Puerto Angel, Oaxaca, Mexico. Photo: Edward Vercruysse]

*The male **Chestnut-capped Blackbird** has two song types, sometimes produced in alternate sequences. One, often delivered with the wings and tail spread, starts with clicks, warbles or whistles and ends in a descending nasal buzz. The other is more individual and less stereotyped, and can be quite musical and flute-like. There is much variation among the songs of the males of this species, even within a single colony. The songs of the two races of Chestnut-capped Blackbird are similar, although that of the northern race,* frontalis, *is harsher in tone.*

[*Chrysomus ruficapillus frontalis*, Pedra Azul, Espírito Santo, Brazil. Photo: Edson Endrigo]

tent of the vocal repertoire of the "yellow-billed group" of the Russet-backed Oropendola (see Systematics) is correlated with a low frequency of visual contacts in the dense subtropical forest in which the species lives. The prediction of both trends would be that polygynous icterids living in dense forest, which include many caciques and oropendolas, will have the largest sound repertoires.

Most elaborate singing is usually produced by males, and this is quite obvious in polygynous colonial species such as the oropendolas or the large grackles. Females' songs can be divided into two kinds: those that are basically similar to the male's songs, and those that are divergent, often simpler, but functionally equivalent to the male song. Among Nearctic species, distinctive female songs are a characteristic of the Red-winged, Yellow-headed and Rusty Blackbirds. A well-known example of divergent female song is the chatter or rattle heard from many female blackbirds, including cowbirds. The Shiny Cowbird female uses the chatter mostly during the breeding season, when it presumably helps to attract males. It is used also during aggressive interactions between females, or even when females attack males. Oddly, males of this cowbird species sometimes incorporate chatters within their elaborate flight song. If this broader definition of female song is used, it can be said that females of many, perhaps the majority of, icterid taxa sing.

Icterid species in which the sexes have similar songs occur mostly in the Neotropics. The similarity is found, for instance, in most *Icterus* orioles, in the solitary-nesting caciques, among the grackle clade, including the Greyish Baywing and the Scrub, Chopi and Saffron-cowled Blackbirds, and among meadowlarks, principally the Long-tailed Meadowlark. Moreover, some oriole females may sing more elaborate songs, or have a higher song production, than males of the species. A recent phylogenetic analysis strongly suggests that, among icterid genera that have moved from the Neotropics to the Nearctic Region, females have lost the male-type songs and have evolved simpler but equivalent vocalizations.

The vocal diversity of icterids is as rich as are most behavioural traits found in the family, and even congeneric species may display considerable divergence in songs. One of the simplest of icterid songs is produced by male Screaming Cowbirds, the song of which is an explosive and harsh whistled or warbled sound, lasting for less than a half-second, and audible at hundreds of metres. Males sing from an exposed perch during a "Song Spread" display, known also as the "Ruff-out" display, in which the wings and tail are held open (see Breeding). Female Screaming Cowbirds duet with the mate by producing a harsh rattle, the notes so compressed in time as to be perceived as a single blast of noise. The song of the related Giant Cowbird is likewise simple, consisting of a brief series of whistles, or a single modulated whistle, with a rasping quality. The male Shiny Cowbird, on the other hand, has two types of song. One, given only by perched individuals, is a series of low-pitched gurgles followed by two or three high-pitched whistles. The second song, sometimes delivered in flight, is a descending whistle followed by a string of variable, fast twittering and rattling notes. Flight songs, commonly known also as twittering songs, can last for three or more seconds. The male Brown-headed Cowbird has a similar perched song, but its flight song is reduced to a whistle. Females of the Shiny and Brown-headed Cowbirds closely resemble each other in producing slower rattling or chattering calls, which are functionally equivalent to the male's songs. It would appear that, within the parasitic cowbirds, song resemblance mirrors the molecular phylogeny (see Systematics).

The song diversity of the Icteridae may be a result of variation not only in the type and number of syllables, whether discrete notes or note groups, and of phrases, in the form of groups of syllables, but also in the harmonic structure of each note. An interesting example of variation in harmonic structure is provided by three South American blackbirds belonging to the same clade. The Greyish Baywing has a complex and variable structure of phrases, but many of its notes emphasize just one harmonic. The richer song of the Chopi Blackbird is similar, but with a strong emphasis on consonant harmonics. Lastly, all notes of the song of the Austral Blackbird have a strong harmonic structure, with a peculiar nasal, oboe-like timbre.

Some members of this family produce a "continuous" song, a seemingly endless succession of variable sounds, such as whistles, buzzes, twitters and the like, lacking a definite pattern of repetition. Baywings and Austral and Chopi Blackbirds commonly produce such songs. During the breeding period, however, male baywings also sing shorter and more stereotyped songs, repeated every time they visit the nest. In one study, it was possible to

*The harsh and explosive song of the male **Screaming Cowbird** lasts for barely half a second and can be heard for hundreds of metres. It is often preceded by a low growl, audible only at close range. The female may answer with a loud rasping rattle, in a kind of duet. As in the male's song, the notes of the female's are so compressed that they are apprehended by human ears as a single blast of noise. Unlike other cowbirds, Screaming Cowbirds are apparently exclusively monogamous and the male accompanies the female constantly. As females inspect host nests, males typically perch above them, vocalizing and performing the "Song Spread" display.*

[*Molothrus rufoaxillaris*, Aguapé Lodge, Aquidauana, Mato Grosso do Sul, Brazil. Photo: Edson Endrigo]

recognize some ringed male baywings at a distance by these repetitive songs. Song duets between the male and the female, each sex with a different vocalization, are known to be performed by such diverse icterids as the Yellow-billed Cacique, the Golden-winged Cacique, the Yellow-tailed Oriole (*Icterus mesomelas*), the Melodious Blackbird and the Screaming Cowbird.

Several icterid species have more than one basic type of song. Nearctic species with two song types include the Yellow-headed, Brewer's and Rusty Blackbirds. The Eastern, Western and Pampas Meadowlarks deliver one kind of song from a perch and a different song in flight, as also does the White-browed Blackbird. Males of this last species also produce a softer and more complex song, often while pursuing females. Male Chestnut-capped Blackbirds (*Chrysomus ruficapillus*) have two song types, sometimes rendered in alternate sequences. One song starts with clicks or whistles and ends with a nasal buzz; breeding males assume a puffed-out posture during this song, spreading the wings and tail in display (see Breeding). The other song is less stereotyped and often quite musical, being either a series of loud, short and tremulous whistles around a sustained pitch, like a flute playing coloratura, or a sequence of flute-like notes ascending the scale. Breeding males raise and flutter their wings while singing, usually addressing a nearby female. Three general song types are used by male Yellow-rumped Caciques in Panama, each one associated with a different aspect of behaviour; one, low-pitched and more musical, is used in flight.

Group singing is an activity of most icterids that flock, and is commonly heard at roosting sites. Among species of southern South America, it has been further developed by both marshbirds, the Chopi Blackbird and the Greyish Baywing. In the case of the highly social Yellow-rumped Marshbird (*Pseudoleistes guirahuro*) and the Brown-and-yellow Marshbird it is far more frequent than solo singing. Group singing by Greyish Baywings involves continuous singing by individuals of both sexes, in a kind of random polyphony. The regularity of the performance by this species is responsible for its common Argentinian name of *músico*, meaning "musician", because of its alleged resemblance to the sound made by an orchestra when tuning up, each instrument practising a different theme. Group singing by baywings may occur during agonistic encounters between groups, at any time and away from roosts.

Mimicry, the vocal copying of sounds produced by other species, has been reported for some species of *Cacicus* and some *Icterus*, but it may also be a feature of other species, such as the Chopi Blackbird. The ornithologist Sick mentioned an imitation of the cry of a giant otter (*Pteronura brasiliensis*) by a Yellow-rumped Cacique that was so well rendered as to confuse a party of hunters. With this cacique, mimicry is performed mostly, or only, by the southern, nominate race, which also faithfully copies

*Several icterid species have more than one basic type of song. The **Eastern Meadowlark** delivers one song from a perch and a different song in flight. The female produces a chatter, which is possibly equivalent to male song. Both this species and the Western Meadowlark (Sturnella neglecta) produce pleasant whistling notes, but the song of the Western species is more complex and musical, and song is one of the main criteria for separating these very similar species in the field. Geographically distant populations of Eastern Meadowlarks, however, have divergent song types, and those in northern South America, where Western Meadowlarks are absent, are said to have a song variant that is less easy to distinguish.*

[*Sturnella magna argutula*, Brazoria County, Texas, USA. Photo: Brian E. Small]

such birds as parrots (Psittacidae) and woodpeckers (Picidae). There is no satisfactory explanation for the discrepancy in the performing of mimicry among icterids so closely related as to be classified as races of a single species.

Another remarkable mimic is the Variable Oriole, which copies the calls of hawks, mostly those of the Roadside Hawk (*Buteo magnirostris*), and the contact and alarm calls of such birds as the Guira Cuckoo (*Guira guira*), the Rufous Hornero (*Furnarius rufus*) and the Great Kiskadee (*Pitangus sulphuratus*). The imitations are remarkably accurate, but are uttered in a softer voice than that of the model. This oriole also mimics the scolding calls of Chalk-browed Mockingbirds (*Mimus saturninus*), and at times it may be answered by the mockingbirds. Mimicry is a feature of other orioles, too. Many icterids give buzzy, nasal or rasping songs containing frequency-modulated tones or notes. Instead of producing sounds at a constant pitch, they introduce a pattern of fast modulations above and below a basic tone. Above a fixed level of modulation human ears perceive such sounds as being unmusical and rough, and this is the case with most icterid sounds of this type. Frequency-modulated songs are common among marsh and grassland species in the grackle and meadowlark groups. Songs of many *Agelaius* and *Chrysomus* blackbirds end in prolonged nasal or buzzy sounds, and most grackles produce rasping, rattling or dissonant sounds. The Greater Antillean Grackle (*Quiscalus niger*) and the Carib Grackle, however, produce more musical songs, and the Melodious and Chopi Blackbirds, two species with rich, pleasant musical songs, belong to this group. Meadowlarks are a variable group in terms of the tonal quality of their songs, with some accomplished songsters, such as the Western and Eastern Meadowlarks. Although in the meadowlark group, the Yellow-headed Blackbird produces particularly unmusical songs, one of which has been likened to the noise of an unwinding clockwork machine.

Some caciques and oropendolas are renowned for their loud, virtuoso and bizarre vocalizations, with many odd harmonics and sudden modulations, quite difficult to describe verbally or musically. A detailed analysis of cacique and oropendola songs by J. Price and Lanyon involved the use of 29 variables to describe the songs. Songs of several species have been described as being liquid gurgles, and others as hollow whistles. The Amazonian Oropendola incorporates sounds suggesting arpeggios played on some plucked instrument, but one with wooden strings, simultaneously with others that resemble chords played on large bamboo pipes. Songs of male Montezuma Oropendolas in Costa Rica may include remarkable crescendos, growing simultaneously in intensity and range of pitch, and ending in a shrill whistle. Oropendola songs are audible at hundreds of metres. From a distance they may sound more pleasant, because much of the harshness and noise that surrounds the fundamental tones is then lost.

Orioles as a group deliver rather musical songs. The Yellow-backed Oriole (*Icterus chrysater*), a songster of repute, produces whistled songs within a rather narrow pitch range. Sometimes its notes are arranged in paired sequences, ascending and descending, suggesting a pattern of questions and answers. Other orioles include in their songs non-whistled notes, such as trills, warbles and even harsh sounds. Some *Icterus* species outstanding for their songs include the Spot-breasted Oriole (*Icterus pectoralis*) and the Campo Troupial, in addition to the Yellow-backed Oriole.

Orians advanced the theory that icterids having small, clumped territories communicate mostly with frequency-modulated tones, because such sounds may be more easily heard and located by conspecifics living at short distances. Icterids that live in large, dispersed territories would, rather, use pure, more musical notes with a lower degradation rate; such sounds would carry the message even to distant neighbours. In order to assess the validity of this hypothesis, it is necessary to test the correlation between territory size and tonal quality of songs with a group of closely related species, such as the orioles or the caciques. The songs of oropendolas degrade with distance, this being compatible with Orian's views on short-distance and long-distance communication. The evidence for some species that live in groups, such as the two baywings and the Chopi Blackbird, will be ambiguous. All three species produce more musical sounds than those of most members of the grackle group, but the Austral Blackbird, also a group-living icterid and in the same South American clade, communicates with mostly nasal, less musical sounds.

In the context of the oscine passerines, icterids learn a good deal of their sound repertoire, particularly the songs. In the case of one of the best-known species, the Red-winged Blackbird, males can continue to learn songs, and probably from many conspecific adults, until their second year. Song-learning by the

Throughout the year, the ***Rusty Blackbird*** *takes advantage of whatever food is abundant. Insects, mainly beetles (Coleoptera) and grasshoppers (Orthoptera), and the adults of aquatic insects emerging after metamorphosis, are a primary food in summer, and nestlings are fed with adult dragonflies (Odonata). Rusty Blackbirds will also take molluscs, frogs and salamanders. Outside the breeding season, seeds, including grass seeds and cereals, and tree seeds such as acorns and pine nuts* (Pinus), *become important. In harsh weather Rusty Blackbirds may also kill and eat small birds, including sparrows and finches.*

[*Euphagus carolinus*, Chicago, Illinois. Photo: Rob Curtis/ The Early Birder]

parasitic cowbirds has attracted some attention, because juvenile cowbirds do not learn songs from their host species. With sedentary cowbirds, such as the Screaming Cowbird, the young start to flock with conspecific adults in their second month of life, and probably begin to learn from them. Song-practising juvenile Screaming Cowbirds sometimes form small groups, and possibly learn from one another. Experiments have shown that male Brown-headed Cowbirds reared in total isolation develop normal songs, an unusual fact for oscine passerines. Nevertheless, the isolated males could later modify their song through learning and interactions with conspecifics of both sexes. Males may learn song elements from conspecifics in their first year, but they do not develop full singing until the following year.

As would be expected, the songs of any icterid species can show variation at several levels. Thus, a single individual can have several different songs, the individual repertoire; in addition, songs can vary among individuals, and between populations at a microgeographical scale, involving dialects, and they can vary on a large geographical scale. The individual repertoires of male Red-winged Blackbirds, for example, include about five song variants. F. Feekes noticed that individual male Yellow-rumped Caciques in Suriname produce two song types, but these changed gradually with time, so that lifetime repertoires were vast. This cacique is an outstanding mimic, and probably continues learning as an adult. Considerable song variation among individuals is evident too in the dwindling populations of the rare Saffron-cowled Blackbird.

Microgeographical variation in characteristics of the song is a feature of many icterids. The existence of different local variants, or dialects, should be kept in mind when interpreting statements made in field guides and other literature on this family. As with human languages, dialects develop mostly among icterids having relatively isolated and sedentary populations. With Red-winged Blackbirds in North America, for instance, the northern populations, which are mostly migratory, exhibit little geographical variation in song, but dialectal variants are frequent in the resident populations of this species in Florida and California. Feekes described an unusual type of dialect system for Yellow-rumped Caciques. This icterid nests in colonies and, although individual differences in song occur, the songs of males frequenting the same colony are similar to one another, and different from those of males in other colonies. These colony-shared song types could work as "passwords", used by local males to detect outsiders.

A well-known example of geographical variation in icterid songs concerns the insular Greater Antillean and Carib Grackles. The systematist R. K. Selander found that each island has its own different song type, at times quite distinctive. In the case of the Carib Grackle, songs from Trinidad, for instance, have little in common with songs from Martinique. The Eastern and Long-tailed Meadowlarks, two species with extensive distributions, likewise have divergent song types in some populations.

Some characteristics of songs and calls may be inherited. One of the simplest rules of song variation is related to size: a decrease in body size is correlated with an increase in pitch, as is the case also with musical instruments. The widespread Shiny Cowbird has a rather small subspecies, *minimus*, in the Caribbean, and the flight song of this race has a noticeably higher pitch than that of songs of the nominate race. In other cases, geographical variation in pitch and tonal quality of sounds may be related to the acoustical properties of different environments, with natural selection for more efficient sound transmission. Forest environments would select for smaller pitch ranges and more pure-toned, musical songs. Besides natural selection, sexual selection, or mate choice, is a probable influence on the evolution of icterid signals.

Mechanical sounds made by icterids consist mostly of noises produced by flapping of the wings. Many large orioles and grackles, as well as Giant and Screaming Cowbirds, can produce an audible wing sound when flying. Great-tailed and Boat-tailed Grackles beat their wings during displays, but the odd noises heard at this time apparently are not made by the wings. Mechanical sounds are quite well developed in oropendolas and caciques. The male Crested Oropendola ends its song with a rhythmic series of up to 30 wing-flaps, lasting two to three seconds. Males of some populations of Red-rumped Caciques produce hissing sounds, somewhat reminiscent of noises made by bellows, while flapping the wings, even during short flights. The role of the wings in the production of this noise has not been researched.

From the viewpoint of systematics, icterid voices, particularly the songs, have been suggested as tools for assessing whether

Most members of the family will use the feet to pin down prey while they deal with it. The ***Chopi Blackbird*** *eats millipedes (Diplopoda) and other arthropods, and also small vertebrates. One was watched as it fed on a still-warm immature Yellow-billed Cardinal* (Paroaria capitata) *in the Brazilian Pantanal. The blackbird was not seen to kill the young bird, but predation was thought highly likely, since a local resident reported having seen 2–3 Chopi Blackbirds attacking a young cardinal two weeks earlier.*

[*Gnorimopsar chopi chopi*, Serra da Canastra National Park, São Roque de Minas, Minas Gerais, Brazil. Photo: Edson Endrigo]

Two species of cowbird, the ***Giant Cowbird*** *and the Shiny Cowbird* (Molothrus bonariensis), *are recorded as gleaning food, presumably ticks (Ixodida), from capybaras* (Hydrochoerus hydrochaeris). *Cowbirds follow these and other large mammals to exploit the insects which they disturb, often using the mammal's back as a perch. The large rodents sometimes lie on their side, apparently as an invitation to the birds to clean the parasites from their belly. The Giant Cowbird has also been recorded as picking food from the side, shoulder and neck of a resting marsh deer* (Blastocerus dichotomus).

[*Molothrus oryzivorus oryzivorus*, Pantanal, Mato Grosso, Brazil. Photo: Luiz Claudio Marigo]

to treat populations under one species or several species. Some cases of potential splitting, like that of the northern population *vitellinus* of the Yellow-rumped Cacique, are quite compelling. Given the complexity of many icterid songs, the fact that they develop through learning, and their individual and dialectal variations, the subject is somewhat controversial. Nevertheless, song is one of the main criteria for separating Eastern and Western Meadowlarks in the field.

Food and Feeding

As a family, the New World blackbirds feed on small animals, and on seeds, nectar and fruits. The relative importance of these items in the diet varies considerably among species and groups. Large icterids, mostly the grackles, prey on small vertebrates, but none of them has specialized on this type of food. Common Grackles will wade in shallow water after fish and tadpoles, and Boat-tailed and Common Grackles may also catch fish by plunging from the air. Unicolored Blackbirds catch small fish near the water surface, probably by searching under floating vegetation. Small arboreal frogs (*Hyla*) are frequent prey items of Crested and Russet-backed Oropendolas in Venezuela, and have been found in the stomach contents of Scarlet-headed and Red-breasted Blackbirds in Brazil. Cuban Blackbirds commonly prey on small *Anolis* lizards.

Small birds, including other passerines, hummingbirds (Trochilidae) and even an injured Dunlin (*Calidris alpina*), have been reported as prey of Boat-tailed Grackles in Louisiana. Common Grackles have captured passerines as large as House Sparrows (*Passer domesticus*). Similarly, Rusty, Brewer's and Chopi Blackbirds kill and eat small birds, the first species mostly during harsh winter weather. Grackles are well-known nest predators, and even a large oriole such as a troupial may eat eggs and small chicks. Common Grackles sometimes consume small mammals, mostly mice (Muridae), and North American meadowlarks have been recorded as feeding on the carcasses of road-killed vertebrates.

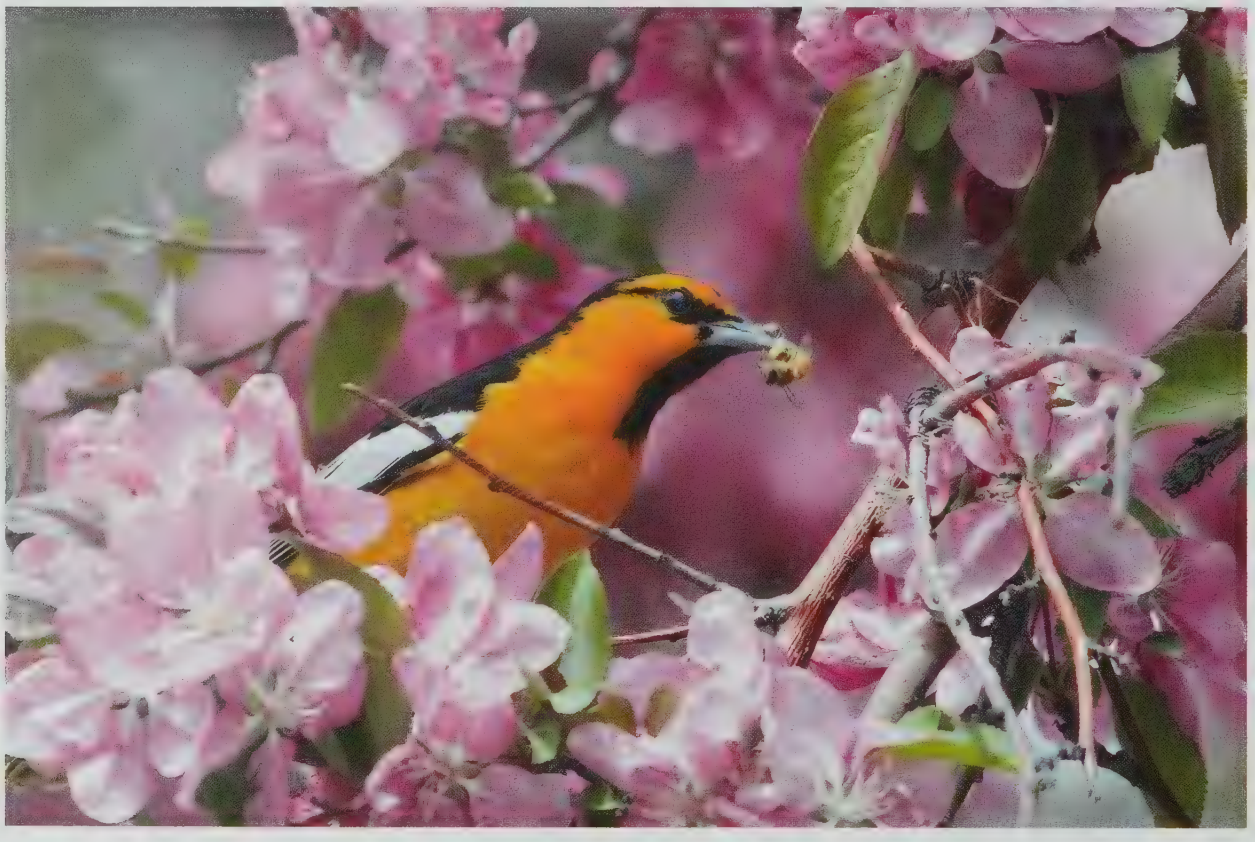
Molluscs in the form of snails and bivalves are commonly eaten by Boat-tailed Grackles, which use the method known as "gaping" (see below) to extract them from mud and sand. Crustaceans are taken by several species: crayfish (Astacoidea) are eaten by Boat-tailed and Common Grackles, and near the fjords of southern Chile Austral Blackbirds may feed mostly on shrimps (Caridea). Spiders (Araneae) are important animal prey for most icterids. Stomach contents of the Brown-and-yellow Marshbird, a highly insectivorous species of the South American *pampas*, consisted of 80% insects and 12% spiders. Marshbirds forage on the ground and consume spiders, mostly terrestrial wolf spiders (Lycosidae), particularly during the austral winter. Scorpions (Scorpiones) have been recorded in the diet of Montezuma Oropendolas in Costa Rica.

It can be safely stated that arthropods are the main animal food of the icterids, but the percentage of arthropods in the diet, and the types consumed, are too variable for meaningful generalizations to be made. Some icterids could be ranked as mostly insectivorous when arthropods exceeded 50% of the items found in stomach contents; among these are the Brown-and-yellow Marshbird (see above), the Eastern Meadowlark, the White-browed Blackbird and, in the breeding season, the Bobolink. Less insectivorous, more vegetarian species include Rusty and Brewer's Blackbirds, the Common Grackle, the Red-winged Blackbird, the Brown-headed Cowbird and baywings. In the case of the cowbird and the two baywings, the percentage of arthropods in the diet was less than 30%. It should be noted that icterid chicks, even those of the most granivorous species, are fed mostly with arthropods .

Grasshoppers (Orthoptera) are consumed mostly by grassland icterids. It is speculated that, in the past, enormous flocks of Tricolored Blackbirds tracked grasshopper outbreaks in California, and bred near the swarms. Breeding Greyish Baywings often bring large mantids (Mantidae) to chicks in the nest, while Red-winged and Yellow-headed Blackbirds in the marshes of the north-western USA capture mostly emergent larvae of dragonflies (Odonata) as nestling food. Several families of beetles (Coleoptera), particularly weevils (Curculionidae), furnish important prey for most icterids. Among butterflies and moths (Lepidoptera), the larval stages consisting of the caterpillars and pupae are probably more important prey items than adults. Nevertheless, Black-backed Orioles are well-known consumers of the toxic adults of monarch butterflies (*Danaus plexippus*) that spend the winter months in Mexico.

Before European settlement of North America, the ***Brown-headed Cowbird*** *probably relied on large grazing ungulates, in particular the American bison* (Bos bison), *to maintain the open short-grass habitats in which it feeds. The Brown-headed Cowbird was confined mostly to the grasslands of the Great Plains of central North America, and is still particularly abundant there. The association with large mammals has enabled this and other cowbird species dramatically to extend their ranges as land has been cleared to provide grazing for livestock. But although domestic cattle have largely replaced bison as the cowbird's foraging associate, the recent restoration of bison in their former territories has increased opportunities for cowbirds to interact with this native grazer. A study in 27,000 ha of short-grass prairie pasture in north-east New Mexico found that female cowbirds breeding in pinyon–juniper* (Pinus–Juniperus) *woodlands commuted an average of 7·24 km to prairie sites to feed during the afternoons. Mean commuting distance was related to distance of the nearest bison from the breeding grounds. Because bison ranged widely over the grassland, females in the bison-grazed landscape commuted farther and had larger feeding areas and overall home ranges than those in areas grazed by cattle. When few bison were within 10 km of the cowbird breeding ranges, cowbirds foraged with wapiti* (Cervus canadensis) *or without ungulates. Dependence on the erratic movements of bison herds could have precluded normal nesting at a fixed site, and has been proposed as the origin of brood-parasitic behaviour by cowbirds.*

[*Molothrus ater artemisiae*, National Bison Range Wildlife Refuge, Moise, Montana, USA. Photo: Donald M. Jones/ DRK]



*Like other oropendolas, the **Amazonian Oropendola** is usually found feeding in the upper strata of trees. Male Amazonian Oropendolas are much larger (average 51 cm, 449·6 g) than females (42 cm, 259·2 g), and the sexes may differ in the foods that they take and the foraging tactics used. In the Montezuma Oropendola* (Psarocolius montezuma)*, females are able to take insects from curled dead leaves near the ends of thin branches. These are inaccessible to the heavier males, which need stronger perches from which to feed.*

[*Psarocolius yuracares yuracares*, Yasuní Research Station, Orellana, Ecuador. Photos: Nick Athanas]

Several members of the family catch insects that accompany grazing mammals. Although interactions with wild herbivores have been reported, it is nowadays mostly domestic livestock that are exploited. The behaviour is particularly common among the parasitic cowbirds, but it has been reported also for other species such as the Nicaraguan Grackle and the Cuban Blackbird. Kleptoparasitism has been reported from the south-east USA, where Boat-tailed Grackles in Florida were seen to steal food from ibises (Threskiornithidae).

Consumption of seeds varies considerably both among and within species, as well as seasonally and geographically. Icterids having a short, finch-like bill are the more granivorous. Seeds reportedly accounted for 88% of the stomach contents of Greyish Baywings in eastern Argentina. Grass seeds and seeds of herbaceous plants are important for open-country icterids, whereas those living in woodland and forest consume seeds of several tree genera. Rusty Blackbirds, for instance, eat acorns (*Quercus*) and pine seeds.

Icterids frequently use a peculiar feeding technique known as "gaping", a method known to be utilized also by some other birds, including corvids and starlings (Sturnidae). The bird, as it searches for hidden food, forcibly introduces its closed bill into the substrate, such as the soil and then, thanks to an elaborate jaw musculature, it opens the bill against the resistance of the substrate,

Although omnivorous, eating small fruits and enough nectar to be a secondary pollinator of the shaving-brush tree (Pseudobombax ellipticum) *in Mexico, **Bullock's Oriole** eats mostly insects. Its stomach contents were found to be 79% animal matter and 21% vegetable. This oriole gleans in foliage and also picks insects from spider webs. Even in the breeding season it can be found foraging in flocks of up to 20 birds. In contrast, the Baltimore Oriole* (Icterus galbula)*, with which Bullock's was once considered conspecific, is rarely social when foraging on its breeding grounds.*

[*Icterus bullockii bullockii*, Crooked River Ranch, Oregon, USA. Photo: Kevin Smith/VIREO]

creating a sort of gap or crevice. In most icterids, the muscles that raise and lower the mandibles, namely the protractors and the depressors, are remarkably strong. Species that feed on the ground, such as the meadowlarks and the marshbirds, employ the gaping technique mostly for extracting soil invertebrates. Arboreal icterids, especially caciques, use gaping as a means of opening up dry or decaying wood, such as small branches and bark, so that they can then extract insects, often carpenter ants (*Camponotus*) and their larvae. A more specialized use of the technique is demonstrated by the Scarlet-headed Blackbird. This icterid inserts its chisel-shaped bill into the vertical stems of water plants, including reeds and species of *Cyperus* sedge and *Thalia* (Marantaceae), opening them in order to extract concealed larvae. The Jamaican Blackbird utilizes gaping to extract prey from epiphytic bromeliads, and Saffron-cowled Blackbirds employ the method to extract small animals from the thorny basal leaves of *Eryngium*, plants that look much like terrestrial bromeliads. Other icterids use gaping as a means of opening pine cones, closed flowers and large fruits. Some species sometimes use the bill in a woodpecker-like fashion to excavate bark and soft wood.

Most members of the family use the feet for holding prey or other food items. Common Grackles feeding on crayfish commonly use this technique. In Argentina, Greyish Baywings frequently grasp masses of thistle seeds (Asteraceae) with the feet, holding them against a perch, and tear apart the non-edible silky pappus. In the same way they have been seen to tear apart large insects and the larval cases of hesperiid butterflies.

Flower nectar is an important food mostly for orioles, and almost all members of the genus *Icterus* regularly visit flowers to obtain it. In the process of drinking nectar, many orioles pollinate the flowers. This mutualistic interaction has been studied in respect of several leguminous trees in the genus *Erythrina*, most of which produce orange, red or crimson flowers. The numerous species of *Erythrina* in the Mexican flora that are adapted to pollination by resident and migratory orioles reflects a past and present abundance of oriole species in Mexico. Flocks of migratory Nearctic orioles, involving mostly Baltimore and Orchard Orioles, are important pollinators of many *Erythrina* species in their winter quarters in Central America. Orioles, like all icterids, usually obtain nectar while perched. Consequently, species of *Erythrina* specialized for oriole pollination produce flowers that can be easily reached by a perched bird; the flowers face towards the trunk and are sited on bare stout branches. Other plants visited by icterids produce red brush-shaped flowers, as illustrated by the showy vine *Combretum fruticosum*. Pollinators of this liana in western Mexico included five species of oriole, particularly the Streak-backed Oriole (*Icterus pustulatus*), and the Mexican Yellow-winged Cacique.

By contrast, in their quest for nectar orioles sometimes damage the flowers pollinated by other animals, thus complicating the reproduction of the plant. In the late dry season in central South America, trees of the genus *Tabebuia* produce masses of pink or yellow blossom, but the flowers are frequently subject to destruction by Variable Orioles, which perforate or slice the corollas with their bills. As these orioles do not form large flocks, the damage to the plant is relatively small.

Caciques and oropendolas regularly visit large flowers, particularly the creamy-white cup-shaped blooms of balsa trees (*Ochroma pyramidale*). In the Chapare province of Cochabamba, in central Bolivia, Crested and Amazonian Oropendolas and the yellow-billed race *alfredi* of the Russet-backed Oropendola, along with Yellow-rumped Caciques, visited flowering balsa trees in large mixed flocks during the early morning hours. Balsa trees are short-lived and found in second-growth vegetation, and they are now abundant in Chapare as a result of deforestation. Their flowers are nocturnal, lasting for less than one day, and are pollinated primarily by bats (Chiroptera). Oropendolas and caciques are able to obtain the nectar remaining at the bottom of the flower only during the early morning, after which the flowers wilt or fall.

Some *Erythrina* species in South America are possibly pollinated by the Crested Oropendola, an assiduous and non-destructive visitor. Recent studies have shown that this oropendola and the Red-rumped Cacique are important pollinators of the flowers of a species of *Mucuna*, a large genus of tropical lianas in the legume family (Fabaceae). In eastern Amazonia, Yellow-rumped Caciques are one of the avian pollinators of the bacuri (*Platonia insignis*), an important tropical fruit tree of the family Clusiaceae. The flowers of this tree are large and pinkish, with numerous stamens.

Flower nectar can be a secondary food source for icterids in other groups, but the role of these birds as pollinators is less well known. Outside the tropics, Austral Blackbirds are reported as

One Cacicus *species, the Golden-winged Cacique* (Cacicus chrysopterus), *has occasionally been noted as catching insect prey on the wing, and an individual of this species was described as "extremely vigorously engaged in catching termites (alates) [Isoptera] out of the air". But there are likely to be few opportunities for sallying within the foliage, where these large passerines do most of their foraging. More typically of the genus, the* **Scarlet-rumped Cacique** *probes into crevices, bromeliads, dead leaves and similar substrates in search of insects. Despite its substantial size and weight, this species is quite acrobatic and often hangs upside-down while foraging.*

[*Cacicus microrhynchus pacificus*, San Isidro Lodge and Reserve, Ecuador. Photo: Barry Miller/VIREO]

*The **Rusty Blackbird** often wades in shallow water to catch prey. It plunges its bill, and occasionally its whole head, into the water after insect larvae, crustaceans including crawfish (Astacoidea), molluscs and even the occasional fish. Rusty Blackbirds also probe in the mud at the water's edge. On drier land, they flip leaves with the bill in search of arthropods and small vertebrates. The Rusty Blackbird's dependence on wooded wetland and wet woodland habitats may explain why, while other North American blackbird species are expanding their ranges and numbers as a result of anthropogenic changes to the landscape, this species is in long-term decline.*

[*Euphagus carolinus*, New Jersey, USA. Photo: Scott Whittle]

taking nectar from the huge, stiff inflorescences of the bromeliad *Puya* in Chile. In Argentina, the nectar of introduced Australian trees such as *Eucalyptus globulus* and *Grevillea robusta* is consumed by Red-rumped Caciques, Greyish Baywings, Chopi and Chestnut-capped Blackbirds, and even Shiny and Screaming Cowbirds. Other parasitic cowbirds, such as the Giant and Bronzed Cowbirds, may visit flowers of *Erythrina* and those of the flame vine *Combretum fruticosum*.

Tree sap has been reported as an unusual food item for the Variable Oriole in the Argentinian Chaco. The oriole simply exploits the sap flowing from holes excavated by White-fronted Woodpeckers (*Melanerpes cactorum*) in three species of tree. This food item seems to be used only during the austral winter, when alternative food resources are scarce.

So far as is known, no icterid is entirely frugivorous, although fruits such as berries do figure in the diet of most species.

*More aquatic than other marsh blackbirds, the **Unicolored Blackbird** catches small fish and tadpoles near the water surface, often perching on floating vegetation such as water-cabbage* (Pistia). *It also picks prey from the undersides of floating leaves. As well as fish up to 3 cm long, beetles (Coleoptera) and dipteran flies, its stomach contents have included 50% seeds, such as those of aquatic grasses, and maize and other cereals from fields surrounding the marshes. Other regular fish-eaters in the family include Common* (Quiscalus quiscula) *and Boat-tailed Grackles* (Q. major), *which catch fish both by wading and by plunging from the air.*

[*Agelasticus cyanopus cyanopus*, Pantanal, Mato Grosso, Brazil. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

The mass spawning of horseshoe crabs (Limulus) *provides an irresistible opportunity for the* ***Boat-tailed Grackle*** *to eat the eggs, and overturned and helpless adult crabs, too. Rusty Blackbirds* (Euphagus carolinus) *also have been seen to gorge on this briefly abundant food source. Other invertebrates taken by Boat-tailed Grackles include marine and aquatic molluscs, shrimps (Caridea) and crayfish (Astacoidea). These grackles prey on the eggs and chicks of many bird species. They readily eat carrion and are said to pick pieces of flesh from trapped muskrats* (Ondatra zibethicus).

[*Quiscalus major torreyi*, Delaware Bay, New Jersey, USA. Photo: Doug Wechsler/ VIREO]

Oropendolas are probably the most frugivorous members of the family, and the stomach contents of many individuals in this group have been found to consist solely of fruit pulp. In late August, Montezuma Oropendolas on the Caribbean coast of Costa Rica consumed fruits of at least six species of tree and palm, including cultivated plants such as pejibaye palms (*Bactris gasipaes*) and African akees (*Blighia sapida*). Similarly, the Golden-winged Cacique consumed fruits of at least five plants in a forest in the Brazilian state of São Paulo, and in Argentina this species feeds also on cactus fruits and those of spiny terrestrial bromeliads. Jamaican Orioles (*Icterus leucopteryx*) consume the fruits of at least seven native plants. At the northern end of the family's range, in the boreal forests of North America, Rusty Blackbirds consume berries of several species, such as American holly (*Ilex opaca*) and flowering dogwood (*Cornus florida*). At the opposite geographical extreme, in the southern beech (*Nothofagus*) forests, Austral Blackbirds frequently feed on berries of maqui (*Aristotelia chilensis*).

In Quintana Roo, in south-east Mexico, several tree species may germinate from faecal matter deposited by Montezuma Oropendolas. Overall, however, the role of frugivorous icterids as seed-dispersers remains almost unknown and requires extensive study.

The extreme sexual size dimorphism of such icterids as the Montezuma Oropendola suggests that the sexes may differ in the foods that they take and the foraging tactics used. Webster found that female oropendolas searched for hidden prey in aerial litter far more frequently than males. In the Costa Rican forests, such aerial litter in the form of dry curled leaves accumulated mostly at the tips of rather thin branches, a fact that precluded its use by the heavier males.

The little-known ***Southern Mountain Cacique*** *is thought to be mainly insectivorous, but also takes some fruit and nectar. Caciques have been seen to swallow fruit up to the size of small figs* (Ficus), *and thereby act as seed-dispersers, but they mandibulate and discard the seeds of larger figs. Two* Cacicus *species which occupy the same Atlantic Forest reserve in south-east Brazil were found to differ in their seasonal diets. The Red-rumped Cacique* (Cacicus haemorrhous) *and the Golden-winged Cacique* (C. chrysopterus) *both ate fruit and arthropods, but the Red-rumped switched largely to fruit in the wet season, while the Golden-winged remained primarily insectivorous all year.*

[*Cacicus chrysonotus*, Manu road, Cusco, Peru. Photo: Andy & Gill Swash/ WorldWildlifeImages.com]

Breeding

It is possible that no other passerine family in the Americas surpasses the Icteridae in the variety of its breeding and nesting habits. Parental investment ranges from the very minimum, as shown by the parasitic cowbirds, to the extremes demonstrated by the oropendolas, which spend weeks in weaving elaborate nests and, afterwards, months of nestling and post-fledging care.

The variability starts at the level of nest dispersion. Most orioles nest solitarily, but the Orange Oriole (*Icterus auratus*) of the Yucatán Peninsula often breeds in colonies of up to 35 nests. An intermediate stage, the dispersed colony or semi-colony, is presented by Bullock's and Orchard Orioles in North America, and possibly by related Neotropical species, too. The caciques are mostly solitary nesters, like the orioles, but colonies of Red-rumped and Yellow-rumped Caciques can contain more than 100

Wild fruits eaten by the ***Baltimore Oriole*** *include the berries of* Rubus, Prunus *and* Amelanchier *species on its breeding grounds, and* Bursera simaruba *arils and* Cecropia *"catkins" on the wintering grounds. Baltimore Orioles also take orchard crops such as grapes and cherries, and puncture the skins of large fruits such as oranges and banana to get at the pulp and juice. Although they cause some damage to commercial fruit crops, they also consume large numbers of pests, including* Malacosoma *tent caterpillars. The different techniques used by Baltimore Orioles and Yellow-backed Orioles* (Icterus chrysater) *to handle* Bursera simaruba *fruits were compared in Panama. Baltimore Orioles removed the pulp from the nutlet, which they usually dropped on the ground, whereas Yellow-backed Orioles left them on the tree. The two orioles were slow and inefficient compared with other icterids feeding on the same fruit, including an oropendola* (Psarocolius) *and a cacique* (Cacicus), *which both swallowed the fruits whole and had much shorter handling times and higher feeding rates. It was suggested that fruit is important for caciques and oropendolas, but that orioles' consumption of fruit is more opportunistic and that efficient handling of fruit is less important for them.*

[*Icterus galbula*, Texas, USA. Photo: Rolf Nussbaumer/ naturepl.com]

There are few detailed data on the diet of the ***Scrub Blackbird****. Along with insects and seeds, its stomach contents have contained fruit pulp, including cultivated mangoes* (Mangifera). *The Melodious Blackbird* (Dives dives), *with which the Scrub Blackbird was previously considered conspecific, is a frequent and assertive member of mixed groups at fruiting trees. Both species forage mainly on the ground and make much use of a technique known as "gaping", which is common among icterids. They push the closed bill into a substrate such as soil or bark, or between the scales of pine cones* (Pinus) *or leaves of bromeliads, then force the mandibles apart with the powerful jaw muscles to create a gap from which prey can be extracted.*

[*Dives warczewiczi warczewiczi*, Buenaventura, Ecuador. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

nests, and both may breed in such thick clusters that some interweaving of neighbouring nests occurs. Solitary nesting is exceptional among oropendolas, but colony sizes and the degree of nest clumping vary among species. The largest oropendolas, such as the Montezuma Oropendola, often form discrete clusters of nests within the colony.

Quiscaline blackbirds range from being solitary nesters to forming some of the largest breeding aggregations reported for any passerine species. Tricolored Blackbird colonies of 100,000–300,000 nests were reported in California in the 1930s and 1940s, although nowadays the species is much less abundant. Most meadowlarks and allies nest solitarily or in semi-colonies, the largest aggregations having been reported for the Yellow-headed Blackbird, with several hundred nests.

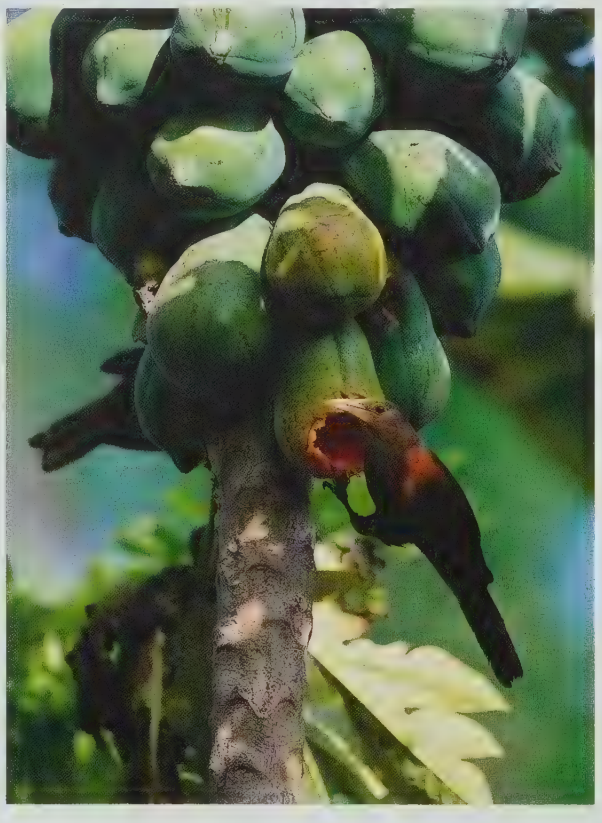
Colonial icterids may not defend all-purpose territories, and they often obtain their food in undefended spaces away from the colony, while foraging in groups or flocks. Clumped nests easily attract predators, and the ideal colony sites would be appear to be those located in safer places such as tall isolated trees, small islands, or even swamps. Orioles, caciques and oropendolas not infrequently nest near aggressive insects, such as wasps (Vespidae) or ants, that deter climbing predators, or they share the nest tree with birds, such as some jays or tyrant-flycatchers, that are aggressive to hawks and other avian predators. Sometimes humans play the role of nest guardians, as some caciques and oropendolas breed near buildings or within towns.

Caciques and oropendolas will also nest in mixed colonies, with nests of two or more species in the same tree or in neighbouring trees. Mixed colonies of Red-rumped and Yellow-rumped Caciques occur in parts of northern Amazonia, and were studied by Feekes in Suriname. Similarly, oropendolas, particularly the Crested, Green and Amazonian Oropendolas, have been reported as nesting in mixed colonies. Some races of the Russet-backed Oropendola form mixed colonies with Crested Oropendolas and/ or Yellow-rumped Caciques. On the other hand, some Russet-backed populations, such as the nominate race in lowland Amazonian Peru and *alfredi* in central Bolivia, are reported to be aggressive, even predatorial, towards Yellow-rumped Caciques and other breeding oropendolas, and therefore nest more commonly in separate, single-species colonies.

The benefits and disadvantages of mixed colonial nesting are not well understood, and warrant more study, ideally by comparing reproductive success for each species in single-species colonies with that in mixed colonies. A scarcity of large isolated trees, including trees with aggressive wasps or growing in unusual safe sites, is probably the main reason for mixed colonial nesting. Once the mixed colony is founded, the different species may help each other in producing alarm calls, or in detecting nest predators. Caciques and oropendolas, however, are seldom as aggressive in mobbing or deterring predators as some tyrant-flycatchers. Disadvantages of mixed colonies include increased food competition in the neighbourhood of the nesting trees and, probably, an increase in the stealing of nest materials by females of the different species. These two factors should affect the smaller species, the caciques, more strongly. Perhaps small mixed colonies are beneficial in pristine areas, where oropendolas and caciques are naturally scarce, but much less so in human-modified areas, where their numbers have increased.

A few orioles may nest together in the same tree, particularly in southern Mexico and Central America when using acacia (*Acacia*) species that harbour aggressive ants. Solitary orioles of two species sometimes nest within the colonies of Orange Orioles in Yucatán. Mixed colonies of marsh-nesting North American icterids are reported. Red-winged and Yellow-headed Blackbirds, however, interact negatively when breeding, the large Yellow-headed aggressively displacing the smaller Red-winged Blackbirds from the deeper nesting marshes. Boat-tailed and Great-tailed Grackles will form mixed colonies in the small area where their ranges overlap in North America. In South America, Saffron-cowled and White-browed Blackbirds can sometimes be found nesting together in semi-colonies in patches of grassland.

Icterid mating systems cover all the possibilities from monogamy to polygamy, including promiscuity. Monogamy is probably the commonest system in the family, being typical for the majority of orioles, and also for several quiscalines, particularly



A number of Icterus *species include cactus fruits in the diet, but their visits to these fruits are usually brief. Apart from the nutrient content, which is relatively low for its bulk, the juicy pulp may be an important source of water in arid environments. The* ***Black-vented Oriole*** *opens up the fruits by pecking through the skin, then swallows the pulp, leaving or discarding the seeds. In Guatemala, an Altamira Oriole* (Icterus gularis) *was seen to pluck and toss away several areoles (the clusters of spines emerging from bumps on the skin of the fruit) before eating the pulp, and two Streak-backed Orioles* (I. pustulatus) *were seen to eat simultaneously from the same cactus fruit.*

[*Icterus wagleri wagleri*, Jaumave desert, NE Mexico. Photo: Claudio Contreras/ naturepl.com]

in the Neotropics, and for the solitary-nesting caciques. Polyandry seems to be rare, but it may exist among species indulging in co-operative breeding. Polygyny is widespread within the family, but only the oropendola genus *Psarocolius* is fully polygynous. A limited form of polygyny is practised by the non-territorial Brewer's Blackbird, whereby a minority of males may each consort with two or three females nesting within a breeding colony. The simplest type of polygyny is successive, or serial, polygyny, in which males have several short-term monogamous bonds during a breeding season. In this system a male consorts with a female only during the nest-building and egg-laying periods, deserting the fertilized female and its nest when incubation starts and copulations are no longer needed. Successive polygyny is recorded for colonially nesting Yellow-rumped and Red-rumped Caciques, several oropendola species, the Nearctic and Neotropical quiscalines, and polygynous meadowlarks, including the Bobolink. In harem polygyny, the male defends a space or territory in which several females are nesting simultaneously. This system is practised by such species as the Montezuma Oropendola and the Boat-tailed and Great-tailed Grackles, and by many populations of the Red-winged Blackbird. Males of this last icterid have harems containing two to 33 females. Detailed studies with colour-marked individuals have shown that males of some oropendolas and grackles may switch from successive polygyny to harem polygyny, depending on the temporal availability of unmated females.

Promiscuity occurs when the sexes meet only during copulation, no pair-bond being formed. It has been reported for Brown-headed and Shiny Cowbirds, but cowbird mating systems are variable, even within species. The cowbirds include a rather strict monogamist in the form of the Screaming Cowbird. Extra-pair copulations, a hidden form of promiscuity, were first reported for Red-winged Blackbirds. Males of this species nesting in large colonies practise a visible haṛem polygyny, but the harem females are unfaithful and copulate with neighbouring males, or with outside males of lower social status. This fact was discovered when the high-ranking harem masters were sterilized as a form of population control, but fertile eggs were still produced in the colony. Extra-pair copulations occur among other colonial-nesting icterids, such as Montezuma Oropendolas and Boat-tailed and Great-tailed Grackles, but the best tool for its detection, genetic fingerprinting of eggs and chicks, has been carried out on only a limited number of species.

Many male icterids, in several genera, have a perched courtship display in which the head is lowered, the body feathers raised, and the wings and tail opened and spread. Because a song is simultaneously produced, this display is often named the "Song Spread", but such names as "Ruff-out" or "Bow" are also used. It is performed by many quiscalines and caciques and, in particularly exaggerated form, by the larger oropendolas, but the dis-

Oropendolas (Psarocolius) *are probably the most frugivorous members of the Icteridae, and the stomach contents of many individuals in this genus have been found to contain nothing but fruit pulp. In Chapare, in Bolivia, the race* alfredi *of the* ***Russet-backed Oropendola*** *feeds on many cultivated fruits, from oranges to papayas* (Carica). *The birds break through the papaya's skin by thrusting in their bill and gaping, then eat the pulp until only a bell-shaped fragment of the empty skin is left.*

[*Psarocolius angustifrons alfredi*, Madidi National Park, Bolivia. Photo: Luiz Claudio Marigo]

Nectar from the flowers of trees of the genus Erythrina *is an important food source for many icterids, including the* ***Crested Oropendola****. Despite its large bill, the Crested Oropendola manages to remove the nectar without damaging the flowers, and this species may be an important pollinator, perhaps even the primary pollinator, of some species of* Erythrina. *In a dry forest in western Brazil, the Crested Oropendola was the second most regular visitor to the flowers of* Erythrina dominguezii, *after the Yellow-chevroned Parakeet* (Brotogeris chiriri), *which destroyed the flowers while consuming the nectar.*

[*Psarocolius decumanus decumanus*, San José de Chiquitos, Santa Cruz, Bolivia. Photo: Daniel Alarcón]

play appears to be given only very rarely by some other species, such as the Greyish Baywing.

Parental duties of both sexes follow rather simple rules in this family. With the vast majority of icterid species, it is the female alone that builds the nest. Males of some monogamous species may help in the task of nest-building, and in the case of a few species, the Melodious Blackbird being one example, the sexes may do more or less equal shares of the work. Nest-building mostly by males is a characteristic of two closely related South American blackbirds that nest in marshes, the Chestnut-capped and Yellow-hooded Blackbirds. Males of both species build several nests that may be accepted and completed by different females. Lastly, parasitic cowbirds, as they lay in the nests of other birds, do not, of course, build nests of their own.

Icterids are one of very few passerine families that construct pensile nests, the best-known family being the weavers (Ploceidae) of Asia and Africa. Nest-weaving is a complex process, involving a careful selection of fibrous materials, a series of movements for interlacing the material into a resistant fabric, and the firm attachment of the structure to a branch or leaf. Detailed studies by V. H. Schaefer revealed that weaving skills are affected by experience, but weaving behaviour probably involves a strong genetic component. Woven pensile nests are found only in two icterid clades, the orioles being one and the caciques and oropendolas the other, which might (or might not) reflect common ancestry.

The nests of orioles are far more heterogeneous than those of caciques and oropendolas. Some oriole species, such as Scott's Oriole, may build semi-pensile nests, attached to lateral branches or other vegetation. The structures woven by most tropical and subtropical small orioles in the "*Bananivorus* or *Pendulinus* group" (see Systematics) are shallow bags stitched to the underside of palm leaves. Only some of the larger orioles construct elongated pendent nests that closely resemble those of caciques and oropendolas.

Within the orioles, the three troupials show a clear trend towards the abandoning of nest-building. As shown by C. A. Lindell and C. Bosque in their study in Venezuela, different troupial populations display a remarkable gradation in nesting habits, from conventional nest-building to almost obligate nest piracy. Only in the coastal race of the Venezuelan Troupial does nest-building co-exist with the use of other birds' nests. The two other troupial species seem have lost the habit of nest-building entirely, and usually usurp the covered nests built by furnariids and by other icterids such as caciques. The many types of nest built by the orioles would suggest that the weaving of pensile nests has actually evolved independently in the oriole clade and the cacique–oropendola clade.

All known nests of caciques and oropendolas have been pendent elongate bags, almost invariably placed in trees. The Dusky-green Oropendola (*Psarocolius atrovirens*) is the exception, as it often suspends its nests from cliffs in the Andes, a habit first described by G. Niethammer, in 1956. The nests of true oropendolas, those in the genus *Psarocolius*, are relatively uniform in shape and materials, but those of *Cacicus* caciques vary in size, shape and materials, probably reflecting the polyphyly of this group. The Golden-winged, Ecuadorian and Selva Caciques weave nests mostly with dark fibres of the fungus *Marasmius*, a habit that seems to reflect the close phylogenetic relatedness among them (see Systematics).

Nests of most quiscaline blackbirds are open cups built with interlaced plant material, often reinforced with an inner coating of mud. A few nests of the little-known Velvet-fronted Grackle are unusual in each being a deep pouch suspended over water, but the available information is preliminary and incomplete. The habit of nesting in tree holes, rare among icterids, has been reported for Common Grackles in North America. Hole-nesting is more frequent among Yellow-shouldered Blackbirds (*Agelaius xanthomus*) in Puerto Rico, and in South America among the baywings and the Chopi Blackbird. The last-mentioned species also occupies covered nests build by other birds, again mostly furnariids. Two icterid populations nest in holes in cliffs. One is a population of Yellow-shouldered Blackbirds breeding in the sea cliffs of Mona Island, in the Caribbean between Hispaniola and Puerto Rico, and the other is the Bolivian Blackbird, found only in dry Andean valleys.

Meadowlarks build a cup-shaped nest of grass and stems on the ground, where the structure is hidden by dense vegetation. The nests may be further covered by a dome of looser plant material. Bobolink nests follow this pattern. The marsh-nesting Yellow-headed Blackbird, however, builds a neat cup-shaped nest over deep water, in aquatic plants or in nearby willows (*Salix*).

Icterid eggs exhibit considerable variation in size, shape and colour. As with other passerine families, there is a positive correlation between egg size and the size of the laying female. The eggshells of the parasitic cowbirds are particularly thick. Although the eggs of some species are unmarked white or bluish-white, most icterid eggs are spotted and blotched in shades of brown, purplish-brown and blackish. Irregular curved blackish lines, described as "curls" or "scrawls", are typical of many icterid eggs.

Clutch size ranges from one to six eggs, occasionally more. Single-egg clutches are generally rare, but are reported fairly often for the Dusky-green Oropendola of the Bolivian and Peruvian highlands. Clutches of two eggs are produced mostly by colonial-nesting caciques and oropendolas, species found in the tropics and subtropics. A. Cunningham and S. Lewis reported that, although Montezuma Oropendolas commonly lay two eggs, they usually raise only one chick, and this has been recorded for other species, as well.

Incubation is undertaken by the female alone, and she is sometimes fed on or near the nest by her mate. Males of the Rusty Blackbird and the two marshbirds, for example, commonly feed the sitting female, and Brewer's and Saffron-cowled Blackbirds do so at least occasionally. The incubation period for most members of the family is in the range 11–15 days, frequently 12–14 days. In the case of the larger caciques and oropendolas, however, it is longer, lasting for 17–19 days, while the female Russet-backed Oropendola incubates for 19–20 days. With most icterid species, the nestlings are fed by both parents. Exceptions to this general rule include the polygynous oropendolas, in which the females take on the responsibility of chick-feeding, as well as the tasks of nest-building and incubation of the eggs. Similarly, the nestlings of the Boat-tailed Grackle, the Red-winged, Yellow-hooded and Chestnut-capped Blackbirds and the meadowlarks are provisioned mostly or exclusively by the female parent. Among co-operative breeders such as the Red-bellied Grackle and Chopi Blackbird, the parents are usually assisted by helpers in the feeding of the nestlings. The chicks of most icterids remain in the nest for a period ranging from about 10 days to 14 days, varying with species, but the young of some, such as the Bobolink, leave the nest after only nine days. In contrast, others, such as the Chopi Blackbird, depart when 16–18 days old. The nestling period of some *Quiscalus* grackles and the Venezuelan Troupial is significantly longer, lasting for up to at least 23 days, and that of some caciques is up to 28 days, while some young Russet-backed Oropendolas do not leave the nest until 32 days of age, some Crested Oropendolas only at 34 days, and chicks of Chestnut-headed and Montezuma Oropendolas not until 35 days.

Within the Icteridae, six species of cowbird are obligate brood parasites. Parental care by the female parasite is reduced to the forming of the eggs, followed by the finding of nests of appropriate hosts and depositing the eggs in these. Cowbird eggs are incubated, and the chicks reared, only by the host. Parental care by male cowbirds may be non-existent, or may consist only of helping the female, either by finding nests or by distracting or attacking host individuals. This last type of behaviour has been reported mostly for Giant Cowbirds.

It is possible that cowbird parasitism was known to the original native American peoples. People living in rural areas today are aware of its existence, and some popular Spanish and Portuguese names for the Shiny Cowbird make reference to the species' parasitic lifestyle. Nevertheless, cowbird parasitism was first described by the Spanish naturalist F. de Azara in his famous book on the birds of Paraguay and Río de la Plata, published during 1802–1805. Apparently, most of Azara's information on cowbirds was obtained by his friend and informant Father Pedro Noseda, priest at the mission of San Ygnacio Guazú, in Paraguay. Research on cowbird brood parasitism has increased enormously since then, but it is on the Shiny and Brown-headed Cowbirds that most data have accumulated.

Specialization in cowbird parasitism is usually measured in terms of the number of host species in whose nests cowbird eggs have been reported. The most specialized is the Screaming Cowbird, with only three known regular hosts, all them icterids of the South American quiscaline group. This species' main host in most of Argentina and Uruguay is the Greyish Baywing, but the Chopi Blackbird is possibly more important in Paraguay and Brazil; less significant is the Brown-and-yellow Marshbird. The Giant Cowbird is known to parasitize seven species of icterid, all colonial-nesting caciques and oropendolas. In addition, it has been recorded parasitizing two jay species, but the evidence is complete only for the Green Jay (*Cyanocorax yncas*), and two records of Giant Cowbird parasitism on large orioles in Nicaragua likewise require further evidence. The number of known hosts for the Giant Cowbird could thus increase to eleven species. The two more specialized cowbirds seem not to be so numerous as the generalist species, but Screaming Cowbirds are relatively common in central Argentina and are currently expanding their range in Brazil.

The Bronzed Cowbird is less specialized, and its eggs have been found in the nests of more than 80 species of passerine birds of several families, including Icteridae. The breeding biology of the closely related Bronze-brown Cowbird, however, is almost unknown. Both Shiny and Brown-headed Cowbirds are extreme generalists, with 200 or more species of known hosts. Of course, the hosts of generalized cowbirds include members of numerous bird families, but non-passerines are seldom reported as victims. Important host families for Brown-headed Cowbirds include tyrant-flycatchers, vireos (Vireonidae), New World warblers and New World sparrows. In South America, Shiny Cowbirds lay in the nests of furnariids, tyrant-flycatchers, mockingbirds (Mimidae), thrushes (Turdidae), icterids and New World sparrows. Acquisition of new host species has been well documented for the Brown-headed and Shiny Cowbirds, as both species have colonized new areas in historical time.

The DNA phylogeny indicates that parasitic cowbirds are a monophyletic group (see Systematics), and therefore brood parasitism evolved only once in the Icteridae. Several ideas have been advanced with regard to how cowbirds became parasites. The parasitic cowbirds are inserted within the North American quiscaline clade, even if the molecular data suggest that the Screaming Cowbird, a South American species, is possibly the

*Where the **Western Meadowlark** and the Eastern Meadowlark* (Sturnella magna) *overlap in range, the Western prefers drier habitats. But it still needs to drink, making use of ephemeral puddles and tanks supplied for livestock (where it occasionally drowns). Lilian's Meadowlark* (S. lilianae) *lives in even more arid environments and was for long regarded as a desert-adapted form of Eastern Meadowlark. No icterids are found in extreme deserts, such as the Atacama or the high-altitude* punas *of the central Andes. Even the Scrub Blackbird* (Dives warczewiczi), *which lives along the almost rainless coast of Peru, is found mostly at oases or watercourses, or around irrigated farmland. In semi-arid regions, icterids such as orioles obtain much of the water which they require from their food, including fruit and nectar.*

Many male icterids perform the perched display known as the "Song Spread", shown here by the ***Greater Antillean Grackle****. The Common Grackle* (Quiscalus quiscula) *performs this display at greatest intensity early in the season, while pair-bonds are still being formed. Male grackles also direct the Song Spread at other males. In the Common and Carib Grackles* (Q. lugubris), *females, too, perform the display, though never with the same intensity. Various elements of the display, such as the depth of the bow and whether the plumage is raised or sleeked, differ among species and genera.*

[*Quiscalus niger brachypterus*, Cabo Rojo, Puerto Rico. Photo: Eladio M. Fernández]

oldest extant species of parasitic cowbird. The fossil record does not contradict the notion that parasitic cowbirds first evolved in North America, as several species of extinct cowbird-like icterid are known from the Upper Pleistocene of the USA (see Systematics). Speculation on the origin and evolution of brood parasitism by cowbirds can be tested with the new DNA phylogeny.

One set of hypotheses assumed that the Greyish Baywing was the ancestor of the parasitic cowbirds, and that parasitic cowbirds first evolved in South America. This hypothesis was first advanced by W. H. Hudson, in 1920. Hudson selected the Greyish Baywing as the ancestor for two main reasons: it often breeds in other birds' nests, and it looks quite cowbird-like in its external morphology. He suggested that a progressive decay of the parental instincts occurred in this lineage, starting with the loss of nest-building behaviour. He also discovered that Screaming Cowbirds were parasitic on Greyish Baywings and that chicks of the two species were remarkably similar in plumage and voice. Hudson reasoned that the chick resemblance was a shared ancestral character, and therefore a proof of the common origin of the two species. The alternative idea, that chick resemblance between host and parasite was due to mimicry, was rejected on the grounds that chicks of most brood parasites do not resemble host chicks and yet receive parental care from their foster parents.

H. Friedmann, in 1929, expanded Hudson's ideas and placed them in an evolutionary frame. He presented a cowbird phylogeny in which the Greyish Baywing occupied the ancestral position, giving origin to the Screaming Cowbird, the first parasitic cowbird. A behavioural imbalance between nest-building and egg-laying instincts, even if mediated by hormone imbalance, would have occurred during the evolution of parasitic habits in this lineage. Friedmann's views became textbook classics, and few authors since then have questioned their importance.

More recently, in 1996, A. F. Skutch elaborated a hypothesis also based on Hudson's and Friedmann's views. For Skutch, however, the main factor responsible for the evolution of brood parasitism was intense competition between closely related icterids for the use of closed nests or nesting cavities. The competitors would be the Greyish Baywings and the ancestral Screaming Cowbirds. The less aggressive species, in his view the Screaming Cowbird, evolved parasitism on the most successful competitor, the Greyish Baywing.

The traditional view of baywings as ancestors of the parasitic cowbirds collapsed when Lanyon, in 1992, showed that baywings were not closely related to the Screaming Cowbird, or to any other parasitic cowbird. Mitochondrial DNA indicated that baywings are members of the South American quiscaline icterids, whereas *Molothrus* belongs with the North American quiscalines. The close resemblance, in plumage and voice, between baywing chicks and Screaming Cowbird chicks turned out to be a remarkable case of mimicry.

If cowbirds are of Nearctic origin, an old hypothesis on the origin of cowbird parasitism, posited by O. Widmann in 1907, becomes worthy of reconsideration. Widmann's hypothesis was based on the foraging dependence of all extant parasitic cowbirds on grazing mammals. It is widely believed that in pre-European times Brown-headed Cowbirds followed the large nomadic herds of grazing American bison (*Bos bison*) on the North American prairies, seizing insects disturbed by the mammals, and this they still do in some bison reserves. Cowbird dependence on such a mobile and erratic source of food could have precluded or impeded normal nesting at a fixed site. Recent studies of Brown-headed Cowbirds in a bison reserve found that radio-tracked females commuted an average daily distance of seven kilometres from their breeding grounds to the bison herds. This daily movement probably had an adverse effect on egg formation and egg deposition by the cowbird females. Ancestral cowbirds may have evolved parasitism in order to circumvent this constraint. As intermediate strategies between parasitic and non-parasitic breeding do not occur among living icterids, most ideas on the origin of parasitism will perhaps remain untested.

Adaptations of cowbirds to parasitic breeding are not very many. Female cowbirds have been called "passerine chickens", because they produce far more eggs per season than "normal-breeding" icterids. Cowbird eggs are variable, but, unlike those of parasitic cuckoos (Cuculidae), they seldom match the eggs of particular hosts. Moreover, chicks of the generalist cowbirds do not resemble host chicks in appearance or behaviour. Screaming Cowbird chicks mimic those of the species' main host, the Grey-

ish Baywing, but chicks of Screaming Cowbirds parasitizing other hosts do not mimic the latter's chicks. The Giant Cowbird chick is unique in having a well-developed pale frontal casque that perhaps mimics that of its oropendola nestmates.

An important report by N. G. Smith, published in 1968, presented information suggesting a mutualistic interaction between Giant Cowbirds and their hosts the Yellow-rumped Cacique and the Chestnut-headed Oropendola in Panama. The host nests were sometimes subject to severe infestation by ectoparasitic flies of the genus *Philornis*, which caused host-chick mortality. When Giant Cowbird chicks were present, however, they were able to remove the fly larvae from both themselves and their nestmates. In such cases, the cowbird chicks were beneficial to their hosts. Giant Cowbird adults, and their eggs and chicks, were accepted in *Philornis*-infested colonies, but not in others. Presence or absence of these flies in a colony was somehow related to the presence or absence of some wasp nests in the colony. Although details of this possible mutualism were correct, such as the chick mortality caused by the flies, the information was not confirmed elsewhere. Studies in Peru and Costa Rica revealed other host species to be invariably aggressive towards Giant Cowbirds. In Misiones, in north-east Argentina, Giant Cowbird chicks can be severely infested by botflies.

Cowbird parasitism is almost invariably detrimental to the hosts. Cowbirds, while laying their own eggs, typically remove those of the host or puncture them with their sharp bill. Cowbird eggs have short incubation times, only 10–12 days, and commonly hatch before the surviving host eggs do. Because of this earlier start, cowbird chicks can easily outcompete host chicks and cause them to starve, although this is not always the case with chicks of very large hosts.

As would be expected, many cowbird hosts have evolved defences to combat parasitism. These include aggression against cowbirds approaching the nest, and, more remarkably, the ability to remove cowbird eggs from the nest. Species that remove cowbird eggs were termed "rejecters" by S. Rothstein, who performed many elegant experiments on the subject; "accepter species" are those that incubate the cowbird's eggs. Among North American birds, the rejecters usually have a long bill and are able to carry the cowbird eggs away from their nests. Successful rejecter species are now seldom molested by cowbirds. Accepter species may survive simply through their sheer numbers and extensive distributions, as illustrated by the Rufous-collared Sparrow (*Zonotrichia capensis*). For accepter species that face conservation problems, however, cowbird parasitism can be an additional cause of population decline. In the USA, Brown-headed Cowbird populations are subject to local control (see Status and Conservation) in order to protect the most sensitive species, such as Kirtland's Warbler (*Dendroica kirtlandii*).

Co-operative breeding could be seen as the reverse of brood parasitism, as it involves the participation of individuals other than a mated pair in the feeding and care of the young. These additional individuals, commonly known as "helpers", may take part also in other parental duties, such as nest-building, feeding of the incubating female, incubation of the eggs, nest-guarding, and the mobbing of potential predators. Co-operative breeding by icterids was first recorded for Greyish Baywings, by R. Fraga in 1972, and has been reported so far for 16 species in nine genera of South American quiscalines, all belonging to the same lineage. Recent information, unfortunately incomplete, suggests that the Selva and Ecuadorian Caciques may have helpers at the nest. Two nests of the former species in Amazonian Peru were attended by unmarked trios of unknown sex, which visited nests from the start of the nest-building stage. Although, in both cases, nest-building was performed by possibly one member of the trio, the other individuals entered or inspected the nest. The trios co-operated in attacking other birds, mostly other caciques and oropendolas, around the nest-site. In the case of the Ecuadorian Cacique, during a shorter period of observation, several individuals were seen around one active nest.

The available data confirm the suspicions of Orians that co-operative breeding is particularly frequent among South Ameri-

The Song Spread display is exhibited in its most exaggerated form by the oropendolas. This ***Russet-backed Oropendola*** *is giving the display at highest intensity. These birds may also barely raise the wings, or raise them without spreading them, with little more than a cursory bob. The song given during the displays is both shorter, at 0·7–1·7 seconds, and simpler than that of most of its congeners, but it is individually and regionally variable. In the Montezuma Oropendola* (Psarocolius montezuma), *the male falls forward and hangs momentarily from the perch with tail raised and wings spread, giving a brief, incongruously squeaky call.*

[*Psarocolius angustifrons alfredi*, Amboró National Park, Santa Cruz, Bolivia. Photo: Daniel Alarcón]

*The **Yellow-headed Blackbird** nests in reedy marshes in semi-colonies of grouped male territories. Each male defends a territory of 100–600 m², to which the more successful attract a number of females (up to eight have been recorded). The male arrives on the breeding grounds first and, when the female appears, he greets her with a version of the Song Spread display, which is used also in agonistic encounters with other males. This display as performed by this species is said to be asymmetrical, with the right wing held out to a greater extent, and the head and neck turned to the left, so that the bird sings over its left shoulder (lower left photo). The wings are held at their highest at the climax of the song. Other courtship displays include ritualized nest-building movements by the male. During this period the male may chase the female aggressively, pecking and seizing hold of her. The males play no part in the building of the nest itself, but do share in the work of feeding the young. Males of this blackbird expel the smaller Red-winged Blackbird* (Agelaius phoeniceus) *from prime nesting sites in the deep-water marshes.*

[*Xanthocephalus xanthocephalus*, Mono Lake basin, California, USA. Photos: Marie Read]

*The **Giant Cowbird** is a known brood parasite of two colonial species of cacique, the Red-rumped* (Cacicus haemorrhous) *and Yellow-rumped Caciques* (C. cela)*, and at least five species of oropendola* (Psarocolius). *This female Giant Cowbird was inspecting the nest of a Red-rumped Cacique in late afternoon, only to find the owner in residence. Male Giant Cowbirds are reported as sometimes attacking or distracting potential host birds. The Giant Cowbird chick is unique in having a well-developed pale frontal casque that perhaps mimics that of its oropendola nestmates.*

can icterids. No members of the North American quiscaline clade are known to breed co-operatively. Among North American icterids, helping behaviour has been reported mostly for the Bobolink: extra males have been found to feed the chicks in a few nests of this species.

Co-operative breeders in avian families that are better studied than Icteridae have several things in common, notably delayed breeding by both sexes, permanent presence of juveniles in the parental group or territory, and tolerance of extra individuals by the breeding pair, at least during the nestling period. As with social insects, kinship between group-members and chicks is frequent among co-operative breeding birds, allowing for the operation of kin selection. For elucidating the finer details of co-operative breeding, long-term studies of individually marked birds are needed. Nevertheless, Greyish Baywings have delayed breeding, as males ringed as chicks remain in the group but do not breed in their first two years of life. Further, individuals marked as chicks were often seen to help at the nests of their male or female parent. Future

The genus Icterus *includes species which weave some of the most elaborate of all avian nests, with the exception of the weavers (Ploceidae) of Asia and Africa. The nests of the **Altamira Oriole** and of some other large orioles are tightly woven, elongated pouches, closely resembling the nests of caciques and oropendolas. Between the two extremes are smaller tropical and subtropical species such as the Black-vented Oriole* (Icterus wagleri)*, which builds a shallow, hammock-shaped nest, slung from a branch or stitched to the underside of a palm or banana leaf.*

[*Icterus gularis mentalis*, Bentsen State Park, Texas, USA. Photo: Rob Curtis/ The Early Birder]

*While the female **Red-rumped Cacique** builds the nest, the male perches near her, displaying and singing. Dominant male Red-rumped Caciques are successively polygynous, and the pair-bond ends with the start of incubation. The female of the nominate race takes 5–11 days to build the pensile nest, which is 34–45 cm long, whereas that of the race* affinis *(shown here) is up to 65 cm long and the work takes an average of 18 days. Nest-weaving is a complex process, starting with the firm attachment to a branch or leaf, and continuing with the selection of suitable materials and the intricate movements required to interlace them into a fabric.*

[*Cacicus haemorrhous affinis*, Iguazú National Park, Misiones, Argentina. Photo: José Calo]

studies of co-operatively breeding icterids may reveal the characteristic variability of this family in patterns of social structure and in the parental and extra-parental roles of both sexes.

Movements

Most members of this family are resident, but some undertake migrations of one kind or another. The champion of icterid migrations is the Bobolink. Every year, populations of this species travel thousands of kilometres from breeding grounds in northern North America southwards to non-breeding quarters in central South America; just a few winter in Florida, in the south-east USA. During the course of a year, the Bobolink's northernmost locality is around 52° N in Saskatchewan, in Canada, and its southernmost is at 36°18' S at Punta Rasa, in north-east Buenos Aires, in Argentina. The southbound migratory flocks move mostly through Cuba, the Bahamas and Jamaica. Most Bobolinks

*Using grass stems and other fine vegetable fibres, the **Altamira Oriole** weaves an elongated pensile nest 35–65 cm long, the biggest nest of any oriole species. The nest of this resident of the tropics takes up to 26 days to build, in contrast to the smaller pouch built by the migratory, temperate-breeding Baltimore Oriole* (Icterus galbula), *which takes 5–6 days. The adult Altamira Orioles land at the top of the nest, where the entrance is, and must then crawl head downwards to reach the bottom. It has been suggested that the extreme length of the nest is a defence against predators and brood parasites.*

[*Icterus gularis mentalis*, Bentsen State Park, Texas, USA. Photo: Andy & Gill Swash/ WorldWildlifeImages.com]

*DNA analysis shows that the **Solitary Cacique** is related to the* Psarocolius *oropendolas, rather than to the* Cacicus *caciques. Unlike the polygynous oropendolas, however, the Solitary Cacique is monogamous, and family-members may remain together as a group for some months after the young have fledged. The partners defend the territory and the nest together. In territorial conflicts between pairs, all the individuals may vocalize for 30 minutes or more. The female alone builds the nest, a purse-shaped structure open at the top and wider at the bottom, which can be up to 120 cm long. Old nests in the same tree may indicate that good sites, including those over water, are reused.*

[*Procacicus solitarius*, Pre-Delta National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

cross the Caribbean from Jamaica to the Colombian or Venezuelan coasts, a distance of about 700 km, making this the largest sea crossing regularly taken by any icterid. This species' migration is mostly nocturnal, and the night-flying birds keep contact with one another by means of repeated calls. Occasional stragglers have been recorded in the Galapagos Islands and in western Europe, the latter mainly in September–October in Britain and Ireland.

In tandem with their seasonal shift in latitude, from northern temperate regions to warm temperate and subtropical climates Bobolinks correspondingly change their preferred habitat from wet meadows, when nesting, to marshes, savannas, rice fields and flooded grasslands. In 1906, the naturalist S. Venturi reported migrating flocks containing more than 5000 individuals spread over 3 hectares of marsh in the Argentinian Chaco. Nowadays, Bobolinks are less abundant, although flocks of several thousand are still reported.

Another migratory icterid with non-overlapping breeding and wintering ranges is the Rusty Blackbird. This blackbird breeds mostly in Alaska and Canada, and spends the winter months mostly in the eastern USA from New England and the Great Lakes south to Florida and the Gulf Coast. A few individuals reach northern Mexico. It is one of the few icterids reported outside the Americas, with stragglers observed in Greenland and the Russian Far East. Migrating Rusty Blackbirds have landed on ships 200–400 km off the New England coast. This species, unlike the Bobolink, migrates by day. The Rusty Blackbird's sole congener, Brewer's Blackbird, is migratory in the northern and eastern parts of its breeding range, from where it moves southward to as far as central Mexico.

North American orioles of deciduous woodland, namely the Baltimore, Bullocks's and Orchard Orioles, are highly migratory, vacating their breeding ranges entirely, or almost so, after nesting. Recent research has shown that some Hooded Orioles (*Icterus cucullatus*) and Orchard Orioles that breed in temperate North America apparently move to subtropical west Mexico and breed for a second time, before migrating farther south. Baltimore and Orchard Orioles migrate mostly to Middle America south of Tehuantepec, but a not insignificant number regularly reach northern Colombia and north-west Venezuela. A few Baltimore Orioles winter in southern California, on the south-east coast of the USA, and in the Bahamas and the Greater Antilles, and the species has straggled north to Greenland and east to the British Isles, Norway and the Netherlands. Bullock's Oriole winters mostly in the area from central Mexico south to central Guatemala, a few individuals reaching the Pacific coast of Costa Rica. There are several records of this species from Alaska.

Yellow-headed Blackbirds undertake considerable migratory movements, withdrawing from most of their breeding range in central-west North America. The winter quarters extend from central California and Louisiana, in the USA, south to most of Mexico, rarely to Costa Rica and Panama, and exceptionally to the Bahamas and Cuba. Stragglers have been seen in Greenland. This icterid migrates by day, and males winter farther north than females.

Migration patterns of the Red-winged Blackbird have been studied through extensive ringing efforts. Maps by R. A. Dolbeer showing the movements of single individuals during the period 1924–1979 revealed not only north–south movements but also some east–west ones. The average distances covered were 600–1000 km, and females travelled 200–300 km farther than males. The blackbirds also shifted their successive wintering grounds in the southern USA by 50–150 km. If these shifts alter the return rates to the breeding grounds, then migration has an effect of mixing populations and lowering their genetic differences. Among the eastern populations of the USA and Canada, genetic differences are, in fact, rather small.

A well-known species with a similar distribution to that of the Red-winged Blackbird is the Brown-headed Cowbird. Northern and interior populations of the latter migrate southwards after the breeding season, some reaching as far south as southern Mexico. Individuals ringed in the north-east USA have been recovered up to 850 km to the south. This species has occurred as an accidental on many Caribbean islands, in Belize and, exceptionally, in several countries in western Europe, including Scotland, England, Wales and Norway. Like several other icterids, such as the Western Meadowlark, it also makes altitudinal movements in the Sierra Nevada and the Rocky Mountains of the western USA.

Northern populations of the Eastern and Western Meadowlarks are migratory, whereas their more southerly representatives are resident. Eastern Meadowlarks generally move only short distances, while some Western Meadowlarks may migrate longer distances, extending well south into central Mexico. The true status of the two species in Mexico, however, is somewhat uncertain, as the sight identification of wintering meadowlarks may not be reliable. Otherwise, the Western Meadowlark is a vagrant in Alaska, and has been recorded in Chukotka, in the Russian Far East. It also performs altitudinal movements in the highlands.

The scale of migration by icterids breeding within South America is modest, and involves only a few species in southern Chile and Argentina. Although there is only limited information from bird-ringing programmes, none of these species exhibits a seasonal withdrawal from most of its breeding range, suggesting that migration in these cases is partial. As a good example, the Yellow-winged Blackbird in Argentina is only a summer visitor from southern Mendoza south to Santa Cruz, and only a winter visitor in Paraguay and adjacent provinces of Argentina. In central Buenos Aires Province, Shiny Cowbirds disappear for a few

*The **Baltimore Oriole** is a solitary nester, with its nearest neighbour no closer than 45–60 m. The defended territory is a relatively small area around the nesting tree, and the foraging areas of neighbouring pairs commonly overlap. Yearling males and paired adult males may intrude into the territory in search of extra-pair copulations. The female flees from these attempts, giving loud calls, but may be driven to the ground and mounted. During her fertilizable period, her mate accompanies her constantly when she leaves the territory to forage or to gather nesting material, and chases her back if she strays too close to a neighbouring male. The nest, built mostly by the female, is woven from plant fibres such as grass and stems, although, in cities and gardens, artificial materials such as string and plastic may be used. It is lined with soft materials such as seed plumes or feathers. Adding a lining of this sort is often the only work done by troupials, which take over the nests of other birds. The **Orange-backed Troupial** frequently uses the nests of oropendolas or caciques, or, as here, of thornbirds* (Phacellodomus). *This Greater Thornbird* (Phacellodomus ruber) *nest was taken over by the Orange-backed Troupials but subsequently reoccupied by the thornbirds. Similarly, in the* llanos *of Venezuela, the Venezuelan Troupial* (Icterus icterus) *uses Rufous-fronted Thornbird* (P. rufifrons) *nests, which are multi-chambered, and the troupial may eventually co-exist with other birds, including the thornbirds, using the same structure. But Venezuelan Troupials sometimes destroy the eggs and small chicks of the occupiers, even of other troupial pairs.*

Below: *Icterus croconotus strictifrons*, Mato Grosso, Brazil. Photo: Anita Studer]

*In two species of marsh-nesting blackbirds in South America, namely the **Chestnut-capped Blackbird** and the Yellow-hooded Blackbird* (Chrysomus icterocephalus), *the nests are built by the male. Each male builds a number of nests within his territory, using wet plant material such as grass and sedge that dries to a solid structure. If the female accepts the nest, she lines it with fine fibres. Although some males are monogamous, the mating system of these species is mainly sequential or harem polygyny, with 2–5 females in a harem. The male may remain with the female until incubation begins, but spends most of his time in singing and displaying.*

weeks in late February and March, at the end of the austral summer, but large flocks return by April and remain throughout the winter period. The pattern suggests the replacement of one population by another population, both of them migratory. A Shiny Cowbird ringed in winter in Córdoba Province was recovered 500 km to the south in spring, giving additional support to this idea.

In central Argentina, White-browed Blackbirds form wandering flocks that may shift northwards, but throughout the austral winter roosts of this species can be found in areas of bunch-grass in central Buenos Aires Province. Long-tailed Meadowlarks, which breed in the southern half of South America, occur in the austral winter as far south as the Falkland Islands and Tierra del Fuego, indicating that movements by this species are mostly local. The same pattern probably applies to the Pampas Meadowlark.

Partial migration in response to regular dry seasons is typical of the Scarlet-headed Blackbird, a very specialized marsh-dwelling icterid that finds its food mostly by gaping into the stems of green marsh plants (see Food and Feeding). Regular movements by this species are evident in the Chaco region. During the dry season, the austral winter, only a few remain in the best spots of the dusty and desiccated wetlands of the western Chaco. It is very likely that this and other marsh icterids make irregular movements in response to unusual and severe droughts. During a severe La Niña episode in the autumn of 1997, and again in the dry spring of 2008, just a few Scarlet-headed Blackbirds remained in one of the species' strongholds, the Paraná River delta, in Argentina. During that period, most of the vegetation in the delta remained parched and dry. Conversely, during wet El Niño episodes, icterids breeding in marshes or wet meadows may occur outside their regular ranges.

Nomadism as a general term for "irregular movements" has been applied to temperate-zone icterids, both in North America and in South America. A classic example of nomadism involves bird species that follow swarms of travelling locusts (Acrididae), breeding in the spots of highest insect abundance. There is some historical evidence connecting breeding colonies of Tricolored Blackbirds with locust swarms in the Central Valley of California. Nowadays locust swarms are controlled with pesticides, and this biological phenomenon has consequently disappeared.

Relationship with Man

Knowledge of icterids possessed by several native American ethnic groups is reflected in their systems of bird classification. Perhaps the most elaborate and best-known system is the one still used by many tribes of the widespread Tupí–Guaraní linguistic stock in South America. Tupí-speakers in the lower Amazon Valley include all their familiar icterids, from meadowlarks to oropendolas, in one group, the *Yapúpewar*. The widespread Crested Oropendola, known as the *Yapú* or *Japú*, is regarded as the characteristic bird, or the "chief", of this group. Tupí classification differs markedly, however, from the scientific one in including the Neotropical jays among the icterids. The Guaraní of Paraguay and nearby countries seemingly had a similar classification of icterids, one that influenced the natural-history accounts written by the Jesuit missionaries who lived among them. Father Sánchez Labrador, for instance, mixes up jays, or *acaé*, with oropendolas, or *yapú*, in the bird accounts in his 1767 book *Paraguay Natural*. Even the Spanish colonial naturalist Azara, in his important 1802–1805 book on birds, regarded icterids and jays as close relatives.

The generic name *Cacicus*, coined by B. G. de Lacépède in 1799, derives from the widespread Arawak linguistic family, and has the meaning of "chief". Among Tupí-speaking folk around Manaus, in Brazil, the Yellow-rumped Cacique is sometimes known as the *tuchauá*, the word for "chief". Tupí–Guaraní languages have provided many common names of icterids used in Brazilian Portuguese, such as *Japú*, *Japim*, *Chopim* and *Graúna*, and in the Spanish spoken in Paraguay, parts of Bolivia and north-eastern Argentina, such as *Yapú*, *Chopí* and *Guyrá-hu*. The term *guyrá-hu* means simply "blackbird". In Paraguay, there is a complete Guaraní nomenclature for all the local icterids. Although several Tupí–Guaraní bird names have been borrowed by English speakers, examples being *jacana*, *tucan*, *arasari* and *cotinga*, this has not, unfortunately, been the case with icterids.

Icterid names in other Amerindian languages include *zanate* (in Nahuatl), *loica* (in Mapuche), *paucar* (in Quechua) and *uchi* (in Aymara), applied to grackles, meadowlarks and oropendolas. The term *loica* is used in Chilean and Argentinian Spanish for the meadowlarks, and has entered the scientific nomenclature. The name *trupial*, sometimes spelt as *turpial*, is of unknown

*The trees chosen for **Montezuma Oropendola** colonies are often isolated and usually not part of unbroken forest. They sometimes contain hornet (Vespidae) nests, which may provide defence against predators and cowbirds* (Molothrus). *The nests are suspended from the ends of branches, 13–33 m above the ground. Colonies had an average of 57·5 nests in Mexico (Quintana Roo) and 31 in Costa Rica, with a recorded maximum of 172 nests. The top-ranking male remains in the colony for 52–68% of the time, and lower-ranking males visit during his absences. Of 21 chicks, a third were found to have been sired by the alpha male, 19% by beta males, and the rest by lower-ranking males and others displaying away from the colony.*

etymology, but an onomatopoeic origin, after the song of the Venezuelan Troupial, has been suggested.

Icterids have been exploited by humans for their plumage. The elongated tail of male grackles, including the extinct Slender-billed Grackle, provided the Aztecs with glossy black feathers. Orioles and their feathers have been utilized as ornaments by some native American groups, and dried specimens of Orange-backed Troupials were used as ear ornaments by the Ayoreo in the northern Chaco. The showy yellow tail feathers of oropendolas were widely used in necklaces and head-dresses by tribes living in tropical and subtropical forests. Anthropologists and missionaries were not always well informed about birds and feathers, and many native cultures are now extinct. Nevertheless, reliable examples of the use of oropendola tail feathers for ornamentation are available for a minimum of 20 Amerindian nations, ranging from Colombia (Tukano) and Venezuela (Yanomami) south to Bolivia (Yuracaré), central Brazil (Bororo) and Paraguay (Mbya Guaraní). Most sources mention that the feathers were obtained from the widespread Crested Oropendola, but tribes in the Rio Xingu region also used those of the rarer Amazonian Oropendola.

*Whatever the mating system, and even among monogamous icterids with strong pair-bonds, incubation is exclusively by the female. For the majority of species, including the **Hooded Oriole**, the incubation period is 12–14 days, although it can be up to 20 days for large oropendolas. The Hooded Oriole's clutch is of 3–5 eggs. Male Baltimore* (Icterus galbula) *and Orchard Orioles* (I. spurius) *feed the incubating female, and Baltimore Oriole males may feed her also while she is brooding nestlings.*

[*Icterus cucullatus*, Mexico. Photo: Georgita Ruiz]

The restricted-range ***Forbes's Blackbird****, which is listed as Endangered, is a co-operative breeder. During nest-building several birds may bring material, and a number of adults may feed the chicks. Helpers at the nest have been reported also during incubation. Some icterids which breed co-operatively delay breeding until the second year, and individuals marked as chicks have been seen to help at the nests of their parents. Co-operative breeding has been reported so far for 16 species in nine genera of South American quiscalines, and may occur in some cacique* (Cacicus) *species, too, but no North American quiscalines are known to breed co-operatively.*

[*Curaeus forbesi*, Alagoas, Brazil. Photo: Anita Studer]

Native Americans often plucked feathers from pet parrots, but the existence of domesticated oropendolas is not mentioned. Taking into account the numbers of tail feathers included in some head-dresses, many hundreds of oropendolas were hunted in order to produce ornaments.

Icterids were minor food items for native Americans. There are some archaeological and ethnological data suggesting that the Maya people of Cozumel Island, off the north-east end of the Yucatán Peninsula, ate *Quiscalus* grackles and even Giant Cowbirds. Rural folk in Venezuela still eat Crested and Russet-backed Oropendolas, and retain a belief that the bones of these birds are a good preventative or remedy for respiratory problems. In the southern states of the USA, Bobolinks, Red-winged Blackbirds, Common Grackles and other gregarious blackbirds were widely hunted for food during the nineteenth century. Creole gourmets especially appreciated the overwintering blackbirds that had fattened themselves in the rice fields. Bobolinks have also been hunted for food in Jamaica, where they occur on migration.

The ***Long-tailed Meadowlark*** *is probably monogamous, and both parents feed the chicks. The male (with red in the supercilium) is shown here. Among other species of meadowlark, including the sometimes polygynous Eastern* (Sturnella magna) *and Western Meadowlarks* (S. neglecta)*, the male's contribution is variable, and chick-feeding may be done mainly or exclusively by the female. Long-tailed Meadowlark clutches are of 3–4 eggs, and Eastern and Western Meadowlarks can lay up to seven eggs. The nestling period is 10–12 days, and the young meadowlarks are fed for a further two weeks after fledging.*

[*Sturnella loyca falklandica*, Saunders Island, Falkland Islands. Photo: Ketil Knudsen]

Either because of the colourful plumage or because of their song, many icterids are popular as cagebirds, particularly in Latin America and the Caribbean. Orioles combine pleasant voices and bright colours, and several are commonly encountered in the pet trade. As a consequence of trapping, the Yellow-tailed Oriole is now scarce in many areas of Costa Rica. On the other hand, the Venezuelan Troupial has been introduced on, or escaped to, many Caribbean islands, including Puerto Rico. South American icterids captured as cagebirds because of their plumage include the Scarlet-headed and Saffron-cowled Blackbirds, eminently maladapted for living in captivity; moreover, the latter species is globally threatened. The Chopi Blackbird is highly valued for its song, and some of its populations have been overexploited; bird-trappers often destroy its nests in order to obtain chicks. Even male Shiny Cowbirds have been captured for the pet trade in South America. It is possible that escaped Shiny Cowbirds colonized Chile and some Caribbean islands; if true, this is a most deleterious consequence of the pet trade.

Many Amerindian peoples had myths or folk tales related to icterids. The Selknam people of Tierra del Fuego, for instance, had stories about the two icterids found on their island. The Austral Blackbird has the role of a messenger in one story. In another tale, the Long-tailed Meadowlark had a vicious fight with the Rufous-collared Sparrow and its breast became stained with blood. Meadowlarks play a role in several folk tales of North American Indians, often interacting with the coyote (*Canis latrans*), widely regarded as a "trickster" or mischievous cultural hero. In a somewhat ecologically based legend from central California, Western Meadowlarks advise Coyote not to resurrect the first humans who died, arguing that otherwise there would not be enough resources for the newborn. Coyote accepts the advice, and in some versions he also applies the rule to the meadowlarks.

The Aztecs sacrificed grackles, including the extinct Slender-billed Grackle, to their fire god. The yellow *yuyum* birds—orioles of the genus *Icterus*—are mentioned in prophetic Maya texts as inhabitants of the sacred *yaxché* trees (*Ceiba pentandra*). According to some Amazonian tribes, the oropendolas stole the fire for humans, and as a result the black beak of these birds had a red tip; only species in the subgenus *Gymnostinops* (see Systematics) had this trait. The Tupí name *yapú* or *japú*, applied to *Psarocolius* oropendolas, has the appropriate alternative meaning of "loquacious" or "talkative", and in Guaraní it also means "a liar". The diminutive form *japim* is widely used in Brazil for the Yellow-rumped Cacique, an outstanding mimic. The Victorian traveller and naturalist H. W. Bates mentioned that, in north-eastern Brazil, a popular newspaper in Pará was named *O Japim*, probably because of its tendency to print gossip. In Amazonian folk medicine, eggs of Yellow-rumped Caciques, eaten at midnight, are said to make children talkative.

This cacique is the subject of many folk stories in Amazonia. One tale tells how the arrogant cacique was punished by the gods, forgot his own song, and now copies other animals. In another tale, Yellow-rumped Caciques mock any other bird except red-billed nunbirds, either the Black-fronted (*Monasa nigrifrons*) or the White-fronted Nunbird (*Monasa morphoeus*). The nunbird's red bill, apparently stained with blood, scares the mocking caciques. In a second version, the caciques had once mimicked the nunbirds, until the offended birds used their bill to kill the cacique's parents and grandparents. Another story relates that the caciques, because of their mocking habits, were detested by all other birds, which constantly attacked their nesting colonies. The clever caciques, however, made a pact with the wasps, and the stinging insects now protect their nests. The same biological fact, the nesting association with aggressive wasps, makes the Yellow-rumped Caciques the mythical patrons of the passage rites to manhood endured by the young Wayaná, a Carib tribe from Brazil; during the rites, the candidates are exposed to the "bites" of stinging wasps and ants.

The scientific names of two icterids commemorate Aztec emperors. The Montezuma Oropendola was named *Psarocolius montezuma* after the weak and ill-fated Moctezuma II (often spelt Montezuma), who reigned during 1502–1520. This ruler kept large aviaries at his royal residences, and he may have known this oropendola, as its distribution extended to regions controlled by the Aztec empire in Veracruz. The specific name of the Black Oropendola, *Psarocolius guatimozinus*, honours the brave last emperor Cuauhtémoc, executed by the Spanish conqueror Hernán Cortés in 1525. This icterid, however, occurs in areas far south of those under former Aztec control. The great French naturalist d'Orbigny dedicated the scientific name of the Amazonian Oropendola to the Yuracaré, the proud Indian people who lived in the foothill forests of Cochabamba, in Bolivia.

Spanish or Portuguese names applied to icterids often have a "military" connection, as illustrated by *dragón*, meaning "dra-

*In studies of **Bullock's Oriole** in San Angelo, in Texas, the eggs hatched asynchronously over 2–4 days. The hatchlings grew at the rate of 3 g per day. The chicks of this oriole are fed by both parents, and the nestling period is 14 days. In Washington and California, fledglings may join crèches of up to 100 individuals, attended by several adults. After breeding, Bullock's Orioles move south-west to moult, before completing their journey to Mexico.*

[*Icterus bullockii bullockii*, Milpitas, California, USA. Photo: Alex Navarro]

A brood of three ***Orange-backed Troupial*** *chicks was reported from Argentina, but there is no other information on parental care or the nestling period of this species. For the Venezuelan Troupial* (Icterus icterus), *formerly considered conspecific with the Orange-backed, the published nestling period is 21–23 days, substantially longer than for any other* Icterus *species for which information is available, and almost twice as long as for temperate-breeding orioles. Both Venezuelan Troupial parents feed the young and defend the nest. Orange-backed Troupials usurp the nests of other species; this is the nest of a cacique or oropendola.*

[*Icterus croconotus strictifrons*, Mato Grosso, Brazil. Photo: Anita Studer]

goon", given to species of *Pseudoleistes* and *Xanthopsar* in Argentina and Uruguay, and *policia inglesa*, "English policeman", applied to *Sturnella* species in Brazil. The species name *militaris*, used for the Red-breasted Blackbird, is part of this same tendency. The Mexican name of the Red-winged Blackbird, *Tordo Sargento*, or "Sergeant Blackbird", derives from the species' coloured epaulets. Similarly, the Argentinian name *federal*, applied to the Scarlet-headed Blackbird, is related to this icterid's vivid red colour, used by the federal militias during the civil wars of the early nineteenth century. The Chestnut-capped Blackbird is known in southern Brazil as *garibaldi*, after the Italian independence hero Giuseppe Garibaldi, who was previously a guerrilla leader against the Brazilian Empire in the 1830s. Many vernacular Spanish American names are of direct Iberian origin and were previously used in Spain for entirely different birds; examples are *tordo*, *mirlo*, *oropéndola* and *arrendajo*, which referred to, respectively, thrushes, blackbirds, orioles and jays.

Both ***Brewer's Blackbird*** *parents feed the chicks, though a minority of polygynous males may divide their time between broods. The shiny black male is shown here. Similarly, the male may feed the female while she is incubating, although the polygynous male will desert the primary female once incubation has begun. In California, the number of polygynous males varies from year to year, depending on sex ratios within a colony. Males have a maximum of three mates, which may be scattered within the colony. Territorial defence is limited to a small area around each nest-site. Food for the chicks is obtained up to 800 m from the colony.*

[*Euphagus cyanocephalus*, British Columbia, Canada. Photo: S. Roberts/ Ardea.com]

*Aggressive nest-guarding by the **Scarlet-headed Blackbird** seems to keep the incidence of cowbird parasitism lower than in other marsh-nesting icterids. The average brood is three, although the last to hatch often fails to survive. The nest is attached to 4–7 stems of reeds or other tall aquatic vegetation, around 1 m above the water. Both sexes feed the young. Although the very distinctive plumage is common to both sexes, the female may occasionally breed in juvenile plumage, which lacks red altogether and is yellowish on the throat and breast.*

[*Amblyramphus holosericeus*, Mato Grosso, Brazil. Photo: Anita Studer]

Vernacular Caribbean English names applied to icterids also include "military" themes, such as "Wild Pine Sergeant" in Jamaica for the Jamaican Blackbird and "Soldier Bird" in Trinidad for the Red-breasted Blackbird. Some humorous Jamaican names for icterids include "banana bird" or "auntie katie" for the local oriole. North American English names are not of Amerindian origin, and are simply descriptive, such as "cowbird"; of European origin, "meadowlark" and "oriole"; or both, "blackbird"; with the occasional onomatopoeic name, for instance "Bobolink". Much the same applies to French Canadian names. The most characteristic French name for icterids is *carrouge*, applied mostly to orioles.

Nesting associations with humans are well developed in a few Neotropical icterids. In Paraguay and north-eastern Argentina Chopi Blackbirds often nest in buildings, a habit reported by Azara over two centuries ago. One of the most unusual breeding locations for a medium-sized group of Chopi Blackbirds was the international airport at Iguazú Falls, in Argentina, where the birds even nested in the noisy terminal building. In the same region, colonies of Red-rumped Caciques are usually sited around human dwellings and similar places, including hotels, restaurants, parking lots and police headquarters. If the buildings are abandoned, the caciques desert the colonies. Humans and domestic dogs probably deter many nest predators, from snakes to monkeys, and in Argentina some people in Misiones even purposefully help the nesting caciques by clapping the hands or yelling to scare off visiting toucans (Ramphastidae). The Yellow-rumped Cacique sometimes nests near human habitations in Venezuela, Trinidad and Bolivia. According to the naturalist W. H. Beebe, Venezuelan Indians never disturbed the nesting colonies located in their villages.

A rather different picture emerges in present-day North America, where blackbirds are regarded as unwelcome neighbours. Icterids such as *Agelaius* blackbirds, cowbirds and grackles may form night roosts of millions of birds, often in the company of Common Starlings (*Sturnus vulgaris*). A US government survey in the winter of 1974–1975 revealed 723 major roosts containing 438 million icterids, along with 99 million starlings. Red-winged Blackbirds, Common Grackles and Brown-headed Cowbirds, in that order, were the commonest icterids. Such huge concentrations can represent a major environmental problem, particularly in urban and suburban areas. Blackbird roosts are a problem also in agricultural areas. Attempts to control the numbers have included the spraying of roosts with chemicals toxic to birds or with plant defoliants, and even the use of explosives. Unfortunately, relatively rare and harmless icterids, such as wintering Rusty Blackbirds, which may share roosts with the troublesome species, also fall victim to such control measures.

Urban roosts of Great-tailed Grackles are an increasing nuisance in Central America. In Costa Rica, for example, the authorities in some towns in Guanacaste Province have cut down

*Male orioles and other icterids may become more assiduous providers of food for their young as they grow older. The male **Baltimore Oriole** take two years to attain his adult plumage. First-year males, with plumage intermediate between second-year males and females, do sometimes breed, but have smaller clutches and lower fledging rates than older males. A study of Audubon's Oriole* (Icterus graduacauda) *found no difference in the number of feeding trips, 2–3 per hour, made by the male and female parents. A female without a mate made double the number of feeding visits (five per hour) to compensate for the lack of assistance.*

[*Icterus galbula*, Ithaca, New York, USA. Photo: Marie Read]

*The **Brown-headed Cowbird** is an extreme generalist, known to parasitize over 200 species, mostly passerines in the size range 10–150 g. Important hosts include vireos (Vireonidae), here a Red-eyed Vireo* (Vireo olivaceus)*, tyrant-flycatchers (Tyrannidae), New World warblers (Parulidae), American sparrows (Emberizidae), and other icterids. Female Brown-headed Cowbirds reportedly produce up to 40 eggs per season. They regularly puncture host eggs or remove them from the nest. Cowbird eggs have shorter incubation times than those of hosts, so that they hatch first and the chicks outcompete surviving host nestlings.*

[*Molothrus ater ater*, Indiana, USA. Photo: Ron Austing/VIREO]

trees in order to expel the grackles. In central Argentina, wintering Shiny Cowbirds sometimes form roosts of several thousand individuals in rural towns, where the sites chosen may be street trees or even plazas and gardens. So far, this habit has caused only minor problems.

Frugivorous icterids, such as oropendolas, will at times feed on cultivated fruits, including oranges, bananas, cacao pods and similar produce. On these grounds, the Crested Oropendola has sometimes been classed as an agricultural pest, for example in Trinidad, and the same applies to certain other species. With their limited numbers, however, oropendolas are unlikely to be important crop pests except, perhaps, on a very local scale.

On the other hand, granivorous icterids that form huge flocks can become serious pests of cereal and sunflower (*Helianthus*) crops. Red-winged Blackbirds will attack ripening maize (*Zea mays*), using a gaping bill action (see Food and Feeding) to obtain the seeds. The damage can be locally important in several areas of North America. Nevertheless, the overall damage in the state of Ohio is just about 1% of the total maize harvest. Red-winged Blackbirds prefer to visit agricultural fields within 8 km of their roosts, and it is therefore the farms in such locations that suffer most of the crop losses. Roost size and roost location are the critical factors. Damage can be minimized by planting near the roosts alternative crops, such as soybeans or potatoes, which are not used by the blackbirds. Recently, varieties of maize and sunflower that are morphologically resistant to blackbird damage have been developed.

A particularly troublesome icterid in South America is the Chestnut-capped Blackbird, regarded as a pest in rice fields throughout the Río de la Plata Basin in Brazil, Paraguay, Uruguay and Argentina. Some sources claim that the annual damage that this species inflicts on rice in Rio Grande do Sul, in southeast Brazil, amounts to about US$100,000,000, but this may be an exaggeration. Analysis of the contents of hundreds of stomachs of the blackbird shows that rice accounts for 12–62% of the items consumed, the proportion varying with season. It appears that the main damage occurs during sowing. Sometimes the blackbirds have been poisoned with highly toxic baits, leading to huge mortality of other birds, too. Despite decades of persecution, Chestnut-capped Blackbird populations have not been reduced, and perhaps a more environmentally friendly method of control should be devised. In addition, studies in Argentina suggest that the damage done to rice is exaggerated, and partly compensated by the species' consumption of insects harmful to the crop. Like the blackbird, the Bobolink is commonly regarded as a pest in rice fields in Bolivia and Argentina. Other South American icterids sometimes considered to be agricultural pests, mostly attacking maize, include the Shiny Cowbird and the Chopi and Bolivian Blackbirds, but none of these has been much studied.

Since the 1950s, the members of this family have been of capital importance in the development of biological disciplines studying the social behaviour and organization of animals. This is particularly true of North American species such as the Red-winged, Yellow-headed and Tricolored Blackbirds. Their conspicuousness, abundance and colonial nesting habits have made these species the favourites of students of ecology and animal behaviour. Early studies of comparative social organization in the 1960s used icterids as models. Field research on marsh blackbirds by Orians and his students produced the first hypothesis on the evolution of polygamy in animals. Data showing a discrepancy between the visible pair-bond and actual promiscuous copulation behaviour were first obtained for female Red-winged Blackbirds. This icterid is certainly one of the best-studied bird species in the New World. Neotropical species have been less researched, but some types of social organization, such as cooperative breeding, are known mostly in respect of South American taxa. Brood parasites such as the cowbirds have for long fascinated many biologists and naturalists. Every year, numerous studies are published on various facets of the parasites' life histories, ranging from egg mimicry to the problems of learning and imprinting.

Literary works relating to icterids are not many. The poem entitled "Robert of Lincoln", by the nineteenth-century author William Cullen Bryant, describes the life of the Bobolink with affection and irony. Grackles were the subject of a humorous poem by another renowned North American, Ogden Nash:

> The grackle's voice is less than mellow,
> His heart is black, his eye is yellow,
> He bullies more attractive birds
> With hoodlum deeds and vulgar words,
> And should a human interfere,

*This **Golden-winged Cacique** is removing and carrying away a faecal sac from its nest. Conspicuous objects such as faeces and eggshells could attract predators or brood parasites if dropped directly below the nest, and tend therefore to be disposed of at a distance. The faeces of very young chicks may be swallowed: this has been observed for Audubon's Orioles* (Icterus graduacauda) *with two-day-old nestlings. Golden-winged Caciques are frequently parasitized by the Shiny Cowbird* (Molothrus bonariensis). *This cacique is an "accepter" species, which raises the cowbird chicks instead of, or as well as, its own. Some icterids are "rejecters": they recognize the eggs as alien and carry them away from the nest. When cowbird eggs were experimentally placed in 16 Baltimore Oriole* (I. galbula) *nests, all were rejected, 14 of them within one hour. Females ejected the cowbird egg at eleven nests, males at two nests, and at one nest both sexes participated in egg removal. At eight nests the eggs were spiked with the open beak and carried away, and at six nests the eggs were broken and removed piece by piece. Except for one egg that was dropped immediately beneath the nest, the orioles carried the eggs 1·5–35 m away. It has been suggested that egg ejection resembles nest-sanitation behaviour, such as the removal of faecal sacs, and may have evolved from it.*

[*Cacicus chrysopterus*, Río Pilcomayo National Park, Argentina. Photos: José Calo]

*The males of polygynous oropendolas and caciques, such as this **Red-rumped Cacique**, usually play little or no part in provisioning the young, but actively defend the nest or colony from predators such as toucans (Ramphastidae) and monkeys. Caciques, oropendolas and orioles sometimes nest near aggressive insects, such as wasps (Vespidae) or ants (Formicidae), that deter climbing predators, or share the nest tree with jays (Corvidae) or tyrant-flycatchers (Tyrannidae), which are aggressive towards avian predators. Red-rumped Caciques may nest near humans, and in towns, as an anti-predator strategy.*

Attacks that human in the rear.
I cannot help but deem the grackle
An ornithological debacle.

In the Spanish language, the best examples are perhaps two poems by the Argentinian writer Leopoldo Lugones, a member of the nation's ornithological society and obviously familiar with birds. In his 1917 book *Libro de Paisajes*, "Book of Landscapes", he dedicates a poem to the Solitary Cacique, conjuring up, in a few words, the mood of the bird, its habitat in the Paraná Delta, and its remarkable nest.

Some orioles have been awarded the title of "national bird", examples being the Venezuelan Troupial in Venezuela and the Montserrat Oriole in the island nation of that name. Similarly, the Baltimore Oriole has been named the state bird in the US state of Maryland. Orioles are colourful, have pleasant voices and seldom interfere with human economic interests. These are surely among the primary reasons why orioles have such a positive public image and are greatly appreciated by birdwatchers and others alike.

Status and Conservation

Only one icterid species has become extinct in historical times. This is the Slender-billed Grackle, a medium-sized slender grackle with visible sexual plumage dimorphism. Described in 1827, by W. J. Swainson, this species had a restricted distribution in the marshes of the Valley of Mexico and the Toluca Valley, in the central Mexican highlands; ethnological data gathered by the Spanish missionary Sahagún indicate that the Aztecs were certainly familiar with it (see Relationship with Man). The wetlands were steadily drained during the nineteenth century, and the grackle was last reported in 1910. Almost nothing is known of the ecology and natural history of this icterid; it possibly nested colonially in reedbeds, but it was also reported from towns. Mitochondrial DNA extracted from museum specimens shows that it was not related to the Nicaraguan Grackle, as previously suggested, but to the widespread and abundant Great-tailed Grackle (see Systematics).

Of the 111 extant species in the family, 14, almost 13% of the total, are currently listed as globally threatened. Perhaps not surprisingly, five of the threatened icterids are restricted to islands of the West Indies, where they represent 26% of the resident Caribbean icterids. A further Caribbean species is currently considered Near-threatened. This is the St Lucia Oriole (*Icterus laudabilis*), confined to the island of that name. The remaining nine threatened icterids include seven South American taxa, together with the North American Rusty and Tricolored Blackbirds. Five of the South American species have isolated and small ranges, ecologically approaching an insular situation.

Two of the 14 threatened species are listed as Critically Endangered. The Montserrat Oriole, found only on a single small

*Both the solitary-nesting **Yellow-rumped Marshbird** and the colonial Brown-and-yellow Marshbird* (Pseudoleistes virescens) *are co-operative breeders. Up to six helpers assist both parents with feeding the nestlings and defending the nests against raptors. Helpers may be associated with the nest during incubation, but the number of helpers increases after hatching. Brown-and-yellow Marshbirds almost never leave the nest unattended during the brood-rearing stage. Despite this, both marshbirds are heavily parasitized by cowbirds* (Molothrus) *and the nesting success of the Brown-and-yellow Marshbird can be low.*

[*Pseudoleistes guirahuro*,
Das Emas National Park,
Goiás, Brazil.

island in the northern Lesser Antilles, has declined seriously owing to an unhappy combination of human pressure, natural catastrophes and the small size of its island range. Formerly it was found in all of the main montane forests, but these were reduced by increasing cultivation to a few suitable patches. The Soufrière Hills volcano, after a long period of dormancy, erupted in 1995, damaging or destroying the remaining forest patches; the volcano has remained active ever since then. The number of surviving orioles was estimated to be 5200 individuals in 2004, while a more recent assessment was of a total population of 460–590 pairs. These are more or less confined to the Centre Hills. Research studies, using nest cameras, revealed high rates of nest predation by introduced rats (*Rattus*) and native Pearly-eyed Thrashers (*Margarops fuscatus*), both of which are present at often high densities. In 2001 and 2003, a reduction in the oriole's laying frequency and clutch size was thought to have been caused by drought, and this could become a more serious problem since the species is now confined to lower, drier parts of the island. Similarly, excessively heavy rainfall can have an adverse impact. A significant additional problem is presented by feral livestock, which eat native plants and hinder forest regeneration; they destroy the native *Heliconia caribea*, the oriole's preferred nesting plant. Particularly destructive is the feral pig (*Sus*) population, which is spreading rapidly and could, if left to its own devices, seriously damage the forest habitat. A programme of captive-breeding of Montserrat Orioles was started in 1999 and appears to have achieved some success; to date, this has been regarded as a precautionary measure, in case the species does become extinct in the wild. Several other conservation measures have been taken. The Centre Hills have been designated a protected area, within the marked boundaries of which no development is permitted. A Species Action Plan was published in 2005, and experimental rat control in the Centre Hills began in the following year. There are also plans for a pig-eradication programme on Montserrat.

Following the recent taxonomic split of the "Greater Antillean Oriole" into four distinct species (see Systematics), the status of these taxa had to be individually assessed. As a result, the Bahama Oriole (*Icterus northropi*) has now been listed as Critically Endangered. This icterid was formerly found on Abaco and Andros, in the western part of the Bahamas, but it disappeared from Abaco during the early 1990s, and the Andros population appears to be declining. The reasons for its extirpation from Abaco are not known. Recent surveys covering the whole of Andros indicate that the total population may be as few as 127–254 individuals. Moreover, among the birds recorded during a survey in 1997 was only a single individual in juvenile plumage, indicating an alarmingly low reproductive output; happily, more juveniles have been seen during later surveys. The species inhabits mature coppice woodland, nesting in thatch palms (*Thrinax*) and in non-native coconut palms. Unfortunately, the coconut palm on Andros has been attacked by lethal yellowing, a phytoplasma pathogen that attacks many species of palm, killing the palm within six months. The phytoplasma, thought to be spread by the planthopper *Haplaxius crudus*, first causes the fronds to turn yellow, before the entire crown falls to the ground. The disease has evidently eradicated the coconut palm in parts of North Andros; for example, the oriole is no longer to be found at Staniard Creek, where it was previously common. Lethal yellowing has not yet been detected on Mangrove Cay or South Andros, both of which held very healthy palm populations, and higher oriole densities than North Andros, in 2009. An additional new threat to the Bahama Oriole is brood parasitism by the Shiny Cowbird, which has recently arrived on Andros. In summary, the Bahama Oriole is one of the rarest avian species in the Caribbean region.

Of the remaining twelve globally threatened icterids, seven are listed as Endangered and five are Vulnerable. Among the seven Endangered members of the family, only one, the Tricolored Blackbird, is found in North America. This species occurs mostly in the Central Valley of California. It formerly nested in colonies containing hundreds of thousands of birds, but in the last hundred or so years human activities have dramatically reduced both its habitats and its numbers. It is classed as being considered of "Highest Concern" in the USA (Red WatchList priority species for conservation).

Somewhat mysteriously, the Rusty Blackbird, the northernmost icterid and one having a huge distribution in boreal North America, has suffered a serious long-term population decline that appears to have accelerated since the end of the last century. It qualifies as Vulnerable, although more accurate survey data may indicate that a re-evaluation of its status is warranted. It is classi-

Studies have found that nearly all hosts, despite the often great disparity in size, are able to meet the demands of ***Brown-headed Cowbird*** *chicks. Growth rates of this cowbird's nestlings have been shown to be nearly identical in nests of hosts weighing 9·5 g and 52·6 g, although Brown-headed Cowbirds in nests of House Finches* (Carpodacus mexicanus), *which feed their young with regurgitated seeds, fail to survive. Conversely, when Shiny Cowbird* (Molothrus bonariensis) *chicks were raised by host species varying in weight from 12·8 g to 74 g, their mass at fledging increased with that of the host.*

[*Molothrus ater artemisiae*, Pica County, Arizona, USA. Photo: J. Hoffman/VIREO]

fied as "Declining" in the USA (Yellow WatchList priority species for conservation). This species breeds right across the northern forest zone, and then migrates to non-breeding quarters throughout the eastern USA. Since the 1970s, surveys and counts have revealed annual rates of decline ranging from about 5% to 12%. From historical accounts, it appears that Rusty Blackbird numbers have been falling steadily for more than a century. There are several possible reasons for this decline. Perhaps the most likely is the loss and degradation of wooded wetlands, the habitat on which this species is dependent throughout the year; this has been a particular problem in the non-breeding range. In recent decades, habitat disturbance and environmental contamination, as well as global climate warming, may have had adverse effects on breeding numbers and success. In 2005, a special group, the International Rusty Blackbird Working Group, was set up with the aim of developing research that would enable scientists to understand the true causes of the decline. This research includes, among other aspects, investigation of the species' habitat use on the breeding grounds and in the winter quarters, its breeding success and its moult patterns. Some of the early findings were that methylmercury levels in tissues were higher in the breeding area than in the wintering range, and that, in winter, individuals are vulnerable to parasite and microbial infections, this possibly a result of stress induced by degradation of the wintering habitat. In addition, it seems that the blackbird's habit of nesting in small stunted conifers, mainly spruce (*Picea*), can produce mixed fortunes. When it used such nest-sites in undisturbed wetlands in Alaska and New England, it achieved relatively high success; in contrast, when Rusty Blackbirds in New England nested in young spruces or balsam firs (*Abies balsamea*) that had regenerated after recent logging of wetlands or adjacent uplands, they suffered far greater nest predation, leading to a reduction in nest survival of almost 70%. The researchers suggested that unlogged buffer zones around wetlands should be considered as a conservation measure for the protection of nesting Rusty Blackbirds. The various studies are continuing.

In addition to the Montserrat and Bahama Orioles, three other Caribbean species are threatened. The Jamaican Blackbird and the Yellow-shouldered Blackbird are both considered Endangered and the Martinique Oriole (*Icterus bonana*) is Vulnerable. Jamaican Blackbirds occur mostly in wet montane forest, a habitat threatened by several human activities, including mining, logging and the commercial planting of exotic trees, as well as fires. Removal of mature native trees may have had a particularly serious effect on this species, as these trees support the large bromeliads in which the blackbird forages for insects. A significant population of Jamaican Blackbirds is found in the Blue and John Crow Mountains National Park, which covers an area of more than 800 km² and is part of a system of protected areas with at least 40 forest reserves, in some of which this species occurs. The management of such reserves and the enforcement of regulations tend to be weak, however, and habitat destruction continues within them, so their long-term security is by no means assured. The species' total population is thought to be within the range 2500–10,000 individuals.

The Yellow-shouldered Blackbird has declined in both range and numbers. The nominate race once occurred throughout mainland Puerto Rico, and a second subspecies was widespread on the offshore islands of Mona and Monito. On Puerto Rico, the population was estimated at 2400 individuals in 1975, but, following a drastic contraction of its range, it is now confined mostly to the south-west coastal area; a small remnant population persisted in eastern coastal areas, but this appears to have disappeared, with no breeding records since 1986. In south-west Puerto Rico, the population declined by about 80% between 1975 and 1981, and in 1982 numbered no more than 300 individuals, but roost counts made prior to the breeding season during 1985–1995 revealed an average annual increase of 14%. The global population in early 1998 was estimated at 1250 individuals. This blackbird seems always to have been most numerous in places near the coast, and nowadays many of the surviving population breed on offshore cays. One of the main reasons for this species' decline was brood parasitism by Shiny Cowbirds, which invaded Puerto Rico around the mid-1950s or before, and this has been cited as the chief cause of the shift to offshore cays. Habitat disturbance enabled the cowbirds to increase and spread rapidly. Additional factors include habitat loss through clearance for agriculture, as well as nest predation by Pearly-eyed Thrashers and increased mortality caused by introduced carnivores. A further threat comes from Caribbean Martins (*Progne dominicensis*) invading the blackbird's nesting areas. Among conservation actions taken since 1982 are the installing of artificial nests, the monitoring of breeding results, and control of the numbers of cowbirds, rats and nest mites (Acarina). Cowbird control, as well as habitat management,

The nominate race of the ***Jamaican Oriole*** *(shown here) is still common in Jamaica, and the race* lawrencii *is said to be abundant on the island of San Andrés, off the coast of Nicaragua. But the third race of this restricted-range species,* bairdi, *restricted to Grand Cayman, has not been seen since 1967 and is believed to be extinct. The reasons for its demise are unknown. In Jamaica, the species inhabits most kinds of woodland, from coasts to the mountains, and on Grand Cayman it was found even in town gardens. The race* lawrencii *is brighter in colour than the nominate, and* bairdi *was both smaller and brighter.*

[*Icterus leucopteryx leucopteryx*, Port Antonio, Jamaica. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

Scarce but still widespread in all types of forest, scrub and plantation edges on its home island, the ***St Lucia Oriole*** *has a global range of 620 km². It has been declining since the 1930s, perhaps earlier, owing to a combination of pesticides, habitat loss, parasitism by Shiny Cowbirds* (Molothrus bonariensis) *and increasing numbers of Spectacled Thrushes* (Turdus nudigenis), *which are aggressive towards other thrush-like birds. Though small, at perhaps not many more than 1000 mature individuals, the St Lucia Oriole population appears stable and not at immediate risk. It is considered Near-threatened.*

[*Icterus laudabilis*, St Lucia. Photo: Hank Chiu-wen Seng/AGAMI/ Spectrum photofile]

begun in 1980, led to an improvement in nesting success, and in south-west Puerto Rico, where the Boquerón Commonwealth Forest is a stronghold for the blackbird, its numbers have continued to recover, albeit slowly. So far as is known, cowbird eggs have not yet been found on Mona Island, where the Yellow-shouldered Blackbird population is thought to number about 700 individuals and appears to have remained stable.

Like other Caribbean members of the family, the Martinique Oriole has suffered notably from parasitism by the Shiny Cowbird. Its global range is tiny, being restricted to the island of Martinique, but it is still reasonably numerous, with a population recently estimated at more than 10,000 individuals. It was originally found in many types of forest below 700 m, ranging from semi-arid woodland to forest edge, plantations and rainforest, but there is some evidence that it favours dry forests and mangroves. Since the 1970s this icterid has become less common, its slow decline believed to be due to the invasion of its island by the cowbird. Deforestation on Martinique has allowed the Shiny Cowbird to spread, and it now parasitizes 75% of the oriole's nests each year. On the other hand, a recent decline in the cowbird's numbers has enabled the oriole to recover some of its population losses, albeit on a very small scale. The true impact of the cowbird on the Martinique Oriole, however, is not really known, and the situation should be monitored. In the meantime, further deforestation on the island would almost certainly lead to a range expansion by the cowbird and should be prevented.

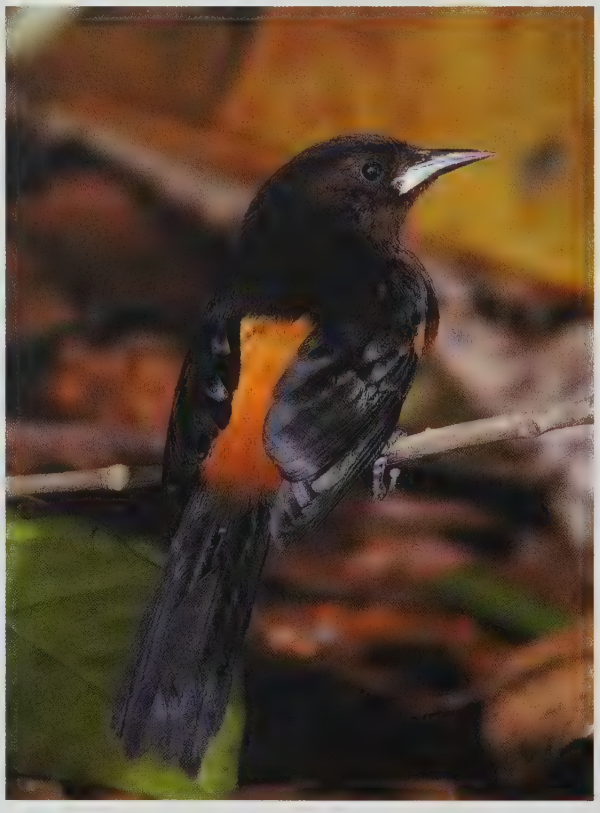
South America harbours the remaining seven globally threatened species. One of these is the enigmatic Selva Cacique, a rare and local icterid that was, until the last few years, known from only three localities within a tiny area of Peru. Recently, however, it has been located in at least one additional protected area. Its known range is fragmented, and it may occur also in Acre, in adjacent west Brazil. Its preferred habitat appears to be riparian vegetation and riverine forest. All records of this species have been made in sparsely populated areas that appear not to be under imminent threat of habitat loss. Its presence in Manu National Park and in the Santuario Nacional Megantoni has now been confirmed, and the species may occur also in Cordillera Azul National Park. The Selva Cacique is currently listed as Vulnerable, but it is possible that, if further populations are discovered in neighbouring areas, its status could be downgraded to Near-threatened.

Three globally threatened species are confined to Colombia. These are the Baudo Oropendola, restricted to the coastal lowlands and foothills of Chocó, in north-west Colombia, and the Colombian Mountain Grackle (*Macroagelaius subalaris*) and Red-bellied Grackle, both found in the Andes of that country. It is possible that the Baudo Oropendola also occurs in nearby areas of Panama. All three are listed as Endangered. The Baudo Oropendola, until very recently known from only five localities and possibly a naturally scarce species, seems to prefer lowland forest growing in sandy deposits and with a relatively open

The ***Selva Cacique*** *was for long known only from the type locality in Loreto, in Peru. Then, in the late 1990s, it was found at two further sites, on the Río Shihuaniro and the upper Río Camisea, in Cuzco. It has been seen in Manu National Park and Biosphere Reserve and in Megantoni National Sanctuary, with an unconfirmed report from Cordillera Azul National Park. It is thought to occur at low densities, and is apparently very local. Its riverine-forest habitats are at risk from agriculture and settlement, but it has been heard calling from mosaics of forest and cultivated land around a village. It is currently considered Vulnerable.*

[*Cacicus koepckeae*, Río Camisea, La Convención, Cuzco, Peru. Photo: Pablo Grilli]

*In the 1800s, the **Saffron-cowled Blackbird** was found in southern Brazil, Paraguay, and over much of north and central Argentina and most of Uruguay. Its range has contracted sharply, leaving a few widely separated populations totalling perhaps no more than 5000 individuals. The greatest threats are from the damming of marshy valleys for irrigation, and high rates of nest loss owing to trampling by cattle; colonies have been destroyed by fires used in grazing management, and in south Paraguay almost 70% of suitable breeding habitat is covered by rice fields. Saffron-cowled Blackbirds are captured illegally for the cagebird trade, which can destroy entire colonies.*



[*Xanthopsar flavus*, São Francisco de Paula, Rio Grande do Sul, Brazil. Photo: Edson Endrigo]

canopy. A breeding colony had been recorded at the headwaters of the River Acandí in 1991, and at a site north of Ensenada de Utría National Park, near the Pacific coast, two individuals were seen in 1997 and six were observed two years later. In 2010, however, during an expedition in the western Andes in Chocó, two colonies of this oropendola were discovered not far from Medellín. These colonies, totalling 70–80 individuals, are about 120 km from Ensenada de Utría National Park, close to the only other site where a very small number of the species were thought to survive. The two newly discovered colonies are not within a protected zone and, most worryingly, deforestation in the area is accelerating. Conservation measures are required as a matter of urgency, and further surveys are being conducted at the site in order to determine the precise actions that are needed. Habitat alteration and destruction, which are increasing in western Colombia, are the most serious threats to this very rare species.

The Colombian Mountain Grackle is found only on the west slope of the east Andes from Norte de Santander south to Cundinamarca. Its preferred habitat appears to be Andean oak (*Quercus humboldtii*) forest, and is therefore greatly fragmented. In recent surveys, this icterid was recorded at 22 localities ranging from Suratá, in Santander, south to La Aguadita, in Cundinamarca, but follow-up surveys revealed that many of these sites were suffering rapid deforestation. In surveys between 2003 and 2006 in the Serranía de los Yariguíes, a spur extending from the main east Andean range in Santander, it was found at three sites, at one of which it was abundant. The species' current total population has been estimated to be in the range 1000–2500 individuals. Formerly, it occurred over a more extensive region, and probably extended also to the east slope. Much of its mountain-forest habitat, however, has been logged or cleared for agriculture. Nevertheless, the Yariguíes massif, a steep, forested mountain range about 100 km in length, still holds a considerable amount of forest at elevations suitable for this icterid. In January 2011, an important new population was discovered in the Yariguíes range at Reserva Páramo La Floresta, a privately owned reserve administered by the municipality of Zapatoca. This site, at an elevation of about 2600 m, includes second growth, sub-*páramo*, fragments of oak forest and, importantly, a *humedal*, or marshy wetland. In the forest and forest edge surrounding this marshland, the Colombian Mountain Grackle was the most conspicuous bird species, and possibly even the most numerous one. Very similar-looking habitats exist in many parts of the Yariguíes range, but, as they are on isolated plateaux of steep forested mountains, they are very difficult to reach. It seems likely that these, too, support significant populations of the species. Elsewhere, this species' population is small and severely fragmented, and it is debatable whether or not it can survive. Conservation efforts and ecological studies at Guanentá–Alto Río Fonce Fauna and Flora Sanctuary, in Santander, and at Soatá and Tipacoque, in Boyacá, appear to have had some success and are continuing.

Third and last of the threatened Colombian icterids is the striking and distinctive Red-bellied Grackle, found in the Andean mountain forests at altitudes of 800–2750 m. It formerly occurred mostly in the western and central Andean ranges, from Antioquia south to Putumayo, but with a disjunct population in the eastern Andes in Huila and Caquetá. Probably as a result of extensive forest clearance, the species disappeared from much of its earlier range, including the western Andes, and from several historical localities elsewhere. Since about 1980, it has been observed in small numbers very locally, but it is said to be quite common in the mountains around Medellín and La Linda, Las Nubes and La Noque, in Antioquia. Captives from Santafé Zoo were released into the mountains around Medellín during 1997–1998. The species' range, however, remains highly fragmented. Nevertheless, this grackle has been reported living at forest edges and in old second growth, and even nesting in an isolated tree in a pasture, suggesting some tolerance of forest clearance and disturbance, and it has been found recently at several new localities, such as Amalfi, in Antioquia. The present known range of the Red-bellied Grackle includes some protected areas, such as Ucumarí Regional Park and Cueva de los Guácharos National Park. Despite these encouraging signs, detailed surveys and a population estimate are much needed. Its remaining habitat is becoming increasingly degraded and fragmented, suggesting that the species is probably undergoing a gradual decline. It is sometimes persecuted as a pest of commercial maize crops, and is sometimes trapped for the cagebird trade.

Forbes's Blackbird is another species with a very small overall population, estimated in the range of 1000–2499 individuals. It is confined to east Brazil, and was probably a rare and localized bird when first discovered, in 1880, in the state of Pernambuco. For a century there were no further records of this

*The **Martinique Oriole** remains common on Martinique, with a population of more than 10,000 birds and a density of 2·4 birds/ha in the centre of the island. Orioles are found in plantations and town gardens, as well as in native forest and mangroves. The species is listed as Vulnerable because of its very small range (1100 km²) and because brood parasitism by the recently established Shiny Cowbird* (Molothrus bonariensis) *has led to a decrease in its numbers. But the cowbirds have declined recently, allowing a slight recovery in the oriole's population.*

[*Icterus bonana*, Arboretum north of Fort de France, Martinique. Photo: Doug Wechsler/ VIREO]

*The **Pampas Meadowlark** was formerly common and widespread in east-central Argentina and Uruguay, but since 1900 its range has decreased by 90%. Nowadays it is found mostly around Sierra de la Ventana, in south-west Buenos Aires, where the rocky soils do not favour ploughing. This population may approach 28,000 individuals, and there is an isolated population of up to 90 pairs in Uruguay. Some birds breed in planted pasture and croplands with a similar structure to that of the natural habitat, but most are confined to natural grasslands. Between 1992 and 1999, 30% of these grasslands were converted to farming. The Pampas Meadowlark is currently considered Vulnerable.*

[*Sturnella defilippii*, Bahía Blanca, Argentina. Photo: Sergio Seipke]

species, largely because it was confused with the far more common and sympatric Chopi Blackbird. It was even suggested that specimens of this icterid were unusual intergeneric hybrids between *Chrysomus* and *Gnorimopsar*. A careful check of collected specimens by L. L. Short and K. C. Parkes in 1979 clarified the distribution and systematic position of Forbes's Blackbird, but virtually nothing was known of its natural history. In the early 1980s, however, the species was rediscovered at Pedra Talhada, in Alagoas, and in 1988 A. Studer and J. Vielliard reported two small and disjunct populations, the one at Pedra Talhada, and another at Rio Doce, in Minas Gerais. The Alagoas population was estimated at 150 individuals, living around a relict forest patch. Soon thereafter, the species was found at other sites in Alagoas, with records from Usina Serra Grande, from near Matriz de Camaragibe, and from a forest area near Murici known as Pedra Branca, as well as from sugar-cane plantations and pastures bordering forest at Engenho Coimbra. Just to the north, in Pernambuco, the species has now been recorded at Usina Trapiche and at Mata do Estado, with flocks of up to 709 individuals observed, and at São Vicente Ferrer and Engenho Água Azul, in Timbaúba, and the species is said to occur at an additional nine localities in Pernambuco. This icterid appears again more than 1400 km to the south, in Minas Gerais, where up to 40 have been reported from the confluence of the Piracicaba and Doce rivers, and the species has been observed also near Pirapora and on the edge of the Cavernas do Peruaçu National Park.

This species clearly has an extremely fragmented range, and its total population is surely small and is thought to be declining. It is listed as Endangered. It is threatened by habitat loss, a problem compounded by the fact that it is captured for the pet and cagebird trade. Probably a more serious threat, however, at least in some localities, is parasitism by the Shiny Cowbird. At Pedra Talhada, 64% of Forbes's Blackbird nests were parasitized by this cowbird during 1981–1986, and in 1987 brood parasitism of the icterid reached 100%. The recruitment rate for the blackbird was found to be very low.

The last two globally threatened members of the family are the Saffron-cowled Blackbird and the Pampas Meadowlark. Both are inhabitants of grassland in southern South America and both are Vulnerable, having suffered substantial range reductions owing to habitat loss. In 1879, when the Argentinian army conquered the last of the Indian territories, the expedition scientists A. Doering and P. G. Lorentz found the Pampas Meadowlark to be the most abundant and characteristic icterid of the Buenos Aires *pampas* between latitudes 37° and 38°30' S. In this stronghold it inhabited the almost pure grasslands of the undulating plains. Outside Buenos Aires, this icterid was reported to breed in the provinces of Santa Fe and Entre Ríos, and perhaps even in Uruguay, as late as the 1950s. Since then, the distribution of the Pampas Meadowlark has steadily declined, and today most of

*Until very recently, the **Baudo Oropendola** was known from only five localities in north-western Colombia, including the headwaters of the River Acandí, where a breeding colony was recorded in 1991. This species may be naturally scarce. The kind of open-canopy forest that it seems to prefer, growing on sandy deposits along rivers and on coastal plains, is often the first to be lost to conversion and settlement. In 2010, two new colonies, totalling 70–80 individuals, were found about 120 km from Ensenada de Utría National Park, in an area where deforestation is accelerating. The Baudo Oropendola is considered Endangered.*

[*Psarocolius cassini*, W Antioquía, Colombia. Photo: Fundación ProAves/ Alonso Quevedo]

More than 95% of the population of the globally Endangered ***Tricolored Blackbird*** *breeds in the US state of California. In 2010, the total population was put at 395,000 individuals, barely half the number estimated for the seven Sacramento Valley counties alone in the 1930s. Considerable variation in estimates since the 1990s, however, suggests that this is a difficult species to survey. Up to 17% of the population breed in silage fields, a disastrous choice since these are harvested while the young are still in the nest. As breeding success is much higher in non-native upland vegetation than in native wetlands, conservation measures must address agricultural and upland habitats, too.*

[*Agelaius tricolor*, S California, USA. Photo: Dave Maslowski/ Maslowski Productions]

its population is concentrated in a small area at the southern edge of its former range, at the Sierras de la Ventana, north-west of the city of Bahía Blanca. Smaller populations have been reported from other sites, including the San Luis province of Argentina and parts of Uruguay, but their breeding status is unknown. There are also four winter records from south-east Brazil. A recent survey by P. Tubaro, F. Gabelli and co-workers showed that the remaining meadowlark population in Ventana far exceeds the previous estimate of 7500 individuals. Further populations were found in the sierras, with estimated total numbers of more than 20,000 individuals. Nevertheless, the species is still suggested as being Vulnerable, as it has a comparatively small and declining population within a small range. Conversion of natural grasslands for agriculture is causing rapid declines in the area of suitable habitat, with inevitable impacts on population size. The replacement of natural grasslands with crops and planted pastures, the main reason for the decline, may even affect its last stronghold; Pampas Meadowlarks nest mostly, or exclusively, on native grasslands. In addition, this meadowlark is not found within any national or provincial parks or reserves. The species' current breeding range is estimated at 16,600 km², a reduction of about 90% since 1900

Within the same general area of South America, the decline of the Saffron-cowled Blackbird is reasonably well documented. This icterid usually lives in or near wet grasslands, but it tolerates grazing and forages in agricultural fields. According to Hudson, it was found even in the rural suburbs of Buenos Aires city up to the 1880s. At that time the species was much more widely distributed, ranging from Paraguay and south Brazil southwards over much of the northern half of Argentina and most of Uruguay. The more drastic range retraction has occurred within Argentina. Here, this icterid became extinct in the late nineteenth century over most of Buenos Aires Province, where the last nesting attempt was observed in 1932; nowadays, it is found mostly in small areas of Entre Ríos and Corriéntes. Outside Argentina, it has small populations in eastern Paraguay, south-east Brazil, mostly in the state of Rio Grande do Sul, and south and east Uruguay, especially the Bañados del Este Biosphere Reserve. The global population is estimated at 2500–9999 mature individuals, but may not exceed 5000 individuals. Saffron-cowled Blackbirds are highly gregarious, and the large flocks reported in the past should be interpreted with care; it is possible that this was never an abundant species. In Entre Ríos, in Argentina, the total population estimate for 1997 was 250–500 individuals, and yet flocks containing more than 100 birds were seen in the winter. In 1879, the scientific expedition of Doering and Lorentz to the *pampas* of southern Buenos Aires reported only two groups of this blackbird, one of about 20 individuals and the other even smaller, during a 250-km transect across the pristine grasslands.

Due to their colourful plumage, Saffron-cowled Blackbirds are captured for the illegal cagebird trade during the breeding season, and this may disrupt or destroy entire nesting colonies. Another important threat to the species is the large-scale replacement of grasslands by pine and eucalypt (*Eucalyptus*) plantations, a practice that simply destroys its habitat. Drainage of wetlands probably had a major role in the extinction of populations in Buenos Aires Province. The species is also parasitized by Shiny Cowbirds, but this threat was already reported in 1881. The decline of the Saffron-cowled Blackbird is probably due to several factors, possibly exacerbated by the species' relative rarity. It is found in some protected areas in Uruguay, Paraguay and Brazil.

It is worth noting that a decline in grassland species has been recorded in most parts of the world, but it is in South America that the problem is of greatest concern. One factor that is often cited is that of burning. A recent experimental study by M. V. Petry and L. Krüger in Rio Grande do Sul focused on the way in which fire influenced the use of foraging habitat and breeding habitat by Saffron-cowled Blackbirds, which forage in grasses and nest in marshes. It was found that the blackbirds utilized the burnt areas more frequently and generally avoided areas of tall grass with other vegetation. In this region of south-east Brazil, fire has been used for centuries as a tool in the management of cattle, and in the study area short grasses are the result of such practices. The Saffron-cowled Blackbird depends on the existence of marshes surrounded by short grasses, using the latter for foraging. Because the period when burning is carried out coincides with the species' breeding season, the local landowners' unawareness of ecological factors and their inability to control fires pose a real threat to these populations.

In north-east Argentina, the Aguapey river basin in the *pampas* grasslands is the last refuge for a whole array of globally

*The Endangered **Yellow-shouldered Blackbird** was once widespread in Puerto Rico, but is now restricted mostly to south-western coastal areas. Brood parasitism by the Shiny Cowbird* (Molothrus bonariensis) *greatly reduced its numbers and resulted in most pairs breeding on offshore cays. In 1984 an artificial-nest programme was initiated, combined with the removal of cowbirds. From 1996 to 1999, only 22 of 804 nests in artificial structures and one of 203 nests in natural substrates were parasitized. Pre-breeding roost counts from 1985 to 1995 showed annual increases of 14%, and the population in 1998 was estimated at 1250, up from a low of 300.*

[*Agelaius xanthomus xanthomus*, Cabo Rojo, Puerto Rico. Photo: Eladio M. Fernández]

threatened bird species. A. S. Di Giacomo and colleagues, in an interesting and useful study, evaluated the influence of landscape characteristics on the occurrence of six threatened and Near-threatened passerines. Saffron-cowled Blackbirds were associated with rolling country in which, predictably, wet lowland grasslands and marshes were linked with dry upland grasslands; so, also, were Black-and-white Monjitas (*Xolmis dominicanus*). The grasslands of the Aguapey basin are exploited mainly for livestock grazing and afforestation. Since 1995, about half of the original grassland habitat has been planted with non-native trees. The authors believe that, if this trend continues, the Saffron-cowled Blackbird will probably become extinct in the Aguapey river basin, which currently holds the largest population of this icterid in Argentina. Various conservation measures have been proposed, including, among others, the establishing of appropriate reserves and protected zones, the creation of a land-use plan for the basin, the avoiding of planting trees in large blocks, and the removal of government incentives for large afforestation projects.

*Now rare and extremely local, the **Colombian Mountain Grackle** occurs mainly along the western slope of the east Andes of Colombia. At least 80% of its epiphyte-rich humid montane oak forests have been logged or converted to pasture, and many of the sites at which it was recently recorded are being rapidly deforested. Suitable habitats exist in the inaccessible upper elevations of the Yariguíes mountains, where the core population is probably at least 800 individuals. Elsewhere in its range, the population is small and severely fragmented.*

[*Macroagelaius subalaris*, Reserva Nacional de las Aves Reinita Cielo Azul, Santander, Colombia. Photo: Nick Athanas]

Only one member of Icteridae is listed as Near-threatened. The St Lucia Oriole, restricted to one small Caribbean island, has an extremely small global range and a very small population, thought to be nearer the lower end of the range 1000–2500 mature individuals. Although scarce, it is reasonably widespread on the island in dry scrub, coastal vegetation, plantation forests and edges, and both primary and secondary forests. Since the 1930s, this oriole has decreased in number and become more local, the probable cause being a combination of habitat loss, pesticide-spraying, brood parasitism by Shiny Cowbirds and harassment by Spectacled Thrushes (*Turdus nudigenis*). Rates of cowbird parasitism may be very high locally, up to 75% of broods consisting partially or exclusively of Shiny Cowbirds, but it is not known what effect, if any, this may be having on the oriole's present populations. There is no evidence that the St Lucia Oriole is declining or is under any threat, and its population is thought to be stable. Its population trends, however, are poorly known and should be monitored.

Apart from the "official" international listing of species of conservation concern, other measures of status are sometimes revealing. One such case involves Audubon's Oriole (*Icterus graduacauda*). This species' distribution is mostly in north-east and south Mexico, but the subspecies *auduboni* extends northwards into south Texas, in the extreme south USA. Local populations of this taxon along the Rio Grande in Texas and Tamaulipas, in adjacent north-east Mexico, have declined as a result of clearance of woodlands for irrigated agriculture; brood parasitism by Bronzed Cowbirds may represent an additional problem. It has now disappeared from most of the Lower Rio Grande Valley, including protected areas, and in *The American Bird Conservancy Guide to Bird Conservation*, published in 2010, this icterid is classed as "Rare" in the USA (Yellow WatchList priority species for conservation).

Some distinctive races of icterids have also suffered drastic declines. In the Cayman Islands, the subspecies *bairdi* of the Jamaican Oriole became extinct in the 1960s, for reasons that remain largely unknown; it even inhabited gardens in towns. It was smaller and brighter in colour than the nominate race of Jamaica.

It may seem odd that a parasitic cowbird could be regarded as being threatened, but the Bronze-brown Cowbird may come in that category. It has a very restricted distribution in the Caribbean lowlands of the north Colombian departments of Atlántico, Bolívar and Magdalena, where it is extremely local, and the total population must be small. The reasons for this cowbird's restricted range are not clear, as its dry woodland habitat extends well into Venezuela. It is present in the Isla de Salamanca National Park, in Magdalena. The natural history of this cowbird is almost entirely unknown. Most non-Colombian authorities treat it as a well-differentiated subspecies of the far more widespread Bronzed Cowbird.

It is clear that cowbirds have on the whole proved to be very successful species. Indeed, it is believed that the Brown-headed Cowbird has, during recorded history, achieved a greater natural expansion of range than any other native North American bird species. The cowbird's recent range extensions have coincided with declines in several other native species, and these have often been blamed on cowbird parasitism. As a consequence, control programmes have been set up and thousands of cowbirds are killed every year in an attempt to save a number of threatened passerine species. It has been suggested that, although some of this control may be appropriate, much of it may be a waste of time and money. Evidence that Brown-headed Cowbirds have an adverse impact on common North American species is at best minimal, but cowbirds

Molecular-genetic data indicate that the highly distinctive ***Red-bellied Grackle*** *evolved in isolation for four million years. Known from all three Andean ranges in Colombia, it now has a small and fragmented population and is Endangered. Habitat clearance is one cause of its decline, but increases in forest cover in some areas have failed to result in population growth, suggesting that other factors are involved. Sometimes persecuted as a pest in maize* (Zea mays) *crops, it is also trapped for the cage bird trade. Recent new locations for the species include Amalfi, in Antioquia. It is reported as quite common in mountains around Medellín, and common at four reserves in Antioquia. Its current known range includes several other protected areas.*

[*Hypopyrrhus pyrohypogaster*, Amalfi, Colombia. Photo: Pete Morris]

In 2010, the four island subspecies of what was then called the "Greater Antillean Oriole" were elevated to species rank. Historically, the ***Bahama Oriole*** *was found on the Bahamian islands of Abaco and Andros. For unknown reasons, the Abaco population disappeared in the early 1990s, and recent surveys found just 127 orioles on Andros. With an estimated global population of fewer than 250, the new species immediately qualified as Critically Endangered. Lethal yellowing disease has wiped out the coconut palm* (Cocos), *in which the orioles nest, in much of north Andros, and nests are parasitized by the newly arrived Shiny Cowbird* (Molothrus bonariensis).

[*Icterus northropi*, Stafford Creek, Andros, Bahamas. Photo: Stephen Myers]

do undoubtedly pose a potentially serious threat to two species and two subspecies that suffered greatly from habitat loss during the twentiethy century. The taxa in question are Kirtland's Warbler, the Black-capped Vireo (*Vireo atricapilla*), race *pusillus* of Bell's Vireo (*Vireo bellii*), known as the Least Bell's Vireo, and the south-western race *extimus* of the Willow Flycatcher (*Empidonax traillii*). Cowbird control is a major component of the recovery programme for these endangered passerines, and was decidedly effective when it was first introduced. However, S. I. Rothstein has suggested that, in each case, the controlling of cowbird numbers has gone too far and that it now creates potentially harmful consequences, in addition to the obvious ethical problems that arise from the killing of thousands of Brown-headed Cowbirds, a native songbird, every year. Rothstein adds that, in the case of *extimus* Willow Flycatchers, it is difficult to detect any population benefits that have been gained since control began in California, Arizona and New Mexico; in most instances, the results of cowbird control were large increases in the production of young, but no clear growth in the numbers of breeding individuals.

Shiny Cowbirds, too, have expanded into new areas in South America and have also extended northwards into the Caribbean region. More recently, this species has reached the south-west USA, and it is expected to continue to expand its range as it encounters more and more suitable habitats. It is well adapted to artificial environments and is found in almost all open habitats, avoiding unbroken forest and dense woodland. The opening-up of previously closed forest habitats has benefited this and other cowbird species, enabling them to spread into areas where they were formerly absent. In Brazil, the Screaming Cowbird has spread northwards as far as the Tocantins–Maranhão–Bahia border, following its principal host species in Brazil, the Chopi Blackbird.

Woodland clearance and the creation of artificial habitats can sometimes benefit other species, as well as cowbirds. One example of this can be seen in South America, where the Peruvian Meadowlark (*Sturnella bellicosa*) has recently succeeded in expanding its area of distribution as a result of the conversion of woodlands into pastures.

The ***Montserrat Oriole*** *once occurred in all the main montane forests on Montserrat, but has declined greatly through a combination of human pressures and natural catastrophes. Volcanic eruptions and ashfalls in the mid-1990s destroyed most of the remaining forest, and the oriole is now restricted to two patches of 14 km² and 1–2 km². The volcano remains active, but the current main threat is nest predation by Pearly-eyed Thrashers* (Margarops fuscatus) *and introduced rats* (Rattus). *A protected area has been established in the Centre Hills, where the main population survives, and eradication of rats has begun. Recent evidence suggests some population recovery, but its future in the wild is uncertain and it is listed as Critically Endangered. There are captive-breeding groups at Jersey Zoo and elsewhere.*

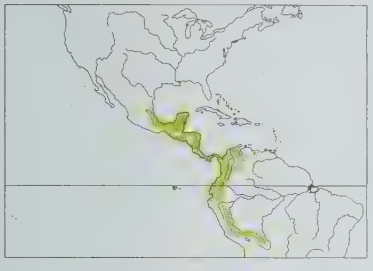
PLATE 71

inches 4
cm 10



Genus *AMBLYCERCUS* Cabanis, 1851

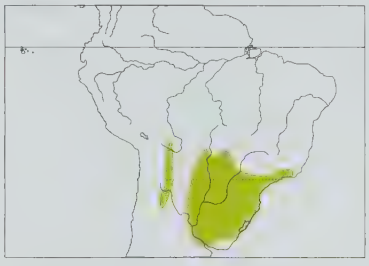
1. Yellow-billed Cacique

Amblycercus holosericeus

French: Cassique à bec jaune **German**: Gelbschnabelkassike **Spanish**: Cacique Piquiclaro
Other common names: Chisel-billed Cacique/Blackbird; Prevost's/Chapman's Cacique (*australis*)

Taxonomy. *Sturnus holosericeus* W. Deppe, 1830, Alvarado, Veracruz, Mexico.
Affiliation uncertain. DNA and skeletal data, also nest structure, indicate that this species is not related to true caciques (*Cacicus*); even its inclusion within present family has been questioned. Genetic distance between nominate race and *australis* suggests that two separate species may be involved; races appear to differ little in nesting habits and voice; examination of *flavirostris* required. Three subspecies currently recognized.
Subspecies and Distribution.
A. h. holosericeus (W. Deppe, 1830) – SE Mexico (S Tamaulipas) and across C America S to NW Colombia (Cartagena).
A. h. flavirostris Chapman, 1915 – Pacific lowlands from W Colombia (Chocó) S to N Peru (Tumbes).
A. h. australis Chapman, 1919 – Santa Marta Mts (N Colombia), Sierra de Perijá and coastal mountains of C Venezuela (Distrito Federal), and Andes from SW Venezuela S to Peru and C Bolivia (Santa Cruz).

Descriptive notes. Male 21·5 cm and 68·6 g, female 20·5 cm and 53 g; male 50·3 g, female 47·3 g (*australis*). Male nominate race has plumage entirely black, with minimal gloss; iris pale yellow; bill long, chisel-shaped at tip, yellow, nostrils covered with characteristic flap; legs grey. Female is similar to male but smaller, with plumage slightly slaty, less pure black. Juvenile is duller black than adult, with dark iris. Races differ in size and bill colour: *flavirostris* is smaller than nominate and has brighter yellow bill; *australis* is even smaller, with longer tail, and with more slender yellow bill with grey base. Voice. Series of paired loud whistles, "sh-wheu", female sometimes may answer with dry harsh "chrrr" in a kind of duet; may vocalize from the nest. Also a nasal call.
Habitat. Dense thickets, including bamboo, often near streams; thick undergrowth in secondary forest, abandoned agricultural clearings in forest, also weed-covered fields. In highlands (particularly Andes) found mostly in dense *Chusquea* bamboo stands. Occurs form sea-level up to 1500 m, but reaching 3100 m in Panama and Costa Rica (nominate race); 1500–3500 m in Andes (*australis*).
Food and Feeding. Mostly insects, e.g. Orthoptera, bugs (Hemiptera), Hymenoptera and beetles (Coleoptera) in stomach contents; also other arthropods, possibly small vertebrates, rarely fruit (*Inga*). Forages mostly in dense vegetation, using "gaping" action (open-bill probing), and even hammering, to extract prey from leaves and stems, or from rotten wood. Once observed while following army ants (Formicidae) in Panama. Forages in pairs and in family groups; follows mixed-species foraging flocks.
Breeding. Season Apr–Jun in Costa Rica, Jun in Colombia and Dec in Ecuador. Apparently monogamous. Nest in Costa Rica a bulky cup of plant material, e.g. strips of banana leaves, dry vines and leaves, and grass, sometimes with black fungal rhizomorphs incorporated, external diameter 12–15 cm, internal depth 6–6·5 cm, placed over tree crotch or attached to stems and vines, 1–2·5 m above ground in dense vegetation; a nest in Ecuador was an open cup with external diameter 12–13 cm and external depth 9·5 cm, built from *Chusquea* bamboo leaves and lined with pale fibres, attached 2·6 m above ground to three bamboo stems with long, thin vine tendrils and dead herbaceous material in 1·5-ha patch of *Chusquea*. Clutch 2 eggs, pale blue with black spots and lines around large end, mean dimensions 26·9 × 18·3 mm (Costa Rica) and 27·1 × 19·3 mm (Ecuador); in Ecuador only one adult observed during early incubation, later other adult (presumed the male) fed incubating individual (presumed female); both parents feed chicks; no information on duration of incubation and nestling periods. Frequent host of *Molothrus aeneus*, at least locally; five parasitized nests in Costa Rica contained 3–5 cowbird eggs and 0–2 host eggs.
Movements. Apparently sedentary; possibly some altitudinal movements in highlands.
Status and Conservation. Not globally threatened. Fairly common to uncommon and local. Tolerant of partial deforestation; uses dense second growth for nesting. Present in many protected areas.
Bibliography. Freeman & Zink (1995), Gómez (1983), Greeney, Jaffe & Manzaba (2008), Hilty (2003), Howell & Webb (1995), Kiff (1973), Kratter (1993), Lanyon & Omland (1999), Ridgely & Greenfield (2001a, 2001b), Russell (1964), Schönwetter & Meise (1982), Skutch (1954, 1996), Stiles & Skutch (1989), Webster (2003), Wetmore *et al.* (1984).



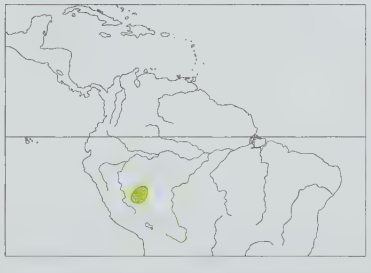
Genus *CACICUS* Lacépède, 1799

2. Golden-winged Cacique

Cacicus chrysopterus

French: Cassique à épaulettes **German**: Goldschulterkassike **Spanish**: Cacique Aliamarillo

Taxonomy. *Xanthornus Chrysopterus* Vigors, 1825, Brazil.
Formerly placed in genus *Archiplanus*, as *A. albirostris*; when included in present genus, however, that name becomes preoccupied. Has been regarded as closely related to *C. koepckeae*, with the two possibly forming a superspecies; also close to *C. sclateri*. Monotypic.
Distribution. E Bolivia (Santa Cruz) and S Brazil (from Mato Grosso do Sul and Rio de Janeiro) S to N Argentina (Tucumán, Catamarca, Santa Fe and Entre Rios) and NW Uruguay.



Descriptive notes. Male 20·7 cm, 34·6–47·2 g; female 19·3 cm, 30·2–34 g. Plumage is black overall, with bright yellow patch on lower rump and bright yellow patch on wing (median and inner greater upperwing-coverts); iris pearly white to yellow; bill pale bluish-grey; legs black. Sexes similar, female slightly smaller than male. Juvenile is duller than adult, and with dark eyes. Voice. Song variable, rather musical; usually starts with lower-pitched notes, followed by sudden crescendo, e.g. "dreow-deo-deo-psiklée-o". Male bows while singing. Paired birds may communicate with low-pitched whistles or warbles with odd harmonics. Appears at times to mimic other birds. Contact call an ascending, rasping nasal "aa-ah".
Habitat. Mountain forests (yungas) on humid Andean slopes, reaching almost timber-line in the alder (*Alnus*) or *Podocarpus* zone; also forest edge, humid and mesic *chaco* woodland, and transitional *chiquitano* forest. In E inhabits Atlantic Forest, from pristine-looking to degraded, and found also in second growth. In drier parts of range (C Chaco), partial to riparian or gallery forests. Up to 2800 m in humid mountain forests (S yungas) in Andes; mostly above 400 m in E Brazil.
Food and Feeding. Insects and other invertebrates, small vertebrates, also fruits and nectar. Stomach contents included small beetles (Coleoptera) and lepidopteran caterpillars. Wild fruits eaten include those of the trees *Alchornea glandulosa* and *Cabralea canjarana*, also of *Rhipsalis* epiphytic cacti, and arils of the vine *Chamissoa altissima*; feeds also on cultivated fruits, e.g. guavas (*Psidium*), oranges (*Citrus*), mulberries (*Morus*). Nectar obtained from flowers of epiphytic and terrestrial bromeliads (e.g. *Bromelia* and *Aechmea*), also from *Fuchsia*. Commonly probes and gapes into bark and epiphytes, and opens hollow twigs and insect galls; in Misiones (NE Argentina), seen to search webs built by tent caterpillars (*Malacosoma*). May hang upside-down while foraging. Mostly arboreal, frequently in mixed-species foraging flocks, commonly with *Icterus pyrrhopterus* and other icterids. Usually in pairs or family groups, but also reported also in flocks of 30 individuals, sometimes even more, in non-breeding season or during altitudinal movements.
Breeding. Season Oct–Dec in Argentina. Monogamous; solitary nester. Male commonly displays and sings around nest-site. Nest built by female, a long purse (45–60 cm long), open at top, almost always woven from thin blackish fibres, main material rhizomorphs of *Marasmius* fungus picked from bark of trees (particularly those of family Myrtaceae), sometimes mixed with horsehair, nest suspended from isolated branch tip, commonly over stream or small pond; sometimes built near older nests. Nest sometimes usurped by Piratic Flycatcher (*Legatus leucophaius*). Clutch 2–4 eggs, mostly 3, white with brownish spots, mean dimensions 24 × 16·6 mm; incubation by female alone, period 14–15 days; chicks fed by both parents, nestling period 18–19 days; family group persists for some months after young leave nest. Nests parasitized by *Molothrus bonariensis*.
Movements. Basically sedentary; some altitudinal movement in mountains of NW Argentina and (probably) Bolivia. Records from Buenos Aires (E Argentina) possibly involve vagrants, as nesting not reported from that province.
Status and Conservation. Not globally threatened. Rather abundant, particularly in mesic subtropical forests and woodland; rare or local in drier W Chaco of Bolivia, Paraguay and Argentina. Tolerant of light to medium disturbance of forest. Found in several protected areas, including Kaa-Iya del Gran Chaco and Amboró National Parks (Bolivia), Chaco, Mburucuyá, Río Pilcomayo, Finca El Rey and Calilegua National Parks (Argentina), San Rafael National Park (Paraguay) and Serra da Bocaina and Itatiaia National Parks (Brazil).

3. Selva Cacique

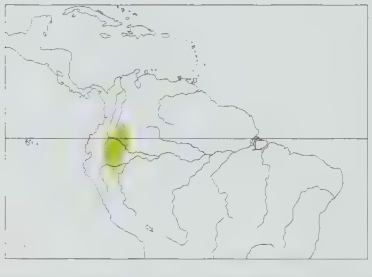
Cacicus koepckeae

French: Cassique de Koepcke **German**: Koepckekassike **Spanish**: Cacique de Koepcke

Taxonomy. *Cacicus koepckeae* Lowery and O'Neill, 1965, Balta, c. 300 m, south-east Ucayali, Peru.
Could been included in genus *Archiplanus*, if recognized. Morphological and biogeographical evidence indicate close relationship to *C. sclateri*; has been suggested that the two might be conspecific, but songs differ (though some calls similar). Has been regarded as close relative of *C. chrysopterus*, with the two perhaps forming a superspecies. Monotypic.
Distribution. W Amazonia in E Peru (Ucayali, Cuzco and Madre de Dios) and nearby W Brazil (Acre).

Descriptive notes. c. 23 cm. A slender, long-tailed dark cacique. Plumage is entirely black, except for bright yellow rump and uppertail-coverts; iris pale blue; bill pale bluish-grey; legs black. Sexes similar. Juvenile undescribed. Distinguished from superficially similar congeners by combination of yellow rump and blue bill and eye colours. Voice. Song during display at nest c. 2·4 seconds, consists of 2–4 similar introductory notes followed by two whistles or by a whistle and a buzzing note. A frequent call consists of alternate high-pitched and low-pitched staccato notes, "legs-cheow".
Habitat. Found mostly in dense riparian vegetation along small rivers or creeks flowing through forested foothills, often in *quebradas* (ravines); riparian vegetation includes dense growth of the "paca" bamboo *Guadua*, and also the giant cane-like grass *Gynerium saggitatum*, as well as medium-sized trees such as *Cecropia*, balsa (*Ochroma*

On following pages: 4. Ecuadorian Cacique (*Cacicus sclateri*); 5. Northern Mountain Cacique (*Cacicus leucoramphus*); 6. Southern Mountain Cacique (*Cacicus chrysonotus*); 7. Subtropical Cacique (*Cacicus uropygialis*); 8. Scarlet-rumped Cacique (*Cacicus microrhynchus*); 9. Red-rumped Cacique (*Cacicus haemorrhous*); 10. Yellow-rumped Cacique (*Cacicus cela*); 11. Band-tailed Oropendola (*Ocyalus latirostris*); 12. Casqued Oropendola (*Clypicterus oseryi*); 13. Solitary Cacique (*Procacicus solitarius*); 14. Yellow-winged Cacique (*Cassiculus melanicterus*).



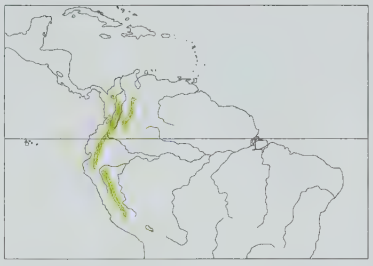
pyramidale), and leguminous trees e.g. *Erythrina poeppigiana*, *Zygia* and *Inga*. Has also been reported along larger rivers and *cochas* (oxbow lakes). At 300–700 m.
Food and Feeding. Diet little known. Feeds on nectar of *Erythrina* and *Inga* flowers. Forages mostly 1–5 m above ground; seen also seen in canopy, searching *Erythrina* seed pods. Usually in small groups of up to six individuals, possibly families; roosts with other icterids, particularly oropendolas.
Breeding. Nests found during Jul (dry season). Breeds as isolated pairs. Possibly co-operative breeder, as small groups of 3–5 individuals seen to visit nests; at one nest, a third cacique visited and did some nest-guarding, and the trio chased and attacked other icterids, notably *C. cela* and *Psarocolius decumanus*. One member of pair (presumably female) brought all nesting material, escorted by its mate, which sang and displayed on branch supporting nest; nest a slender pensile bag c. 60 cm long, main material blackish hyphae of *Marasmius* fungus, probably with other fibres incorporated, one was suspended from branch of *Zygia* tree 6 m above stream (the Arroyo Sepriato, in Cuzco), another was hanging from thorny *Mimosa* creeper growing over a small tree 10 m over water of same stream, both nests would have been flooded in rainy season. No other information.
Movements. Apparently sedentary.
Status and Conservation. VULNERABLE. Restricted-range species: present in South-east Peruvian Lowlands EBA. Rare and local; possibly overlooked. Known range in Peru fragmented; thought to occur also in adjacent W Brazil (Acre). Was formerly known from only three localities within tiny area of E Peru; has recently been located in at least one additional protected area. This species' preferred habitat appears to be riparian vegetation and riverine forest, and recent spatial models suggest that its distribution could be more extensive than currently known, and perhaps extend beyond 20,000 km². All records have been in areas of sparse human population, apparently not at imminent risk of habitat loss. Occurs in Manu National Park; presence in Santuario Nacional Megantoni recently confirmed, and may occur also in Cordillera Azul National Park. If fieldwork leads to discovery of further populations of this icterid in neighbouring areas, it could perhaps be downgraded to Near-threatened.
Bibliography. Anon. (2010d), Butchart & Stattersfield (2004), Buzzetti (2009), Cardiff & Remsen (1994), Gerhart (2004), Grilli *et al.* (2009), Jaramillo & Burke (1999), Lowery & O'Neill (1965), Ridgely & Tudor (1989), Schulenberg *et al.* (2010), Stattersfield & Capper (2000), Tobias (2003), Young *et al.* (2009).

4. Ecuadorian Cacique

Cacicus sclateri

French: Cassique d'Équateur **German**: Trauerkassike **Spanish**: Cacique Ecuatoriano
Other common names: Ecuadorian Black Cacique

Taxonomy. *Agelaeus sclateri* A. J. C. Dubois, 1887, Ecuador.
Has in the past sometimes been placed in genus *Archiplanus*. Morphological and biogeographical evidence indicate close relationship to *C. koepckeae*; has been suggested that the two might be conspecific, but songs differ (though some calls similar). Monotypic.
Distribution. W Amazonia from S Colombia (Serranía de la Macarena) S to E Ecuador and N Peru (Loreto).



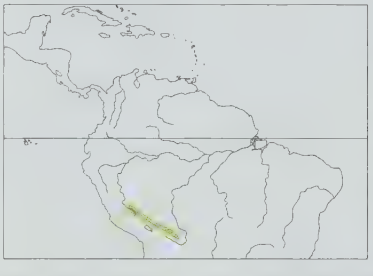
Descriptive notes. Male 23 cm, mean 57 g; female 19·5 cm, 49 g. A slender, long-tailed cacique. Plumage is entirely black, occasionally with a few yellow feathers in rump; iris pale blue; bill usually bluish-grey, sometimes dark horn-coloured; legs black. Differs from similar *Procacicus solitarius* mainly in smaller size and blue (not dark) eyes. Sexes similar. Juvenile (known from a single specimen) duller black. VOICE. Song typically transcribed as "wa-hu-kléé-ó" and variants, somewhat resembling that of *Procacicus solitarius*. Calls include "kip-cheew" and loud "chak-chak", similar to those of *C. koepckeae*.
Habitat. Lowland forests and forest edge near water; reported from oxbow lakes. Lowlands and foothills mostly below 400 m, rarely up to 750 m.
Food and Feeding. Insects, including ants (Formicidae), caterpillars, and beetles (Coleoptera); also fruit and possibly nectar. Forages in canopy, sometimes descending to lower levels. Singly and in pairs. Sometimes joins mixed-species flocks.
Breeding. Breeds in Jan in Colombia. Solitary nester, presumably monogamous. Possibly a co-operative breeder; three individuals reported as visiting one nest. Nest a purse up to 100 cm long, open at top, woven from dark rhizomorphs of *Marasmius* fungus, suspended from branch tip; two consecutive nests were in tree growing within an oxbow lake. Clutch 2 eggs, white. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Upper Amazon–Napo Lowlands EBA. Fairly common to locally not uncommon; sometimes rated as rare and local, but easily overlooked. Found in Tinigua National Park (Colombia) and in Pacaya-Samiria National Reserve (Peru).
Bibliography. Botero (2001), Cadena *et al.* (2000), Hardy *et al.* (1998), Jaramillo & Burke (1999), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schulenberg *et al.* (2010).

5. Northern Mountain Cacique

Cacicus leucoramphus

French: Cassique à bec blanc **German**: Nordandenkassike **Spanish**: Cacique Montano Norteño
Other common names: Golden-shouldered Cacique; Mountain Cacique (when treated as conspecific with *C. chrysonotus*)

Taxonomy. *Xanthornus leucoramphus* Bonaparte, 1845, "Bogotá".
Formerly placed in genus *Archiplanus*. Often considered conspecific with *C. chrysonotus*. Two subspecies recognized.
Subspecies and Distribution.
C. l. leucoramphus (Bonaparte, 1845) – Andes of W Venezuela (Táchira) and Colombia (all three cordilleras) S to SE Ecuador (Loja).
C. l. peruvianus J. T. Zimmer, 1924 – E slope of Andes of Peru (Amazonas S to Junín).
Descriptive notes. Male 28 cm and 98 g; female 25 cm and 64·5 g (nominate). Male nominate race is mostly glossy black, with bright yellow wing patch (median and inner greater upperwing-coverts), lower back and rump; concealed pale semi-collar formed by white bases of black feathers (perhaps exposed during display); iris blue; bill greenish-ivory, base bluish-grey; legs grey to black. Female is like male, but duller black overall. Immature has dark brown iris and darker bill than adult. Race *peruvianus* is heavier-billed and has less well-developed collar than nominate. VOICE. Noisy. Commonest calls are repetitions of loud notes with several harmonics, resembling calls of jays (Corvidae) or even hawks (Accipitridae); also a descending "fee-ooow" whistle, 2700–2050 Hz, and groups of 2–3 similar notes sounding like "frío-frío-frío". Duets reported. Song of a male near nest described as pig-like squeals followed by high-pitched notes and accelerating into a rattle.



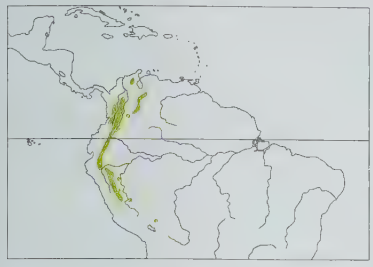
Habitat. Subtropical to temperate, humid montane forests. Reported to prefer forest with species of *Weinmannia* and *Clusia*. At 2000–3600 m (nominate race); 2000–3300 m in S of range (*peruvianus*).
Food and Feeding. Appears to feed mostly on insects and other arthropods; stomach contents include unidentified fruits. Forages in canopy and forest edge, actively probing into bamboo, epiphytes and bark. Found singly, in pairs, and in small flocks of 5–10 individuals; often in mixed-species foraging flocks with *Cyanolica* jays or *Buthraupis* mountain tanagers, also with *Hypopyrrhus pyrohypogaster*.
Breeding. Season Feb–Jul in Colombia. Apparently breeds solitarily or in small colonies: in Cundinamarca, Colombia, reported as solitary nester, with suggestion of co-operative breeding; in Ecuador, cluster of six active nests found near Baeza, but of three nests rather close together in Volcán Tungurahua only one was active. Nest an elongated bag c. 50 cm long, entrance at top, built from coarse plant materials, suspended from branch at medium height above a slope. No further information.
Movements. No information. Possibly some altitudinal movement.
Status and Conservation. Not assessed. Scarce or local in Venezuela and Colombia; uncommon to fairly common in Ecuador; fairly common in Peru. Has relatively large geographical range. Not reported as a host of *Molothrus oryzivorus*, probably because it occupies higher elevations.
Bibliography. Cuadros (1988), Hilty (2003), Hilty & Brown (1986), Jaramillo & Burke (1999), McCarthy (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schulenberg *et al.* (2010), Skutch (1996).

6. Southern Mountain Cacique

Cacicus chrysonotus

French: Cassique montagnard **German**: Mittelandenkassike **Spanish**: Cacique Montano Sureño
Other common names: Bolivian Cacique; Mountain Cacique (when treated as conspecific with *C. leucoramphus*)

Taxonomy. [*Cassicus*] *Chrysonotus* d'Orbigny and Lafresnaye, 1838, Yungas, La Paz, Bolivia.
Formerly placed in genus *Archiplanus*. Often considered conspecific with *C. leucoramphus*. Monotypic.
Distribution. Andes of Peru (from Junín) S to C Bolivia (Santa Cruz).



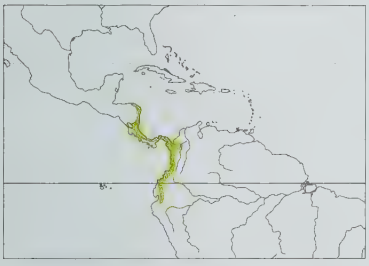
Descriptive notes. c. 28–30 cm; male 92·5 g, female 66·5 g. Male is mostly glossy black, with lower back and rump yellow; some have some yellow feathers in upperwing-coverts; iris blue to bluish-white; bill ivory-coloured, base bluish-grey; legs black. Differs from *C. leucoramphus* mainly in lack of concealed white collar, usually no yellow in wing-coverts, and has longer bill. Female is similar to male, but duller black overall. Immature is like adult, but eyes dark brown. VOICE. Repeated loud call notes, similar to those of *C. leucoramphus* but slower, softer and higher-pitched. A more complex vocalization of 5 notes, possibly a song, in which low-pitched throaty notes alternated with high and low whistles.
Habitat. Subtropical to temperate, humid montane forests, at 1800–3300 m.
Food and Feeding. Appears to feed mostly on insects and other arthropods; also takes nectar and fruits. Forages in canopy or forest edges, actively probing into epiphytes and bark; also in bamboo. Found in small flocks; often in mixed-species foraging flocks with *Cyanolica* jays or *Buthraupis* mountain tanagers.
Breeding. Fledglings seen in Oct–Jan in Bolivia. No other information.
Movements. No information. Possibly some altitudinal movement.
Status and Conservation. Not assessed. Fairly common. Estimated geographical range based on spatial models would cover c. 58,000 km². Occurs in Carrasco National Park and Amboró National Park, both in Bolivia.
Bibliography. Fjeldså & Krabbe (1990), Jaramillo & Burke (1999), Mayer (2010), McCarthy (2006), Restall *et al.* (2006), Schulenberg *et al.* (2010), Young *et al.* (2009).

7. Subtropical Cacique

Cacicus uropygialis

French: Cassique à dos rouge **Spanish**: Cacique Subtropical
German: Nord-Scharlachbürzelkassike
Other common names: Curve-billed Cacique

Taxonomy. *Cassicus uropygialis* Lafresnaye, 1843, Bogotá, Colombia.
Sometimes regarded as conspecific with *C. microrhynchus*, but differs vocally. Monotypic.
Distribution. Sierra de Perijá, and Andes from W Venezuela (Táchira) and Colombia (all three cordilleras) S on E slopes to Peru and NW Bolivia (La Paz).
Descriptive notes. Male 29 cm, 68 g; female 25 cm, 53 g. Rather long-tailed cacique with long, slightly decurved bill. Male is mostly jet-black with slight bluish gloss, and with red patch in lower back and rump; iris light blue; bill ivory-coloured, tinged slightly yellow at base and slightly greenish on rest; legs black. Female is less glossy than male. Juvenile is duller than adult, with dark eyes.



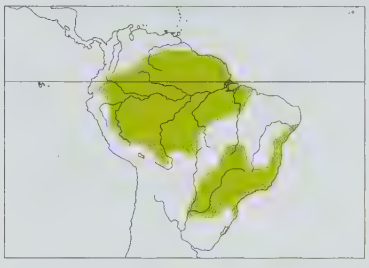
Voice. Song described as a series of whistles. Has variety of calls, one consisting of a three-part warble (1600–2100 Hz), another of sharp "keap!" notes.
Habitat. Humid subtropical montane forest, also forest edges; at 1000–2450 m.
Food and Feeding. Insects and other arthropods; also fruit and nectar, and known to take *Cecropia* fruits. Forages up to canopy level. Usually in small flocks; commonly found in mixed-species foraging flocks with other icterids, such as mountain caciques and *Psarocolius angustifrons*, or with *Cyanolica* jays.
Breeding. Reported as nesting in small colonies of up to twelve bag-shaped nests, hanging from isolated trees in ravines. No other information.
Movements. No information. Possibly some altitudinal movement.
Status and Conservation. Not assessed. Common to locally abundant. Has apparently extensive geographical range. Not likely to be globally threatened.
Bibliography. Hennessey & Gomez (2003), Hilty (2003), Hilty & Brown (1986), Jaramillo & Burke (1999), McCarthy (2006), Parkes (1970), Renjifo (1999), Restall *et al.* (2006), Ridgely & Tudor (1989), Salaman *et al.* (2002).

8. Scarlet-rumped Cacique

Cacicus microrhynchus

French: Cassique à bec mince **Spanish**: Cacique Lomiescarlata
German: Süd-Scharlachbürzelkassike
Other common names: Small-billed Cacique; Pacific Cacique (*pacificus*)

Taxonomy. *Cassiculus microrhynchus* P. L. Sclater and Salvin, 1865, Panama Railway, possibly Lion Hill Station, Panama.
Sometimes regarded as conspecific with *C. uropygialis*, but differs vocally. It has been suggested that race *pacificus* merits treatment as a full species, on basis of vocal differences; further research required. Two subspecies recognized.
Subspecies and Distribution.
C. m. microrhynchus (P. L. Sclater & Salvin, 1865) – E Honduras S in Caribbean lowlands (in Costa Rica and Panama also locally in Pacific lowlands) to E Panama (San Blas).
C. m. pacificus Chapman, 1915 – E Panama (Darién) and Pacific lowlands of Colombia S to SW Ecuador (El Oro).



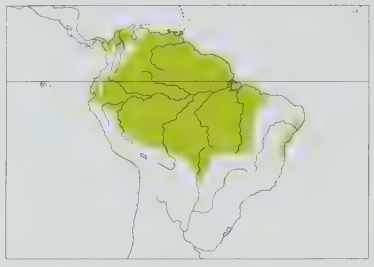
Descriptive notes. Male 23 cm and 62·5–71·7 g, female 20 cm and 50–57·6 g (nominate); male average 84·4 g, one female 61 g (*pacificus*). Nominate race is mostly black with slight gloss; small bright red patch on rump (often concealed by folded wings when bird perched); iris light blue; bill ivory-coloured, tinged slightly yellow at base and slightly greyish, bluish or greenish on rest; legs black. Sexes similar. Juvenile is duller than adult, with dark eyes. Race *pacificus* is similar in plumage to nominate, but larger, and with larger bill. Voice. Song of nominate race (by both sexes, from nest) a series of clear whistles, variable, sometimes shrill in tone and high-pitched, often a series of rising notes and then a sequence of falling notes. Songs of *pacificus* described as shorter, comprising four similar descending whistles; calls include a series of four loud modulated "wheo" whistles.
Habitat. Humid forest, primary forest and old second growth; also nearby shady plantations and clearings. Nominate race reported at up to 1100 m, and *pacificus* to 900 m.
Food and Feeding. Insects and other arthropods, small vertebrates, and fruit and nectar. Reported as raiding wasp (Vespidae) nests and eating the larvae. Known to feeds on arillate fruits of *Alchornea costaricensis* and nectar of *Marcgravia* vines. Mostly arboreal; often hangs upside-down while probing into crevices, bromeliads, dead leaves, and similar. Forages usually in groups of 4–10 individuals; commonly seen in mixed-species foraging flocks with oropendolas and other canopy passerines. Roosts in dense foliage in flocks of up to hundreds.
Breeding. Season Feb–Jun in Costa Rica and Feb–Aug in Panama; possibly double-brooded. Apparently monogamous. Solitary breeder in Costa Rica and most of Panama, though small colonies reported locally from C Panama (nominate race); *pacificus* reported as nesting in small colonies, but few data on this race. Nest built by female, taking 8–20 days, a purse 38–74 cm long, open at top, woven from brownish plant fibres (including roots and inflorescences), lined with seed down, suspended from tip of tree branch, including seasonally deciduous *Cordia alliodora*, or thorny pejibaye palm (*Bactris gasipaes*), sometimes hanging from lianas; often with wasp nest near nesting tree. Clutch 2 eggs, white with a few brownish and blackish spots and scrawls; incubation by female alone; chicks fed by both sexes; no information on duration of incubation and nestling periods; fledglings fed by both parents, and apparently sometimes also by other adults in post-breeding flocks.
Movements. Apparently resident.
Status and Conservation. Not assessed. Unlikely to be at any risk. Abundant in most of range. Found in several national parks and other protected areas, from Costa Rica S to Ecuador.
Bibliography. Hilty & Brown (1986), Jaramillo & Burke (1999), McCarthy (2006), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Skutch (1972), Stiles & Skutch (1989), Wetmore *et al.* (1984).

9. Red-rumped Cacique

Cacicus haemorrhous

French: Cassique cul-rouge **German**: Rotbürzelkassike **Spanish**: Cacique Lomirrojo

Taxonomy. *O.[riolus] haemorrhous* Linnaeus, 1766, French Guiana.
Mitochondrial DNA data indicate rather distant relationship with *C. cela*. Three subspecies recognized.
Subspecies and Distribution.
C. h. haemorrhous (Linnaeus, 1766) – SE Venezuela E to French Guiana, S to E Colombia, E Ecuador and N Brazil (Roraima).
C. h. pachyrhynchus Berlepsch, 1889 – Amazon Basin in Brazil (Amazonas and Pará S to Rondônia and NW Mato Grosso), E Peru and N Bolivia.
C. h. affinis Swainson, 1834 – E Brazil (Pernambuco and S Tocantins S to Santa Catarina), E Paraguay and NE Argentina (S to Corrientes).



Descriptive notes. Male 29 cm, average 96·5 g; female mean 25·2 cm, 62–74 g. A large, black cacique. Male nominate race is glossy black, apart from bright red lower back and rump; iris light blue; bill ivory-coloured; legs black. Female is duller in colour than male, with iris brownish-blue. Juvenile resembles female. Races differ mostly in iridescence of black plumage of male and in bill shape: *pachyrhynchus* has thicker bill than others; *affinis* is less glossy, with rump paler red, and has more slender bill. Voice. Loud, complex and varied repertoire of songs and calls, particularly among males. Vocalizations of race *affinis* include odd sibilant noises sounding like bellows, also low-pitched warbles, e.g. "wa-shee" etc. Perched male in display to nest-building female produces stereotyped "woody" grating song; louder warbling song (4–5 notes) shared by males around colony (colony noises of *affinis* audible at long distances). During nesting season solitary males away from colony (possibly non-breeding juveniles) give long, rambling subsongs. Alarm call a loud harsh "kak-kak-kak", taken up by all colony-members.
Habitat. Forest (both primary and second growth), clearings and plantations in forests, forest edges, and gallery forest. In N half of range more of a forest-dwelling species than *C. cela*. E race *affinis* found in gallery forest and large forest patches, and breeds even in small towns and suburbs. In non-breeding season confined more to forests. Lowlands to 900 m; race *affinis* to 1200 m.
Food and Feeding. Insects and other arthropods, also small vertebrates, fruit and nectar. Wild fruits taken (by race *affinis*) include *Cabralea canjarana*, *Ficus clusiifolia*, *Myrcianthes pungens*, and arils of *Cupania vernalis*. Feeds on nectar of *Pseudobombax* and other Bombacaceae, of *Erythrina* and of the vine *Mucuna* (Fabaceae). Nestling diet mostly insects, including large greenish katydids (Tettigoniidae) and mantises (Mantidae). Seeks food mostly on trees, also on lianas and epiphytes. Obtains nectar of *Mucuna* flower by inserting bill and opening mandibles (*Mucuna* has explosive flowers that open only when pressure applied on wings and keel); takes caterpillars of butterfly *Astraptes talus*, which pupate within these flowers. Known to pollinate flowers of *Mucuna japura*. Forages usually in groups or flocks, even during breeding; post-breeding flocks in Argentina can contain 80 or more individuals.
Breeding. Season Sept–May in Suriname and Aug–Jan in Argentina. Dominant males successively polygynous, pair-bond ending with start of incubation. Breeds in conspicuous colonies, usually of 20–30 nests in Amazonia; race *affinis* in colonies of 9–85 nests in Brazil and up to at least 100 nests in Argentina (Iguazú National Park); may form mixed colonies with *Psarocolius decumanus*, *Psarocolius viridis* and *C. cela* in N part of range (Amazonia, Suriname); in Brazil, Plain (*Pachyramphus validus*) and Chestnut-crowned Becards (*Pachyramphus castaneus*) may nest in colony trees. Perched male displays with a bow to nest-building female. Nest built by female, taking 5–11 days (nominate race) or average of 18 days (*affinis*), an elongated purse wider at bottom than at top, length 34–45 cm in Suriname, 47–65 cm in Argentina, entrance slit near top, woven from diverse plant fibres, in Argentina commonly including strips of green palm leaves (e.g. of *Syagrus romanzoffiana* and *Acrocomia totai*), also orchid rhizomes and ferns, race *affinis* usually incorporating black rhizomorphs of *Marasmius* fungus in inner nest fabric, nest lined with dry leaves, and suspended from branch or palm frond; late-season nests (possibly replacements) in Argentina appear shorter and more hastily built; colonies located in one to few isolated trees, commonly diverse tree species, even exotic pines (*Pinus*), also tree-ferns, and in Argentina and Paraguay mostly in the palm *Syagrus romanzoffiana* (one *Syagrus* palm in Iguazú National Park was used as colony site for at least 30 years), in E Brazil also in trees in marshes; in some areas nests near human habitations, even in towns (e.g. in NE Argentina), probably as anti-predator strategy. In Argentina nests commonly usurped by Piratic Flycatcher (*Legatus leucophaius*); abandoned nests sometimes used by *Icterus pyrrhopterus*. Clutch 2 eggs, whitish with reddish-brown spots and blotches, mean dimensions 28·4 × 19·6 mm (Argentina); in Suriname, incubation by female, period 17 days, chicks fed by female, very occasionally assisted by male, nestling period 25–28 days; in SE Brazil (race *affinis*) average incubation period 18·3 days and nestling period 23·4 days. Nests parasitized locally by *Molothrus oryzivorus*.
Movements. Apparently sedentary. In NE Argentina moves to more continuous forest during non-breeding season, visiting colony sites from time to time.
Status and Conservation. Not globally threatened. Relatively scarce in N half of range, where it is rarer than *C. cela*; rare and local in Ecuador and much of Amazonia. Race *affinis* far more abundant. Within its extensive range, this species is found in many national parks, e.g. Canaima National Park (Venezuela), Iguazú National Park (Argentina) and Itatiaia National Park (Brazil).
Bibliography. Agostini (2004), Agostini & Sazima (2006), Argel-de-Oliveira & Figueiredo (1996), Belton (1985), Chatellenaz & Ferraro (2000), Duca & Marini (2004, 2005, 2008), Dunham (1971), Feekes (1981), Fraga (2007, 2011), Haverschmidt (1972b), Hilty (2003), Jaramillo & Burke (1999), Oniki & Willis (1983), Parkes (1970), de la Peña (1987), Pizo (1996, 2009), Sick (1993), Wright & Ferraro (1985).

10. Yellow-rumped Cacique

Cacicus cela

French: Cassique cul-jaune **German**: Gelbbürzelkassike **Spanish**: Cacique Lomiamarillo
Other common names: Lawrence's/Saffron-rumped Cacique (*vitellinus*, *flavicrissus*)

Taxonomy. *Parus Cela* Linnaeus, 1758, "in Indiis"; error = Suriname.
Analysis of mitochondrial DNA indicates closer relationship with *C. uropygialis* than with *C. haemorrhous*, being genetically rather distant from latter. Races form two distinctive groups, separated by Andes: W group (*vitellinus* and *flavicrissus*) possibly represents a separate species, differing from single-species "*cela* group" in plumage colour and voice. Three subspecies recognized.
Subspecies and Distribution.
C. c. vitellinus Lawrence, 1864 – C Panama S to N & C Colombia (Santa Marta, Tolima).
C. c. flavicrissus (P. L. Sclater, 1860) – W Ecuador and extreme NW Peru.
C. c. cela (Linnaeus, 1758) – lowlands E of Andes from Colombia (including Caribbean coast near Santa Marta), most of Venezuela, Trinidad, and the Guianas S to C Bolivia (Santa Cruz) and S Brazil (Mato Grosso do Sul); also, coastal E Brazil (Pernambuco S to SE Bahia).
Descriptive notes. Male average 28 cm, 109·3 g; female average 23 cm, 71 g. Male nominate race is mostly black with slight bluish gloss; lower back, rump, uppertail-coverts and rear abdomen yel-

low; variable amounts of yellow in upperwing, affecting several greater coverts and some median coverts; uppertail mostly black from above with yellow at the upper edges, undertail yellow; iris blue; bill ivory; legs blackish. Female is like male, but smaller and duller. Immature has dark eyes. Race *vitellinus* has yellow parts of plumage richer, more orange-yellow, than nominate, also wing patch smaller, bill greyish at base; *flavicrissus* is very like previous, but smaller. Voice. A common call is a warbling "k'weu"; alarm call a series of harsh "kwack". Nominate race is an outstanding mimic of many birds, including parrots (Psittacidae), woodpeckers (Picidae), many passerines and others, and even of mammals; its variable song often starts with harsh double note, "k'wek-k'wok", followed by imitations (e.g. in Suriname and Bolivia); Suriname males have extensive song repertoire that slowly changes through time, including song themes typical of each respective colony. Male songs in Amazonian Brazil include grating sounds and a pleasant double phrase, "kw'héé-kwa'hu". Males of race *vitellinus* not known to mimic, but still have varied song repertoire; songs may sound like harsh falsetto notes, or pleasant low-pitched liquid warbles, or rhythmic phrases with nasal tone, and overall effect is less harsh and more pleasant than that of nominate songs.

Habitat. Forest edges, gallery forest, second growth, savanna, plantations, and pastures with large trees or palms. In Amazonia occurs in *várzea* and *terra firme* habitats, but more abundant in former; race *flavicrissus* occurs in Tumbesian xeric forest with annual precipitation of less than 600 mm. Lowlands and foothills, to 1000 m (nominate race).

Food and Feeding. Insects and other arthropods, small vertebrates, fruits and nectar. Stomach contents include caterpillars and Orthoptera. Fruits taken include those of *Cecropia*, and the epiphytic *Coussapoa*. Feeds on floral nectar from trees and lianas such as balsa (*Ochroma pyramidale*), bacuri (*Platonia insignis*), *Quararibea*, etc.; is a pollinator of bacuri, an economically important tree. Within forests feeds mostly in canopy or upper strata. Almost invariably in flocks.

Breeding. Breeds in Apr–May in Panama (race *vitellinus*); throughout year (but rarely in May–Jun) in Suriname, Nov–Jan in E Brazil (Pernambuco), and at least Jun–Sept in Bolivia. Male successively polygynous, pair-bond lasting until egg-laying. Colonial nester, with up to at least 100 nests per colony; sometimes *C. haemorrhous* and several species of oropendola nest in same trees. Nest built by female, taking 5–14 days, a purse (38–50 cm in length) with roofed entrance at top, woven from plant fibres, mainly strips of palm leaves, and suspended from branch tip; nests often clustered around nest of an aggressive wasp species (e.g. of genus *Synoeca*, *Polybia*, or other), which helps to repel predators; colonies in Amazonia and elsewhere sometimes located in trees growing on tiny islands, or in the water, and in some areas (the Guianas) colonies near human habitations, also probably as anti-predator strategy. Nests not uncommonly usurped by Piratic Flycatcher (*Legatus leucophaius*) and *Icterus croconotus*. Clutch usually 2 eggs, whitish with scattered black and reddish spots, mean dimensions 28·5 × 19 mm (nominate race) and 30·2 × 20·2 mm (*vitellinus*); incubation by female, period 16 days; chicks fed by female, rarely also by male, nestling period 24–28 days. Nests parasitized locally (e.g. Panama) by *Molothrus oryzivorus*; presumed case of parasitism by *Molothrus bonariensis* (on race *flavicrissus*) not well documented.

Movements. Mostly resident. In W Ecuador, populations of *flavicrissus* in xeric deciduous forest observed only during wet season.

Status and Conservation. Not globally threatened. Widely distributed and rather abundant, probably spreading and increasing in numbers with deforestation. Race *vitellinus* occurs in Soberanía National Park (Panama) and other protected areas. This species' role in pollinating economically important bacuri tree may be significant.

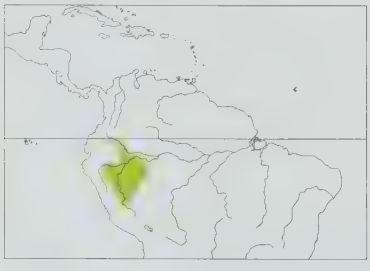
Genus *OCYALUS* Waterhouse, 1841

11. **Band-tailed Oropendola**



Ocyalus latirostris

French: Cassique à queue frangée **German**: Breitschnabel-Stirnvogel **Spanish**: Cacique Colibandeado

Taxonomy. *Cassicus latirostris* Swainson, 1838, Peru.

Genus sometimes subsumed in *Psarocolius*. In general morphology, size and behaviour appears closer to *Cacicus*, with voice rather like latter's. Mitochondrial DNA data, however, indicate close relationship with *Clypicterus oseryi*, the two forming a clade separate from the other oropendolas; a more distant relationship with *Cacicus haemorrhous* was weakly supported. Monotypic.

Distribution. W Amazonian lowlands in extreme S Colombia (around Leticia, in Amazonas), NE Ecuador, NE Peru (Loreto, Ucayali) and W Brazil (SW Amazonas and W Acre).

Descriptive notes. Male average 33·2 cm, 117·5 g; female average 24·5 cm, 74·8 g. Comparatively small oropendola looking all black at a distance, except for distinctive tail pattern in flight. Male has crown, nape and upper back dark chestnut; rest of plumage mostly velvety black, wing with bluish gloss; tail yellow with glossy black centre and tip, forming inverted T-pattern (usually concealed when bird perched); iris pale blue, rarely brown (possibly juvenile); bill variable, ivory-coloured with diffuse dusky wash around tip, or mostly dusky grey above, ivory-coloured below; legs black. Female is like male, but somewhat smaller and duller. Juvenile undescribed. Voice. Foraging calls described as liquid "chewop", "ke-cho" and "skeedelp-chop"; also a sharp "chiek". A more complex, two-part vocalization, "cho we-cho wo", with pleasant liquid tone, is probably the song. Repertoire and vocal timbre reminiscent of those of *Procacicus solitarius*.

Habitat. Amazonian floodplain-forest (*várzea*) along rivers, even on older islands; reported also in upland (*terra firme*) forest, but near rivers. Up to 300 m.

Food and Feeding. Stomach contents include unidentified fruits and caterpillars (Lepidoptera), but diet probably includes other arthropods, small vertebrates and nectar. Forages mostly below canopy. Often reported in mixed-species foraging flocks with *Psarocolius angustifrons* and *Cacicus cela*, and up to 50 individuals of present species reported in one such mixed flock in Brazil; rarely, in monospecific groups of 3–8 individuals.

Breeding. Season Aug–Sept in Peru and Brazil. Mating system seems monogamous to polygynous, but information on breeding minimal. Breeds solitarily or in colonies of up to 15–20 nests. One solitary nest in Brazil was a purse, open at top, similar in shape to that of *Cacicus haemorrhous*, woven from diverse plant fibres, built 17 m up and above a colony of *Clypicterus oseryi* in isolated *Cecropia* tree near small river; this nest contained chicks, fed by only one adult. No other information.

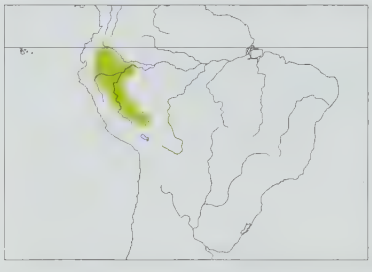
Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Very rare in Ecuador, where known from one old specimen and a few sight records; more abundant in Peru and Brazil; uncommon in Colombia. Occurs in some protected areas in Peru, e.g. Pacaya-Samiria National Reserve, and Brazil, e.g. Serra do Divisor National Park. May merit protected status in Ecuador.

Bibliography. Hardy *et al.* (1998), Hilty & Brown (1986), Jaramillo & Burke (1999), Price & Lanyon (2002b, 2004a), Remsen (1977), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Whitaker & Oren (1999).

Genus *CLYPICTERUS* Bonaparte, 1850

12. **Casqued Oropendola**



Clypicterus oseryi

French: Cassique casqué **German**: Helmstirnvogel **Spanish**: Cacique de Yelmo

Taxonomy. *Cassicus Oseryi* Deville, 1849, Pebas, Peru.

Genus formerly subsumed in *Psarocolius*, but mitochondrial DNA indicates that this species belongs to a separate clade together with *Ocyalus latirostris*; as its morphology is quite different from that of latter, a generic separation is recognized. Monotypic.

Distribution. W Amazonia from E Ecuador (Sucumbíos) and SE Colombia (Amazonas) S to E Peru, W Brazil (W Amazonas, Acre) and N Bolivia.

Descriptive notes. Male average 37 cm, 187·7 g; female average 29 cm, 101·4 g. Plumage is mostly rich chestnut, darkest on foreface, with greyish-olive throat and yellowish-olive upper breast and side of neck; upperwing chestnut, yellow edges of flight-feathers; tail dusky olive, outer feathers bright yellow; iris light blue, rarely pale yellowish-grey; bill variable, sometimes upper mandible dark grey, lower mandible yellow-green with dark grey tip, casque dull yellowish-grey to olivaceous grey, sometimes ivory-coloured with or without greenish tinge and with dark grey towards tip, sometimes entirely dark grey (variation in casque and bill colours perhaps related to age); legs black. Sexes similar but female much smaller, with smaller casque. Juvenile has dark eyes. Voice. Song variable, one type a "klow klow shrr-weo", with tonal quality of *Cacicus haemorrhous*; nesting colonies very noisy.

Habitat. Reported from both *várzea* and *terra firme* forests. Seems to breed mostly in *várzea* forests, in mid-successional to mature stages. Upland forest may be used mostly for foraging, or in non-breeding season. Lowlands to 400 m, locally to 750 m.

Food and Feeding. Diet probably arthropods, small vertebrates and nectar. Stomach contents include unidentified red berries. In Brazil seen to feed on fruits of a *Coussapoa* species (Moraceae). Reported as flocking with *Cacicus cela*. Roosts communally with other oropendolas and caciques.

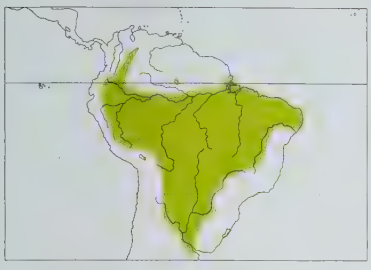
Breeding. Season Sept–Nov in Peru. Polygynous, but detailed studies of breeding lacking. Colonies of 14–25 nests, located along small rivers; breeding activities highly synchronized, e.g. all nests in colony of 19 nests were built in about a week; sometimes nests with *Ocyalus latirostris*. Nest built by female, a purse, open at top, woven from diverse brownish plant fibres, in shape resembling that of colonial *Cacicus* species; all known colonies in Peru and Brazil were in isolated *Cecropia* trees. Incubation of eggs by female; male parental role is mostly that of nest-guarding and defence of colony against monkeys, toucans (Ramphastidae) and other predators. No other information.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Uncommon to locally common. Has recently extended its range N to Colombia. Found in several protected areas, including Manu National Park and Biosphere Reserve and Tambopata–Candamo Reserved Zone (Peru), Serra do Divisor National Park (Brazil) and Madidi National Park (Bolivia).

Bibliography. Cuao-Carranza (2007), Jaramillo & Burke (1999), Koepcke (1972), Leak & Robinson (1989), Parker *et al.* (1991), Price & Lanyon (2002b, 2004a), Restall *et al.* (2006), Ridgely & Tudor (1989), Whitaker & Oren (1999).

Genus *PROCACICUS* Fraga, 2005



13. **Solitary Cacique**

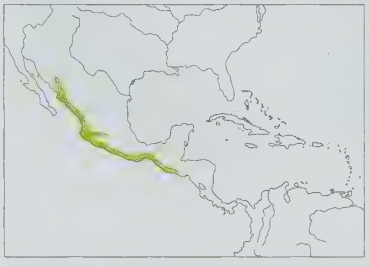
Procacicus solitarius

French: Cassique solitaire **German**: Stahlkassike **Spanish**: Cacique Solitario

Other common names: Solitary Black Cacique

Taxonomy. *Cassicus solitarius* Vieillot, 1816, Paraguay.
Formerly included in genus *Archiplanus*. Often placed in genus *Cacicus*, but analysis of mitochondrial DNA indicates that this species is more closely related to *Psarocolius* than to other caciques. Monotypic.
Distribution. SW Venezuela (Táchira, Apure) S through E Colombia (Meta), E Ecuador and E Peru, Brazil (locally N of R Amazon on R Branco, in Roraima, more extensively S of Amazon E to Ceará, Pernambuco and W Bahia) S to C & E Bolivia, Chaco of Paraguay, N & E Argentina (S to Santiago del Estero, Santa Fe and Buenos Aires) and W Uruguay (locally along R Uruguay).

Descriptive notes. Male average 27·5 cm, 90·1 g; female average 23·5 cm, 80 g. Plumage is entirely black, with slight gloss; iris brown to chestnut-brown, exceptionally bluish (museum specimens); bill ivory-coloured; legs black. Differs from *Cacicus sclateri* in iris and bill colours and larger size. Sexes similar. Juvenile is duller black than adult. Voice. Song variable, with considerable individual repertoires. Song around nest usually starts with a series of low-pitched notes, and may contain pipe-like hollow sounds, sudden crescendos and odd harmonics; songs in other contexts may be shorter and simpler; mimics other bird species. In territorial conflicts between pairs, all individuals may vocalize for periods of 30 minutes or more. A common call is a loud nasal "kwah-kwah"; also cat-like calls.
Habitat. Mostly occurs in flooded forest and gallery forest along rivers and channels, extending to dense riparian vegetation on islands of main rivers (Amazon, Paraguay, Paraná, etc.); also occupies swamp-woodland (e.g. Esteros del Iberá, in Argentina). In drier Chaco of Bolivia, Paraguay and Argentina occurs locally in seasonal deciduous woodland (typically with dense undergrowth of spiny bromeliads), but often near seasonal river channels (*madrejones*) and swamps (*bañados*), also near artificial reservoirs (*represas*). Lowlands to 600 m, rarely to 1400 m. Avoids most rocky terrain.
Food and Feeding. Insects and other arthropods; also small vertebrates, particularly tree-frogs (Hylidae); also fruits and nectar. Insects include e.g. beetles (Coleoptera), Lepidoptera, Hymenoptera, and bugs (Hemiptera); reported as using one foot to hold cases of bagworm moths (*Oiketicus*, Psychidae) while extracting the insect by means of open-bill probing. Takes both wild fruits, e.g. terrestrial bromeliads and myrtaceous *Hexachlamys edulis*, and cultivated ones, e.g. oranges (*Citrus*). Takes nectar from flowers of *Erythrina* and the vine *Combretum lanceolatum*. Forages mostly at lower levels of vegetation and in undergrowth (e.g. among terrestrial bromeliads); rarely on the ground, where it jumps, rather than walks. Commonly probes with open bill (gaping) and even hammers into dry or rotten wood, often spending considerable time in extracting such prey as carpenter ants (*Camponotus*) and beetle larvae. Non-gregarious, forages usually in pairs or family groups; rarely seen in mixed-species foraging flocks.
Breeding. Season Oct–Jan in C Brazil and Oct–Dec in Argentina; in Argentina reported as double-brooded. Monogamous. Solitary nester, but older structures may be found near active nests. Nest built by female, a purse up to 120 cm long, open at top, woven from diverse plant fibres, reported materials in Argentina including adventitious roots of the vine *Cissus palmata*, strips of leaves from terrestrial bromeliads (e.g. *Deinacanthum urbanianum*), epiphytic bromeliads (*Tillandsia usneoides*), bark fibres and strips of palm leaves (general appearance of greenish or straw-coloured, not blackish, structure), lined mostly with dry leaves; suspended 2–5 m above ground from isolated branch tip, frequently over water. Abandoned nests sometimes used by other icterids, such as *Agelaioides badius* and *Icterus croconotus*. Clutch 2 eggs, white with sparse dark markings, dimensions 29·5 × 19·9 mm; incubation by female, period 17 days; chicks fed by both parents, both also defend nest, nestling period 18–19 days; family group can persist for some months. Eggs of *Molothrus bonariensis* reported from abandoned nests, but possibly these nests had been utilized by another icterid species.
Movements. Apparently resident throughout range.
Status and Conservation. Not globally threatened. Rather common in S part of range (R Paraná and R Paraguay basins); less abundant elsewhere. Tolerates moderate habitat disturbance, in Argentina breeding regularly in coastal urban reserves of Buenos Aires city. Found in several protected areas in Argentina, e.g. Kaa-Iya del Gran Chaco National Park (Bolivia), Pantanal Mato-grossense National Park (Brazil), San Rafael National Park (Paraguay), and Río Pilcomayo, Chaco and Mburucuyá National Parks (Argentina).
Bibliography. Beltzer (1986), Chatellenaz & Ferraro (2000), Di Giacomo, A.G. (2005), Di Giacomo, A.G. *et al.* (2010), Fraga (2005a), Hartert & Venturi (1909), Hayes (1995), Hilty (2003), Jaramillo & Burke (1999), López-Lanús (2008), Naka *et al.* (2006), Nores *et al.* (1991), de la Peña (1987), Pereyra (1938), Remsen & Parker (1983), Serié (1932), Sick (1993), da Silva & Colombo Rubio (2007).



Genus *CASSICULUS* Swainson, 1827

14. Yellow-winged Cacique

Cassiculus melanicterus

French: Cassique à ailes jaunes **German**: Haubenkassike **Spanish**: Cacique Mexicano
Other common names: Crested/Mexican Cacique

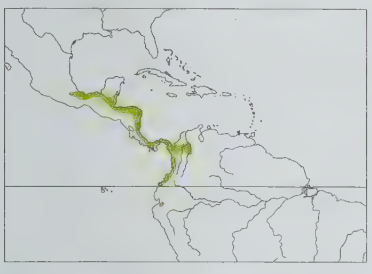
Taxonomy. *Icterus melanicterus* Bonaparte, 1825, Temascaltepec, Mexico.
Often placed in genus *Cacicus*, but preliminary mitochondrial DNA data suggest an ancestral position within the cacique–oropendola clade. Is a rather distinctive species, geographically isolated from other caciques, with habitat preferences somewhat different from those of latter, and with nest resembling those of oropendolas. For all those reasons, placement in its own monotypic genus seems appropriate. Monotypic.
Distribution. W Mexico from Sonora S along Pacific slope to Chiapas, extending inland along Balsas drainage to SW México; also S Guatemala and El Salvador.

Descriptive notes. Male average 31·7 cm, 96·3 g; female average 27·8 cm, 69·9 g. A large and slender cacique. Male is mostly glossy black, including conspicuous long nuchal crest; most of upperwing-coverts contrastingly yellow, lower back to uppertail-coverts yellow, crissum yellow; tail black, broadly edged with yellow; iris dark brown; bill ivory-coloured, with variable greyish, bluish or yellowish tinge; legs dark grey. Female has shorter crest than male, is smaller and duller, slaty grey instead of black, and yellow feathers of tail fringed olive. Juvenile lacks crest, has black areas of plumage dusky, yellow parts tinged with greenish; immature is like female, but more brownish. Voice. Song variable, often "krrow-krrow-kshárá-chee". Has many calls, including whistles and rattles; common call an ascending "whik".
Habitat. Edges and clearings in dry to mesic deciduous forest, thorn-scrub, savanna and pastures with large trees, and plantations. In El Salvador frequents either coastal mangroves or riparian habitat. Roosts apparently in mangrove patches.
Food and Feeding. Insects and other invertebrates, probably small vertebrates, also fruits and nectar. Reported as feeding on brush-shaped inflorescences of *Combretum fruticosum*. Extracts nectar from *Erythrina* flowers; feeds on nectar also of the bat-pollinated tree *Ceiba acuminata*. Food delivered to nestlings included green katydids (Tettigoniidae) and earthworms (Oligochaeta). May form mixed-species foraging flocks with jays, such as San Blas Jay (*Cyanocorax sanblasianus*), also with other icterids, e.g. *Dives dives* and *Quiscalus mexicanus*.
Breeding. Season May–Aug. Mating system not well known, possibly ranging from monogamy to moderate polygyny. Nests solitarily or in small colonies of up to ten nests, sometimes extending to several trees. Courtship display by male involves vertical raising of tail and expanding of wings and crest. Nest a purse, open at top, 60–80 cm in length, external diameter at widest point 18 cm, woven from diverse plant fibres, in El Salvador including coconut palm fibres (*Cocos nucifera*), pieces of slender vines (mostly Bignoniaceae), rootlets and grass, bottom lined with dry leaves and grass, suspended from branch tip 6–18 m above ground, mostly in tall isolated leguminous tree, in Mexico often *Enterolobium cyclocarpum* or *Pithecellobium dulce*; in El Salvador other trees used included native species such as *Albizzia niopoides*, also exotics such as eucalypts (*Eucalyptus*), and 40% of nesting trees were near rural houses; nests sometimes attached to telephone or electricity wires. Clutch 2–4 eggs, pale blue, lightly spotted and streaked with grey and black, mean dimensions 28·6 × 20·1 mm; no information on incubation and nestling periods; both sexes reported as feeding chicks in El Salvador. Nests frequently parasitized by *Molothrus aeneus*; of 12 nests in S Mexico (Oaxaca), 11 each held one or two cowbird eggs.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common to fairly common in most of range; rare in N. Has recently spread S and colonized S Guatemala and El Salvador, where possibly still expanding its range. Tolerates moderate habitat modification. Captured for cagebird trade in Mexico, with legal restrictions on season and quotas. Possible that escaped or released cagebirds have assisted its recent expansion. Present in several protected areas in Mexico, including e.g. Chacahua Lagoons National Park (Oaxaca) and Estación de Biología Chamela (Jalisco).
Bibliography. Baker *et al.* (1971), Dickerman (1960, 2007), Friedmann & Kiff (1985), Gryj *et al.* (1990), Howell & Webb (1995), Ibarra Portillo (2009), Jaramillo & Burke (1999), Komar & Dominguez (2001), Price & Lanyon (2004a), Rowley (1984), Urbina-Torres *et al.* (2009).

PLATE 72

inches 6

cm 15



Genus *PSAROCOLIUS* Wagler, 1827

15. Chestnut-headed Oropendola

Psarocolius wagleri

French: Cassique à tête brune **German**: Rotkopf-Stirnvogel **Spanish**: Cacique Cabecicastaño
Other common names: Wagler's Oropendola

Taxonomy. *C.[acicus] Wagleri* G. R. Gray, 1844, no locality = Guatemala.
Formerly placed in a monotypic genus *Zarhynchus* because of its peculiar bill shape; recent analysis of mitochondrial DNA indicates, however, that it belongs to a clade containing the "Andean oropendolas" (*P. atrovirens* and montane races of *P. angustifrons*). Two subspecies recognized.
Subspecies and Distribution.
P. w. wagleri (G. R. Gray, 1844) – Atlantic slope from SE Mexico (Veracruz and N Oaxaca) S to Honduras and NE Nicaragua.
P. w. ridgwayi (van Rossem, 1934) – E Nicaragua S to W Colombia and SW Ecuador (Manabí, rarely to El Oro).

Descriptive notes. Male average 35 cm, 214 g; female average 28 cm, 113 g. Slightly crested. Male nominate race has dark purplish-chestnut on head and down to central breast; body and wing black with bluish gloss, becoming dark chestnut on rump and uppertail-coverts, rear flanks to undertail-coverts (and sometimes thighs) chestnut; tail yellow, central feather pair black, outer rectrices with black edges; iris pale blue; bill is expanded into swollen casque, and is ivory-coloured, sometimes with slight greenish tinge, tip and band along cutting edge pale bluish to grey; legs black. Female is like male, but smaller, with duller colours. Juvenile is duller than adult, eyes brownish (or even brownish and blue), bill brownish, some yellow feathers in forehead. Race *ridgwayi* is very like nominate, but has chestnut parts of plumage paler. Voice. Song short, but variable, consists of low "pop" sounds followed by harsh, crashing noises (likened to sound made by a machete cutting vegetation). Frequent call (Costa Rica, Panama) a liquid, low-pitched "waku-waku". Male produces audible wing noise in flight.
Habitat. Prefers forests, but often found in clearings and edges. In Costa Rica more common in foothills than in Caribbean lowlands, and reaches wet mountain forests. Found also in tall secondary forest with *Cecropia* and balsa (*Ochroma pyramidale*), and in plantations, large parks and even suburbs (e.g. in Panama City). Lowlands up to 1200 m (nominate race); *ridgwayi* up to 1700 m in Costa Rica.
Food and Feeding. Small vertebrates (frogs and lizards), also insects and other arthropods; also fruit and nectar of large flowers, e.g. of balsa. Orthopterans and beetles (Coleoptera) found in stomach contents. Often forages high in canopy. Probes and gapes in epiphytes.
Breeding. Season Jan–Jun. Polygynous. Colonial, with 15–60 (exceptionally 130) nests per colony, often located on several isolated trees, e.g. colony spread over seven Cuban royal palms (*Roystonea regia*) in Panama, but in Mexico more often in a single tree; often in mixed colonies with *Cacicus cela* and *P. decumanus* in S of range (S from Panama). Nest built by female, a purse 60–120 cm long, open at top, woven from diverse plant fibres such as *Tillandsia*, strips of lianas, palm leaves, etc., lined with pieces of dry and green leaves, suspended from branch tip of variety of plants, from palms (native and exotic) to alder trees (*Alnus acuminata*) in Costa Rican highlands; if unmolested, may nest near buildings or road (e.g. in former Panama Canal Zone); some colonies built in trees having nests of aggressive wasps (of genus *Synoeca* or *Stenopolybia*). Clutch 2 eggs, pale blue with brownish-black markings, mean dimensions 32·6 × 21·9 mm; incubation by female, period 17 days; chicks fed by female, nestling period up to 35 days; males guard and defend colony. Nests parasitized by *Molothrus oryzivorus*.
Movements. Short-distance seasonal and altitudinal movements, probably related to availability of fruiting trees.
Status and Conservation. Not globally threatened. Locally common to uncommon. Found in several protected areas, including Braulio Carrillo and Tapantí National Parks (Costa Rica), Soberanía National Park (Panama), and Los Katíos National Park (Colombia).
Bibliography. Chapman (1928), Crandall (1914), Fleischer & Smith (1992), Fraga (1987b), Hilty & Brown (1986), Howell & Webb (1995), Jaramillo & Burke (1999), Leck (1974), Price & Lanyon (2002b), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Skutch (1954), Smith (1968, 1983), Stiles & Skutch (1989), Wetmore *et al.* (1984).

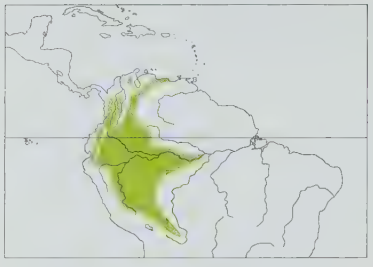
16. Dusky-green Oropendola

Psarocolius atrovirens

French: Cassique olivâtre **German**: Grünschnabel-Stirnvogel **Spanish**: Cacique Verdioscuro

Taxonomy. *Cassicus atro-virens* d'Orbigny and Lafresnaye, 1838, Yungas of La Paz, Bolivia.
Recent analysis of mitochondrial DNA indicates that this species belongs to a clade containing also *P. wagleri* and montane races of *P. angustifrons*. Monotypic.
Distribution. E slope of Andes from C Peru (Huánuco) S to C Bolivia (Cochabamba and Santa Cruz, also nearby ridges e.g. Serranía Mosetenes).
Descriptive notes. Male average 42 cm, 299·4 g; female average 33 cm, 156·6 g. Plumage is dark olivaceous throughout, paler on throat and ear-coverts, darker on lores and on wing, and becoming russet on rump, uppertail-coverts and undertail-coverts; central pair of rectrices dark olive, remainder yellow, outer rectrices with dark olive edges; some adults have yellow on forehead; iris variable, brown, dark grey or light blue (perhaps age-related); bill ivory-coloured with slight greenish tinge; legs dark plumbeous. Sexes similar, female smaller than male. Juvenile is duller than adult, bill paler and yellower, eyes brown, forehead yellow, crown dusky, throat yellowish-white, underparts greyer, and patches of pale greyish or cream-coloured down often visible in underparts. Voice. Songs simpler, more percussive and shorter than those of most congeners, seldom lasting for more than 1 second; much song variation among males, some starting with a sequence of low-pitched notes and ending with slashing sounds, shrill metallic notes, or other variants; males seem to have a repertoire of different songs. Common calls include rattles, a "jog" and a shrill "chwik".

Habitat. Dry to wet mountain forests, often along river canyons; also around settlements and fruit plantations. Breeds at 800–2800 m; observed down to 400 m during austral winter.
Food and Feeding. Diet not much studied; probably feeds on insects and other arthropods, small vertebrates, fruit and nectar. Catches moths (Lepidoptera) and other nocturnal insects attracted by lights; reported as preying on hummingbirds (Trochilidae). Feeds on both wild fruits (e.g. *Cecropia*) and cultivated fruits (bananas, papayas, oranges). Consumes nectar from *Erythrina* trees. Forages mostly in canopy or subcanopy, probing and searching in clusters of dead leaves or epiphytes; sometimes feeds on the ground. Forms mixed-species foraging flocks with jays, such as Purplish Jay (*Cyanocorax cyanomelas*).
Breeding. Season Oct–Dec. Perhaps less polygynous than other oropendolas, but in Bolivia males displayed along stretches of mountain streams containing two or more colonies. Nests in small scattered colonies of 2–10 nests; isolated nests reported, and small colonies frequently have just one active nest. Nest a purse 85–110 cm long, open at top, woven from diverse brownish plant fibres (roots, palm fibres, strips of banana leaves, etc.), lined with leaves, sometimes of bamboo, suspended from roots or branch of small tree or shrub growing in crevice of rocky cliff, usually 7–12 m above rushing water of mountain stream; some colonies on isolated trees, usually over narrow stream or mountain path. Clutch 1–2 eggs, pale greenish-white, marked and spotted in shades of dark brown, mostly at large end, mean dimensions 36 × 24·2 mm. No other information. Not reported as a host of *Molothrus oryzivorus*, although the two species co-exist at lower elevations.
Movements. Some altitudinal movement apparent during austral winter.
Status and Conservation. Not globally threatened. Uncommon to locally common. Estimated global range c. 71,700 km². Found in several protected areas, including Manu National Park and Tambopata–Candamo Reserved Zone (Peru) and Cotapata, Carrasco and Amboró National Parks (Bolivia). Regarded as a pest and persecuted by fruit-growers.
Bibliography. Brumfield & Maillard (2007), Fraga (2004), Graves (1978), Jaramillo & Burke (1999), McCarthy (2006), Niethammer (1956), Price & Lanyon (2002b, 2004a, 2004b), Ridgely & Tudor (1989), Young *et al.* (2009).



17. Russet-backed Oropendola

Psarocolius angustifrons

French: Cassique roussâtre **German**: Breithauben-Stirnvogel **Spanish**: Cacique Dorsirrufo
Other common names: Russet Oropendola; Black-billed Oropendola (*angustifrons*); Yellow-billed Oropendola (Andean races combined); Alfred's/Pale-billed Oropendola (*alfredi*); Oleaginous Oropendola (*oleagineus*); Olive-bellied Oropendola (*neglectus*)

Taxonomy. *Cassicus angustifrons* Spix, 1824, São Paulo de Olivença, south bank of upper River Solimões, west Amazonas, Brazil.
Taxonomy complex and confusing. Nominate race has blackish bill; the other six races, with yellow bill, may represent a distinct species. Recent fieldwork in foothills of Colombian E Andes revealed that race *neglectus* does not associate with nominate, the two behaving as separate species, and this supported by DNA studies indicating considerable sequence divergence between the four N Andean forms (Venezuela S to Ecuador) and nominate race; also, songs of some of N Andean races are distinctive. On other hand, DNA divergence between *alfredi* and nominate was relatively small, and songs of the two are similar, suggesting that they are conspecific (also, intermediate specimens reported from E Ecuador). Analyses of mitochondrial DNA indicate considerable divergence between some montane populations, which may deserve full species status, but a more detailed analysis of the full complex is needed. Proposed race *australis* (described from Santa Cruz, in C Bolivia) supposedly darker than *alfredi*, but considered to fall within range of variation of latter and therefore synonymized with it. Seven subspecies currently recognized.
Subspecies and Distribution.
P. a. oleagineus (P. L. Sclater, 1883) – mountains and foothills of coastal N Venezuela (from Carabobo E to Miranda).
P. a. neglectus (Chapman, 1914) – Sierra de Perijá (Colombia–Venezuela border); W Andes of Venezuela and E slope of E cordillera in Colombia (S to Caquetá).
P. a. salmoni (P. L. Sclater, 1883) – W & C Andes of Colombia (S to Nariño).
P. a. sincipitalis (Cabanis, 1873) – W slope of E Andes of Colombia (from Santander S to upper Magdalena Valley).
P. a. atrocastaneus (Cabanis, 1873) – W slope in Ecuador.
P. a. alfredi (Des Murs, 1856) – E Andean slopes and foothills from SE Ecuador (Morona Santiago) S to Peru and C Bolivia (Cochabamba and Santa Cruz).
P. a. angustifrons (Spix, 1824) – low E Andean foothills from S Colombia (S from Meta and Vaupés) S to E Ecuador and NE Peru (Loreto and N Ucayali) and W Brazil (Amazonian lowlands E to lower R Purús).
Descriptive notes. Male average 48 cm and 407 g, female 38 cm and 219 g (nominate); male average 46·5 cm and 284·3 g, female 36·2 cm and 172·7 g (*oleagineus*); two males 254 g and 278 g, six females 157–184 g (Venezuela). Nominate race has head olivaceous brown, body brown with russet tinge, becoming pale russet-brown on rump to uppertail-coverts; central rectrices dusky brown, remaining ones yellow, outer rectrices with dusky-brown edges and tips; iris dark brown; bill blackish; legs blackish. Sexes similar but female much smaller and lacks elongated nuchal feathers. Juvenile has head more yellow-tinged than adult, also yellow areas of tail duller. Races differ mainly in size and in colour of plumage, bill and eyes (irides tend to be blue in Ecuador, dark brown elsewhere): *oleagineus* is mostly yellowish-olive, back tinged rufous-brown, rump and undertail-coverts rufous-brown, also forehead more yellow (particularly on juvenile), central and outermost rectrices olive, remaining ones mostly yellow, bill greenish-ivory; *neglectus* is darker, with yellow superciliary lines, bill orange-yellow; *salmoni* is dark brown, blackish replacing olive in wings and

On following pages: 18. Crested Oropendola (*Psarocolius decumanus*); 19. Green Oropendola (*Psarocolius viridis*); 20. Amazonian Oropendola (*Psarocolius yuracares*); 21. Para Oropendola (*Psarocolius bifasciatus*); 22. Montezuma Oropendola (*Psarocolius montezuma*); 23. Black Oropendola (*Psarocolius guatimozinus*); 24. Baudo Oropendola (*Psarocolius cassini*).

tail, yellow on forehead more extensive, back chestnut, grading into russet on rump, bill ivory; *sincipitalis* is like previous, but paler; *atrocastaneus* is rufescent overall, with contrasting yellow forehead, orange-yellow bill, iris can be fully or partially blue; *alfredi* is more brownish-olive than last, paler and more yellowish-olive on head, with yellow forehead patch, body brownish-chestnut, becoming russet on rump and uppertail-coverts, central rectrices brownish-olive, remaining ones yellow with brownish-olive tips, bill pale greenish-yellow, eyes brown (Bolivia) or sometimes blue (Ecuador and N Peru). Voice. Male songs during bow displays shorter (0·7–1·7 seconds) and simpler than those of congeners, but individually and regionally variable. Song usually starts with low-pitched notes and increases in pitch and volume in a final crescendo. The species' Ecuadorian vernacular name *Cucupacho*, stressed either as "cucupachó" or "cucupácho", a good imitation of songs in E Ecuador, Peru and Bolivia; male *neglectus* song a crescendo, "up-up-rup chéó"; male *atrocastaneus* songs more distinctive and longer, with guttural notes, and ending in ringing rattles. Calls include harsh "chak" as alarm, and soft "whep" for contact.

Habitat. Nominate race occurs mostly in floodplain-forest (*várzea*) along "white-water" rivers, such as the Putumayo, Napo, Marañón–Amazonas and Ucayali; found in the earlier arboreal stages of riverine forest, particularly in *Cecropia* stands, and around oxbow lakes, but invades clearings in mature forest. Race *alfredi* inhabits *várzea* of S Peru and Bolivia, also forests, plantations and second growth along humid Andean foothills. Other races found in subtropical, wet montane forest, extending also to nearby plantations and clearings. Lowlands, locally to c. 2000 m in E Ecuador (nominate); 1000–2100 m in W Ecuador (*atrocastaneus*); 400–1800 m in N Venezuela (*oleagineus*); generally to 2500 m in Andes.

Food and Feeding. Almost omnivorous. In N Venezuela (race *oleagineus*), known to eat insects, small vertebrates (frogs), and nectar of *Erythrina*. Stomach contents of nominate race include wild fruits of *Cecropia* (of several species in *várzea*) and *Coussapoa*. In Chapare (Bolivia) *alfredi* feeds on many cultivated fruits, from oranges to papayas, and takes nectar from balsa flowers (*Ochroma pyramidale*). Often captures prey in epiphytic bromeliads or in "aerial litter". Forages in flocks, sometimes with other oropendolas and with *Cacicus cela*; montane races may flock with jays (Corvidae).

Breeding. Season Mar–Jun in N Venezuela (race *oleagineus*) and Sept–Mar in lowland Colombia (nominate); nest-building starts Jun–Jul and eggs and chicks found in Aug–Dec in C Bolivia (*alfredi*). All races polygynous. Colonial breeder, usually 2–20 nests often spread over 3–5 adjacent trees (not clustered), with up to three dominant males per colony; race *alfredi* in small colonies of up to 14 nests, 1–4 males visiting and displaying in colony; nominate race in Colombia in larger colonies (up to 29 nests), usually on isolated trees growing on small islands or in oxbow lakes, and may form mixed colonies with *Cacicus cela*, either in same tree or in nearby one. Nest built by female, taking 3–5 weeks, replacement nests (smaller and/or of poorer quality) may be built in 12 days; a purse 75–150 cm long, open at top, woven from coarse, brownish plant fibres, mostly from leaves of monocot plants such as Bromeliaceae, bananas (Musaceae), Cyclanthaceae and similar, lined with coarse wider fibres, suspended from branch tip or hung from epiphytic aroids (Araceae), usually 5–10 m above ground; several wild and cultivated species of medium-sized tree, including *Cecropia* and fruiting trees, are utilized; race *alfredi* builds in wide variety of medium-sized, wild and cultivated trees, particularly peach palms (*Bactris gasipaes*), commonly in trees growing in clearings and plantations, even in towns. Clutch 1–2 eggs, white to pale greenish white, variably marked with spots and lines of brown and reddish-brown, mean dimensions 36·5 × 24·2 mm; incubation by female, period 19–20 days; chicks fed by female, nestling period 30–32 days; male parental care limited to colony-guarding. Some nests in lowlands and foothills may be parasitized by *Molothrus oryzivorus*. Success variable; only one chick reared per nest in some populations.

Movements. Apparently sedentary in lowlands; otherwise some altitudinal movement.

Status and Conservation. Not globally threatened. Generally common in lowlands; uncommon to locally common in Andes. N Venezuelan race *oleagineus* is abundant in Henri Pittier National Park. Some Andean races may have declined in some parts of range; nominate race and *alfredi* able to adapt to human-modified environments and have increased in numbers.

Bibliography. Areta (2009b), Fraga & Kreft (2007), Hardy *et al.* (1998), Hilty (2003), Hilty & Brown (1986), Jaramillo & Burke (1999), McCarthy (2006), Niethammer (1956), Price & Lanyon (2002b, 2004a, 2004b), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Robinson, S.K. (1985a, 1988a, 1997), Salaman *et al.* (2002), Schäfer (1957, 1986), Zimmer (1930).

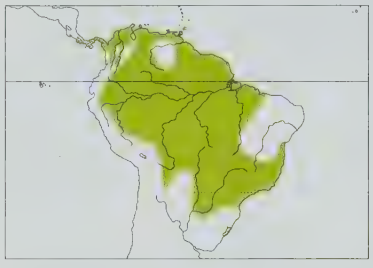
18. Crested Oropendola

Psarocolius decumanus

French: Cassique huppé **German**: Krähenstirnvogel **Spanish**: Cacique Crestado

Taxonomy. *Xanthornus decumanus* Pallas, 1769, Suriname.

Relationships uncertain; somewhat isolated from other members of genus. Birds from S of R Amazon sometimes treated as race *maculosus* (described from Yungas of Cochabamba, in Bolivia), but DNA data do not support this, showing only a certain distinctiveness for Andean populations. Three subspecies currently recognized.



Subspecies and Distribution.

P. d. melanterus (Todd, 1917) – S Costa Rica, Panama, and N & W Colombia (W of E Andes).

P. d. decumanus (Pallas, 1769) – Colombia (E of Andes), Venezuela and the Guianas, S on E slope of Andes and S across Amazonia to N & E Bolivia, NW & NE Argentina (S to Jujuy and Salta and, in E, to Formosa and Corrientes) and E Brazil (S to N & W Paraná and São Paulo).

P. d. insularis (de Dalmas, 1900) – Trinidad and Tobago.

Descriptive notes. Male average 47 cm, 284·6 g; female average 37 cm, 158 g. Male nominate race is black overall, with slight gloss, becoming chestnut on rump, uppertail-coverts and undertail-coverts; a few thin feathers form small black crest; tail yellow, central feather pair black; birds from region of Bolivia, C Brazil, Paraguay and N Argentina ("*maculosus*") frequently have variable number of pale yellow feathers in body, but this character sometimes shown by individuals from elsewhere (e.g. Venezuela); iris blue; bill is expanded into casque, and is ivory to pale yellow; legs black. Female is like male, but smaller and somewhat duller, with much of plumage brownish-tinged (not pure black); crest greatly reduced and generally not visible in field. Juvenile resembles female, but still duller, with eyes dark brownish, bill tinged brown. Races differ little: *melanterus* is more glossy black and less chestnut than nominate; *insularis* is smaller and more chestnut than others. Voice. Male song during display usually starts with low-pitched liquid notes, accelerates into variable and complex rattling crescendo, and ends with 2–3 seconds of rhythmic wing-flaps (wing-flapping noise not reliably reported for other oropendolas). Gives repeated harsh "kak-kak-kak" in alarm.

Habitat. Edges and clearings of tropical, subtropical and lower montane forests, also in second growth, gallery forest (particularly in the Pantanal and in Paraguay), savanna and plantations with large trees. Over most of its range, not regularly found in unbroken primary forest. Lowlands and low hills, generally below 1000 m; nominate race mostly below 1700 m, rarely to 2600 m.

Food and Feeding. Diet fruits, insects and spiders (Araneae); also small vertebrates, such as tree-frogs (Hylidae); also floral nectar. Consumes both wild fruits (*Cecropia*, *Cayaponia*, *Cordia*) and cultivated fruits (oranges, papayas, mangos). Insects in stomach contents include beetles (of families Cerambycidae and Curculionidae) and caterpillars. Takes nectar from flowers of several trees, commonly *Erythrina*, also from the vine *Combretum lanceolatum*. Forages mostly in trees, in upper stratum, rarely in lower strata or on ground. Will join mixed-species foraging flocks with other icterids and jays (Corvidae).

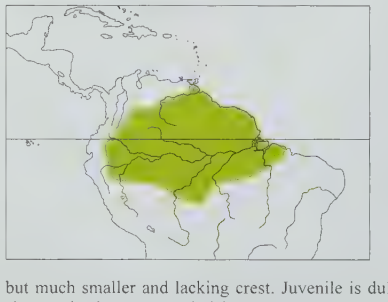
Breeding. Season Jan–Jun in Venezuela and Oct–Dec in NW Argentina. Breeds in colonies of 2–43 nests, most colonies having fewer than ten nests, largest colonies reported from NW Argentina and Trinidad (where it is the only member of its genus); reported in mixed colonies with caciques and several congeners. Displaying male performs a deep bow while singing. Nest built by female, a purse 70–160 cm long (replacement nests of same female usually shorter), open at top, and having characteristic elongated pyriform shape, rather neatly woven from diverse plant fibres (strips of lianas, palm leaves, fibres from bromeliads, etc.), lined mostly with dry leaves, and suspended from high branch tip of tree, usually an isolated one, and in gallery forest (Paraguay and NE Argentina) often over river or channel; some nests in Amazonian Bolivia included blackish *Marasmius* rhizomorphs in the attachment, and fibres of Spanish moss (*Tillandsia usneoides*) also reported; females steal nest material from each other, also from nests of other birds, including *Cacicus chrysopterus*. Nests sometimes usurped by Piratic Flycatcher (*Legatus leucophaius*). Clutch 2 eggs, bluish-white, pale grey or buff with blackish spots and lines, mean dimensions 35·9 × 24·5 mm; incubation by female, period 17–19 days; chicks tended by female, nestling period 28–34 days; male parental care limited to colony-guarding. One of the most important hosts of *Molothrus oryzivorus* throughout much of range (records from Trinidad and Venezuela S to N Argentina); alleged record of parasitism by *Molothrus bonariensis* in Argentina invalid.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Common in much of range; scarcer in S of range. Recently invaded Costa Rica. Has increased in NW Argentina. Declines recorded in NE Argentina, where now rare in Misiones, and in SE Brazil, where formerly extended S to Santa Catarina. Extirpated in Cauca Valley and some other areas of Colombia. The most widespread and ecologically tolerant oropendola; apparently able to tolerate partial deforestation more than are its congeners. Present in many protected areas, e.g. Henri Pittier National Park (Venezuela), Pantanal National Park (Brazil), Amboró National Park (Bolivia) and Calilegua and Baritú National Parks (Argentina), among others. Regarded as an agricultural pest in fruit orchards and plantations in Trinidad, Venezuela, NW Argentina and other regions, and locally persecuted.

Bibliography. Abe (1996), Allen (1891), Di Giacomo & López-Lanús (2000), Drury (1962), ffrench (1991), Fraga (2002), Guimaraes (1926), Haverschmidt (1972b), Hilty & Brown (1986), Jaramillo & Burke (1999), Price & Lanyon (2002b, 2004a, 2004b), Ragusa-Netto (2002a), Ramírez-Llorens *et al.* (2003), Reidy (2009), Sandoval *et al.* (2010), Schäfer (1957, 1986), Schubart *et al.* (1965), da Silva & Colombo Rubio (2007), Skutch (1996), Tashian (1957).

19. Green Oropendola



Psarocolius viridis

French: Cassique vert **German**: Grünschopf-Stirnvogel **Spanish**: Cacique Verde

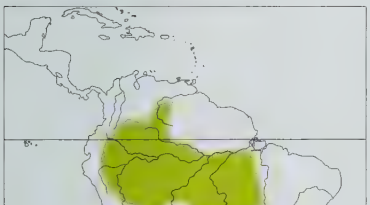
Taxonomy. *Oriolus viridis* Statius Müller, 1776, Cayenne, French Guiana.

Analysis of mitochondrial DNA indicates present species is closer to *P. yuracares* than to *P. decumanus*. Populations in NE Peru sometimes separated as race *flavescens* (described from Xeberos, in E Peru), but this separation seems unwarranted. Monotypic.

Distribution. E & S Venezuela, the Guianas, and SE Colombia (Vichada and Amazonas), E Ecuador, E Peru and N Bolivia (E Pando) E across most of Amazonian Brazil (E to Marajó I and W Maranhão, S to N Rondônia).

Descriptive notes. Male average 48·5 cm, 405 g; female average 37 cm, 215 g. Male has head to back and most of underparts yellowish-olive, a few thin feathers forming small green nuchal crest; small bare area on lores and around eye pink to dull orange; wing dusky olive, rump and uppertail-coverts, belly, thigh and crissum chestnut; tail yellow, central feather pair and outer edge of outermost pair dusky olive; iris pale blue; bill is expanded into casque, and is pea-green with orange-red distal half; legs blackish. Differs from similar *P. yuracares* in colours of back and wing, eye and bill, and bare parts of face. Female is like male, but much smaller and lacking crest. Juvenile is duller than adult, with greyish wash below, less chestnut in plumage, eye dark brown. Voice. Male songs variable and complex, usually more musical than those of congeners. In Venezuela loudest part of song (1–2 seconds long) consists of liquid up-and-down rhythmic motifs, e.g. "glop-glop-glop-glup-glup" and the like, forming a bass line with narrow pitch range (400–950 kHz), complex harmonics on top of this creating tonal quality of a wooden percussion instrument (such as a marimba). Other males change harmonics through a second, higher-pitched motif, producing mild dissonant effect. Songs commonly start with a descending whistle (barely audible at distance) and/or rattling sounds. Main call "chak-chak"; also mewing sounds.

Habitat. Tall humid forests, preferably primary forest. Found from *várzea* and gallery forest to lower montane forest (e.g. Sierra de Lema, in Venezuela). Rare in disturbed forest. Lowlands to 1100 m.



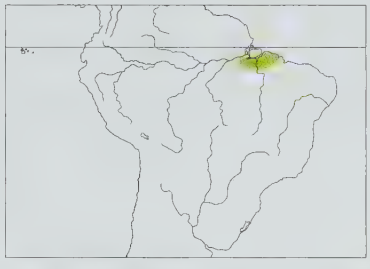
Food and Feeding. Insects and other arthropods; stomach contents from Suriname and Brazil include orthopterans (of family Tettigoniidae), bugs (Hemiptera), Coleoptera (of families Elateridae and Curculionidae), lepidopteran caterpillars, and spiders (Araneae). Consumes fruit and nectar, but no details available. Forages in groups, rather high in forest canopy.
Breeding. Season Feb–Apr in Venezuela and Suriname and Jul–Dec in Brazil (Amazonas). Probably moderately polygynous. Breeds in rather small colonies, usually with only 2–10 nests, well-spaced (not clustered); sometimes in mixed colonies with *P. decumanus* (Venezuela) or with *Cacicus haemorrhous* (Suriname and Brazil). Singing male may perform a deep bow, and may display while jumping into nests; displaying male also shakes wings, usually with no audible wing-flaps. Nest built by female, purse-shaped and open at top (shorter than that of *P. decumanus*, and lacks elongated pyriform shape), woven from diverse plant fibres such as roots, dark fungal rhizomorphs, epiphytes, strips of lianas, etc., and suspended from branch tip mostly 20–25 m above ground; prefers tall trees and may use same ones year after year, e.g. a mulateiro (*Peltogyne*) 25 m tall in Brazil (near Manaus) was used for nesting for at least three years. Clutch 2 eggs, greenish-white, marked purple-brown, dark brown and grey, mean dimensions 33·7 × 22·8 mm; incubation by female; male parental care probably limited to nest-guarding. No other information. Reported as a host of *Molothrus oryzivorus*.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Relatively abundant throughout most of Amazonia and the Guianan region; scarcer or local at edge of its range, e.g. in NE Venezuela (Sucre) and in S Amazonia. Rare in Bolivia, where there are very few records, all since year 2000; probably of only marginal occurrence in that country. Appears to be the most forest-adapted of the oropendolas, being sensitive to deforestation. Occurs in several protected areas, including, among others, Canaima National Park (Venezuela), Tuparro National Park (Colombia) and Tapajós National Park (Brazil).
Bibliography. Crandall (1940), Fraga (2004), Haverschmidt (1968, 1972b), Haverschmidt & Mees (1994), Hellmayr (1937), Hilty (2003), Hilty & Brown (1986), Jaramillo & Burke (1999), Oniki & Willis (1983), Price & Lanyon (2004a, 2004b), Restall *et al.* (2006), Ridgely & Tudor (1989), Schubart *et al.* (1965), Snethlage (1928a), Tobias & Seddon (2007).

20. Amazonian Oropendola

Psarocolius yuracares

French: Cassique bicolore **German**: Olivkopf-Stirnvogel **Spanish**: Cacique Amazónico
Other common names: Olive Oropendola

Taxonomy. *C.[assicus] yuracares* d'Orbigny and Lafresnaye, 1838, territory of the Yuracares (= Chapare), Cochabamba, Bolivia.
Sometimes placed in genus *Gymnostinops*. Often considered conspecific with *P. bifasciatus*, mainly because intermediate-looking individuals that are thought to be hybrids occur in area of range overlap in E Amazonian Brazil (Pará); no details of pairing behaviour or other aspects of natural history in contact zone are yet available, and further research required. Both species sometimes considered part of the group formed by *P. montezuma*, *P. guatimozinus* and *P. cassini*. Also, analysis of mitochondrial DNA indicates closer relationship of present species with *P. viridis* than with *P. decumanus*. Two subspecies currently recognized.
Subspecies and Distribution.
P. y. yuracares (d'Orbigny & Lafresnaye, 1838) – Amazon and upper Orinoco Basins from S Venezuela (W Bolívar) and Colombia (Meta and Guainía) S to E Ecuador, E Peru and C Bolivia (Santa Cruz), E to C Brazil (E to R Negro and R Tapajós).
P. y. neivae (E. Snethlage, 1925) – S Pará (between R Tapajós and R Tocantins) to N Goiás and Mato Grosso, in EC Brazil.



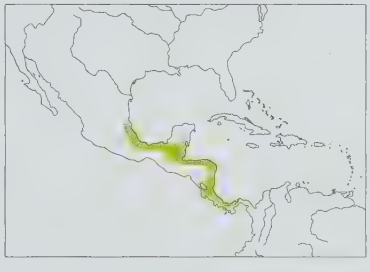
Descriptive notes. Male average 51 cm, 449·6 g; female average 42 cm, 259·2 g. Male nominate race has head to mantle and breast bright olive-green or olive-yellow (amount of yellow in colour varies individually, even within a single population), a few thin grey feathers forming small nuchal crest; bare pink facial patch; wing and rear parts of body bright chestnut; tail yellow, central pair of rectrices olive-green; iris dark brown; bill is expanded into casque, and is dark grey with reddish-orange tip; legs blackish. Female is smaller than male and without crest. Juvenile is duller than adult, and has much duller bare facial patch. Race *neivae* lacks yellow hue in foreparts, being darker olive, almost blackish, on head. Voice. Male song often a thin descending whistle, followed by a complex rattle with woody undertones, and ending in loud warble or a sustained note, with complex harmonics; song appears less variable than that those of congeners, even when geographically well-separated populations compared (e.g. Venezuela compared with Bolivia). Calls include soft "yok" and louder "awk".
Habitat. *Terra firme* forest, ranging into humid submontane forest; sometimes found in plantations and secondary growth. Nominate race up to 600 m.
Food and Feeding. Stomach contents from Brazil include insects, i.e. grasshoppers (Acrididae) and other orthopterans and lepidopteran larvae, also snails (Gastropoda) and fruit. Commonly drinks nectar of balsa flowers (*Ochroma*). Forages in trees at canopy level. In humid submontane forest in Chapare (C Bolivia) uses gaping to open mats of epiphytes and moss growing on trunks and main branches. In this region sometimes seen in mixed-species foraging flocks with other oropendolas, and with *Cacicus cela*.
Breeding. Season Jan–Apr in Venezuela and Aug–Nov in Bolivia. Polygynous. Colonial: in Venezuela (lower R Caura basin) two colonies held, respectively, two and four males and 14 and 17 nesting females, most nests packed into 3–4 thick clusters, with two or three relatively isolated nests, one tree used also by nesting *Cacicus haemorrhous*; in Bolivia two small colonies, one with six nests, also one large colony of 60 nests in two separate clusters, at least one displaying male at each cluster, this tree used also by *P. decumanus* and *Cacicus cela*. During display, male may perform a deep bow while singing. Nest built by female, a long purse suspended from branch tip, in Venezuela isolated *Erythrina* trees used for three consecutive years, in Bolivia *Socratea* palms emerging above canopy (the large colony in emergent tree near fruit orchards and farms). No other information.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common in most of range; rare and local in Venezuela and Ecuador. Has extensive distribution. Found in several protected areas, including, among others, Serrania de la Macarena National Park (Colombia), Jaú National Park (Brazil) and Madidi and Carrasco National Parks (Bolivia). Regarded as a pest by fruit-growers in Bolivia.
Bibliography. Fraga & Kreft (2007), Haffer (1974), Hilty & Brown (1986), Jaramillo & Burke (1999), McCarthy (2006), Price & Lanyon (2002b, 2004a, 2004b), Restall *et al.* (2006), Rodríguez-Ferraro (2006), Schubart *et al.* (1965), Snethlage (1925).

21. Para Oropendola

Psarocolius bifasciatus

French: Cassique du Para **German**: Parastirnvogel **Spanish**: Cacique de Pará
Other common names: Spix's Oropendola

Taxonomy. *Cassicus bifasciatus* Spix, 1824, Belém, Pará, Brazil.
Sometimes placed in genus *Gymnostinops*. Often considered conspecific with *P. yuracares*, mainly because intermediate-looking individuals that are thought to be hybrids occur in area of range overlap in Pará; no details of pairing behaviour or other aspects of natural history in contact zone are yet available, and further research required. Both are sometimes considered part of the species group formed by *P. montezuma*, *P. guatimozinus* and *P. cassini*. Monotypic.
Distribution. E Pará and W Maranhão (S of R Amazon and E of R Xingu), in E Amazonian Brazil.



Descriptive notes. Male 47–53 cm, 430 g; female 34·5–38 cm, 198 g. A large chestnut oropendola with a black hood. Male is mostly black, blending into rich chestnut on back, rump, wings, flanks and crissum; has a few elongated crown feathers, which form a smallish black crest; bare pink-coloured face patch; tail yellow, with central pair of rectrices black; iris brown; bill is expanded into swollen casque, and is black with orange-red tip; legs blackish. Female is rather similar to male, but overall is somewhat duller and lacks the crest. Juvenile undescribed. Voice. No information available.
Habitat. Inhabits tall humid forest and nearby plantations.
Food and Feeding. Little information available. Reported as feeding on cultivated fruits; probably omnivorous, as other large oropendolas.
Breeding. Season Feb. A colony of four nests observed in 1920 near San Antonio do Prata (Pará): nests looked like elongated bags more than 50 cm long, and were attached to tips of highest branches of a huge dead or leafless tree growing between forest and plantations. No further information.
Movements. Apparently resident.
Status and Conservation. Not assessed. Besides its relatively small range, this species seems rare and local; probably declining as a result of deforestation. Protected in a few reserves, such as Floresta de Caxiuana, in Pará; in Maranhão, the species could be protected if the proposed Gurupi Biological Reserve becomes properly established.
Bibliography. Haffer (1974), Jaramillo & Burke (1999), McCarthy (2006), Novaes & Lima (1998), Oren (1991), Price & Lanyon (2004a), Ridgely & Tudor (1989), Snethlage (1925, 1935b).

22. Montezuma Oropendola

Psarocolius montezuma

French: Cassique de Montezuma **Spanish**: Cacique de Moctezuma
German: Montezumastirnvogel
Other common names: Great Oropendola

Taxonomy. *Cacicus Montezuma* Lesson, 1831, Mexico.
Sometimes placed in genus *Gymnostinops*. Forms a species group with *P. guatimozinus* and *P. cassini*, and all three possibly conspecific; *P. bifasciatus* and *P. yuracares* sometimes considered part of same group. Monotypic.
Distribution. Atlantic slope of E Mexico from San Luis Potosí S to Quintana Roo, and Caribbean slope from Belize S to C Panama (Colón).

Descriptive notes. Male average 47·5 cm, 521 g; female average 39·2 cm, 246 g. The largest icterid, some males reaching 562 g. Has bare facial skin pale blue, conspicuous pink wattle at base of bill; head and upper breast black, rest of body deep dark chestnut; remiges chestnut with blackish tips; tail yellow, central pair of rectrices black; iris brown; bill is expanded into swollen casque, and is black with orange distal half; legs black. Sexes similar, female considerably smaller than male. Juvenile resembles adult, but duller in colour. Voice. Loud and impressive male song starts with low-pitched gurgles, grows to a remarkable crescendo in pitch and volume, with complex harmonics, and ends in a long note; individual and geographical variations occur. Alarm call mostly a repeated "krrak".
Habitat. Humid tropical forest, often in clearings and edges (particularly when breeding); also riparian forest along rivers and channels, second-growth forest, shady pastures, and plantations (bananas, cacao, etc.). To 1600 m.
Food and Feeding. Insects and other arthropods, also frogs and other small vertebrates; also much fruit, and nectar of large flowers e.g. balsa (*Ochroma pyramidale*). Vertebrates killed include fledgling Black-faced Grosbeak (*Caryothraustes poliogaster*) and chicks of Lance-tailed Manakins (*Chiroxiphia lanceolata*). Among native fruits taken are those of the trees *Bursera simaruba*, *Chrysophyllum mexicanum* and *Spondias mombin*, the palm *Thrinax radiata*, and even those of the herbaceous *Rivina humilis*; cultivated fruits eaten include bananas, akee (*Blighia sapida*), cacao, etc. In Mexico, five species of native tree germinated from collected excrement of this oropendola. Feeds mostly in trees, in upper level, rarely in lower strata or on the ground. Females, because of smaller size, may find food in smaller and thinner branches than those searched by males. When not breeding forms mixed-species foraging flocks with other icterids and jays, often with Brown Jays (*Psilorhinus morio*).
Breeding. Season Feb–Aug in Mexico (Quintana Roo) and Jan–Aug in Costa Rica. Mating system harem polygyny. Colonial breeder, 21–85 (average 57·5) nests per colony in Quintana Roo and 3–172 (average 31) nests per colony in Costa Rica, colonies located on one to few isolated trees,

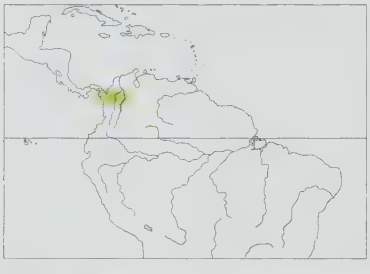
usually not in unbroken forest, clusters of thickly packed nests clearly visible within largest colonies; males around colony form linear hierarchy based on dominance during aggressive episodes, top-ranking or alpha male remains in colony for 52–68% of time, beta and next ranking males visit during temporary absences of alpha male; DNA-fingerprinting study of 21 chicks showed that alpha males sired 33% of chicks, beta males 19%, remaining chicks sired by lower-ranking males and those displaying away from colony. When displaying, breeding male performs a deep bow, and may even jump to the side of a nest. Nest built by female, taking 13–18 days, a purse 60–180 cm long, open at top, woven from rather coarse plant fibres, in Mexico mostly fibres from palm leaves (*Sabal*, *Cocos*), strips of banana leaves and *Cyperus*, bottom of nest lined with dry leaves (female commonly steals material from neighbouring nests), suspended from branch tip 13–33 m above ground; seems to prefer certain species of tree, among native ones *Ceiba pentandra*, *Cordia alliodora*, *Bursera simaruba*, *Brosimum alicastrum*, etc.; may build colony over river, channel or even road, or near buildings if unmolested. Clutch 2 eggs, white or buffish-white with blackish spots and scrawls, mean dimensions 39·4 × 25·4 mm; incubation by female, period 17–18 days; chicks fed by female, nestling period c. 35 days. Nests parasitized by *Molothrus oryzivorus*, the latter's eggs usually removed from nest by the host. Males may attack nest predators and brood parasites. Reported as rearing normally one chick in Costa Rica, the second nestling to hatch usually surviving for only a few days.

Movements. Apparently sedentary; possibly some local altitudinal movements in Costa Rica and Panama.

Status and Conservation. Not globally threatened. Locally common to uncommon. Tolerates, and may even prosper from, moderate deforestation. Found in many national parks and other protected areas.

Bibliography. Crandall (1914), Cunningham & Lewis (2006), Fraga (1986, 1989), Haffer (1974), Howell, S.N.G. & Webb (1995), Howell, T.R. (1964), Jaramillo & Burke (1999), Nava Solorio (1994), Price & Lanyon (2002b), Skutch (1954), Smithe (1966), Stiles & Skutch (1989), Webster (1994a, 1994b, 1994c, 1995, 1997), Webster & Robinson (1999), Wetmore *et al.* (1984), Wolf (1971).

23. **Black Oropendola**



Psarocolius guatimozinus

French: Cassique noir **German**: Mohrenstirnvogel **Spanish**: Cacique Negro

Taxonomy. *Ostinops guatimozinus* Bonaparte, 1853, Garrapata, River Magdalena, Antioquia, Colombia.

Sometimes placed in genus *Gymnostinops*. Forms a species group with *P. montezuma* and *P. cassini*, and all three possibly conspecific; *P. bifasciatus* and *P. yuracares* sometimes considered part of same group. Monotypic.

Distribution. E Panama (Panamá and Darién) and NW Colombia (Chocó, Antioquia and Caldas).

Descriptive notes. Male c. 47 cm, female c. 39 cm. Has bare facial skin pale blue, pink wattle at base of bill; otherwise mostly black, becoming dark chestnut on scapulars, upperwing-coverts, lower back to uppertail-coverts (except rearmost ones, black) and undertail-coverts; tail yellow, short central pair of rectrices black; thin crest of black feathers; iris brown; bill is expanded into swollen casque, and is black with orange tip; legs blackish. Sexes similar, female considerably smaller than male and with shorter crest. Juvenile undescribed. Voice. Male in display has loud song with low-pitched gurgles and high-pitched metallic notes; resembles that of *P. montezuma*, but sometimes lacks crescendo. Low "cruk" call described.

Habitat. Humid forest and forest edge, also nearby plantations; to 800 m.

Food and Feeding. Few details available on diet; presumably feeds on insects and other arthropods, small vertebrates, fruit, and nectar of large flowers. Forages at higher levels of forest. Seen to probe in flowers and to use open-bill gaping inside them. Singly and in small groups, rarely in larger groups.

Breeding. Season Feb in Panama and Apr–Jun in Colombia. Probably polygynous. Nests in colonies of up to at least 20 nests. Male gives deep bows while singing. Nest a long purse, open at top, lined with pieces of dry leaves, attached to branch tips. Clutch apparently 2 eggs, white or pinkish-white with blackish and brownish spots and scrawls, mean dimensions 34·6 × 24·8 mm. No further information.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Darién Lowlands EBA and Nechí Lowlands EBA. Uncommon to locally common. Range sufficiently extensive, and populations seem stable. Occurs in Darién National Park, in Panama.

Bibliography. Haffer (1974), Hardy *et al.* (1998), Hilty & Brown (1986), Jaramillo & Burke (1999), Price & Lanyon (2002b, 2004a), Restall *et al.* (2006), Ridgely & Tudor (1989), Wetmore *et al.* (1984).

24. **Baudo Oropendola**

Psarocolius cassini

French: Cassique de Cassin **German**: Braunmantel-Stirnvogel **Spanish**: Cacique de Cassin
Other common names: Chestnut-mantled Oropendola

Taxonomy. *Gymnostinops cassini* Richmond, 1898, Río Truandó, northern Chocó, Colombia.

Sometimes placed in genus *Gymnostinops*. Forms a species group with *P. montezuma* and *P. guatimozinus*, and all three possibly conspecific; *P. bifasciatus* and *P. yuracares* sometimes considered part of same group, and bare facial parts of present species resemble those of *P. bifasciatus*. Monotypic.

Distribution. Coastal lowlands and foothills of NW Colombia (Chocó and NW Antioquia).

Descriptive notes. Male 46 cm; female 39·5 cm. Has bare facial skin and malar wattle pink; otherwise hood and underparts mostly black, becoming rich chestnut on back, rump, wings, flanks and crissum; tail yellow, central pair of rectrices black; iris brown; bill is expanded into swollen casque, and is black with orange tip; legs blackish. Distinguished from *P. guatimozinus* (also present in NW Colombia) mainly by combination of pink (not blue) bare facial patch and chestnut wings, also by lack of crest. Sexes similar, female smaller and duller than male. Juvenile undescribed. Voice. Little known. Male song reported as similar to those of *P. guatimozinus* and *P. montezuma*.

Habitat. Limited information. Observed in lowland forests (primary and secondary) growing on sandy soil or along rivers, and with relatively open canopy; to 400 m in foothill forests. Possibly some preference for primary forest with naturally broken canopy, including very tall emergents, in which it has been seen to forage.

Food and Feeding. Few data. Diet includes fruit and insects, but no further details of diet. Seems to forage mostly in canopy, in groups of up to ten individuals. Reported in mixed-species foraging flocks with *P. wagleri*.

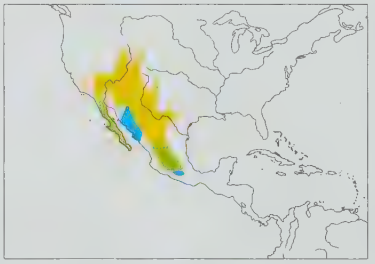
Breeding. Season at least Jan–Mar; one nesting colony observed in Mar 1991; another had 13 nests (7 inactive, 6 with nestlings) in Feb 2011. Nests at the 2011 colony were elongated purses of coarse fibres, suspended from fronds of unidentified palm. Colony visited by *Molothrus oryzivorus*. No further information.

Movements. Probably resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in Darién Lowlands EBA. Rare. Until very recently known from only five localities, including headwaters of R Acandí, where breeding colony had been recorded in 1991, and a site N of Ensenada de Utría National Park (near Pacific coast), where two individuals found in 1997 and six observed two years later. In 2010, during an expedition in W Andes, two groups, totalling 70–80 individuals, were discovered c. 120 km from Ensenada de Utría National Park, close to the only other site where a very few were thought to survive. These two newly discovered groups are not within a protected zone, and deforestation in the area is accelerating. Further surveys being conducted in order to determine the precise conservation actions required. Habitat alteration and destruction, increasing in W Colombia, are the most serious threats to this very rare species. Suggestions that it may occur in nearby areas of Panama need to be followed up.

Bibliography. Anon. (2010d), Butchart & Stattersfield (2004), Ellery (2011), Haffer (1974), Hilty & Brown (1986), Jaramillo & Burke (1999), Restall *et al.* (2006), Ridgely & Tudor (1989), Stattersfield & Capper (2000), Strewe (1999), Strewe & López-Lanús (2002).

PLATE 73 ➤



Genus *ICTERUS* Brisson, 1760

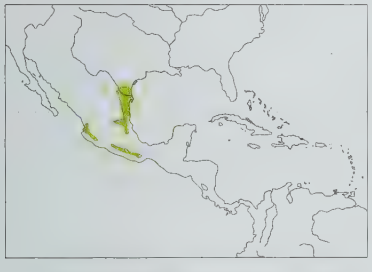
25. Scott's Oriole

Icterus parisorum

French: Oriole jaune-verdâtre **German**: Scott-Trupial **Spanish**: Turpial de Scott

Taxonomy. *Icterus Parisorum* Bonaparte, 1838, Mexico.
DNA data indicate that this species is closely related to *I. graduacauda* and *I. chrysater*. Monotypic.
Distribution. Breeds from SW USA (S California, Nevada, Utah, New Mexico and Texas) S to W & C Mexico (to S Baja California, Michoacán and Oaxaca); non-breeding range mostly in Mexico.
Descriptive notes. 19–22 cm; male average 34·7 g, female average 31·4 g. Male has head, breast and upperparts black, rump and uppertail-coverts yellow; upperwing black, pale yellow epaulet and white wingbars, narrow white edges of flight-feathers; tail black with yellow basal patches; belly to undertail-coverts yellow; iris dark brown; bill black, bluish-grey base of lower mandible; legs dark grey. Female has face and upper breast mottled yellowish and blackish, rest of head and upperparts olive, streaked dusky, becoming yellowish-olive on rump; upperwing as on male, but yellow less extensive; tail dark olive, edged yellowish-olive; underparts yellowish-olive; bare parts as for male. Immature resembles female. Voice. Song, by both sexes, rather long, with repetitions of short series of flute-like warbles, reminiscent of song of *Sturnella neglecta*. Female may sing when in or around nest. Call a nasal "cheh".

Habitat. Breeds in arid and semi-arid foothills and canyons with open woodland. Woodland types include pinyon–juniper (*Pinus–Juniperus*), oak scrub (*Quercus*), riparian woodland, groves of *Washingtonia* palms, and shrubs such as Joshua tree (*Yucca brevifolia*), other yuccas (e.g. *Yucca mohavensis*) and agaves (*Agave*); in parts of Mexico also in acacia (*Acacia*) and mesquite (*Prosopis*) woodland. Seldom seen in extreme, treeless deserts. To 3000 m; in S California at 300–2500 m.
Food and Feeding. Insects and other arthropods, small vertebrates, fruit and nectar. Insect prey include lepidopteran caterpillars, also grasshoppers and crickets (Orthoptera), and ants (Formicidae); rarely, feeds on wintering monarch butterflies (*Danaus plexippus*). Reported as eating small lizards. Takes native fruits, including those of several species of cactus; also visits orchards to feed on figs (*Ficus*) and peaches (*Prunus persica*). Visits flowers of native plants such as *Agave salmiana* and candlewood/ocotillo (*Fouquieria*), and also of cultivated ones, such as *Hibiscus*. Finds prey on low vegetation or on ground, and probes in clusters of dead leaves; com-



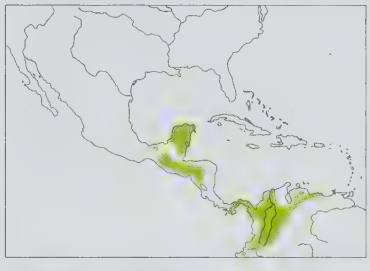
monly robs plants of nectar by piercing long corolla tubes. Found in pairs and in flocks of up to 20 individuals. May join mixed-species foraging flocks.
Breeding. Season Apr–May; reportedly double-brooded. Probably monogamous; pair-bond often maintained for entire breeding season, but only five of 24 pairs kept same mate in following season. Solitary breeder, territories reported as large, but few quantitative data; in USA (Texas) nests of neighbouring pairs 150–170 m apart. Nest built by female, a shallow bag or cup of plant fibres, commonly yucca fibres, lined with soft grass, hair, cotton or similar material, external diameter 10·5–13 cm, external depth 9 cm, frequently attached to older lower leaves of crown of yucca, and partially hidden among them, sometimes attached or supported by side branches (rather than suspended from rim as are most oriole nests); uses many species of tree, including, among others, sycamores (*Platanus*), oak, candlewood/ocotillo, palms, yuccas, junipers. Nests sometimes usurped by breeding House Finches (*Carpodacus mexicanus*). Clutch 2–4 eggs, pale blue with spots, blotches and lines in blackish, shades of brown and grey, mean dimensions 23·6 × 16·8 mm; incubation by female, period 14 days; chicks fed by both sexes, nestling period 14 days; both parents mob nest predators such as jays (Corvidae) and hawks (Accipitridae). Nests frequently parasitized by *Molothrus aeneus*. In a study of 85 nests, only 25% of eggs produced fledglings. Yearling males rarely mate and breed.
Movements. Medium-distance migrant, with little overlap between breeding and non-breeding ranges. Most winter in Mexico (from Baja California, Sinaloa and Coahuila S to Guerrero and Oaxaca). Autumn departure in USA from mid-Jul, spring arrival begins in late Mar; reported as migrating N in spring along coast of Baja California. Small numbers overwinter in S California and nearby Arizona. Also some altitudinal movement. Vagrants reported from many W states of USA, with a few records as far E as Louisiana, and recorded also in Ontario (Canada).
Status and Conservation. Not globally threatened. Uncommon to locally common. Annual censuses in USA reveal slight fluctuations in numbers. Tolerates moderate habitat modification, and frequently visits gardens and orchards. Found in several protected areas in USA and Mexico.
Bibliography. Bendire (1895), Bent (1958), Brower & Calvert (1985), Calvert *et al.* (1979), Cardiff & Remsen (1981b), Dixon (1960), Flood (2002), Howell & Webb (1995), Jaramillo & Burke (1999), Leck (1974), Lowther (1995), Miller & Stebbins (1964), Price *et al.* (2007), del Rio & Eguiarte (1987).

26. Audubon's Oriole

Icterus graduacauda

French: Oriole d'Audubon **German**: Schwarzkopftrupial **Spanish**: Turpial de Audubon
Other common names: Black-headed Oriole

Taxonomy. *Icterus graduacauda* Lesson, 1839, Mexico.
DNA data indicate that this species is closely related to *I. parisorum* and *I. chrysater*. Race *audubonii* intergrades with nominate. Proposed race *richardsoni*, described from Oaxaca (Chimalapa, in Tehuantepec), in S Mexico, synonymized with *dickeyae*. Four subspecies recognized.
Subspecies and Distribution.
I. g. audubonii Giraud, 1841 – extreme S USA (S Texas) and NE Mexico (Nuevo León and Tamaulipas).
I. g. graduacauda Lesson, 1839 – E Mexico (San Luis Potosí, S Tamaulipas and NW Veracruz).
I. g. nayaritensis van Rossem, 1938 – W Mexico (Nayarit and W Jalisco).
I. g. dickeyae van Rossem, 1938 – S Guerrero and Oaxaca (Sierra Madre), possibly also Chiapas, in S Mexico.



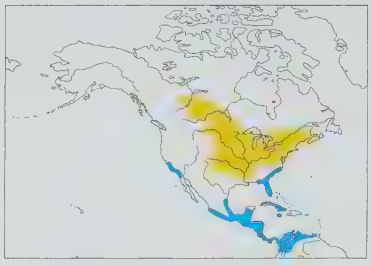
Descriptive notes. 21·5–24 cm; 31–52 g, male average 47 g, female average 45·7 g. Male nominate race has head to upper breast black, upperparts olivaceous yellow; upperwing and tail black, lesser and median wing-coverts yellow, flight-feathers narrowly edged white; belly to undertail-coverts lemon-yellow; iris dark brown; bill black, bluish-grey base of lower mandible; legs grey. Female is duller than male, more olive above, including nape and edges of tail. Juvenile has black of hood replaced with dull olive-green. Race *audubonii* differs from nominate mostly in larger size, also has tertials broadly edged white, greater wing-coverts tipped white (white wingbar); *nayaritensis* is more sexually dimorphic, with male brighter yellow and female duller olivaceous; *dickeyeae* has thicker bill than others, lacks olive tinge in back, and shows less white in wing. Voice. Song, by both sexes, a slow series of whistles and warbles, with rich harmonics, the notes rather pure and not varying much in pitch; said to resemble sound made by a boy learning to whistle. Alarm note a nasal "yee".
Habitat. Occupies many habitats, including humid evergreen forest, semi-deciduous forest, cloudforest, pine–oak (*Pinus–Quercus*) forests, gallery forest, and thorn-forest; also shady coffee plantations. In USA found in live oak (*Quercus virginiana*) forest, riparian forest and thickets, also in mesquite (*Prosopis*) woodland and scrub. Visits orchards, parks and gardens near its natural habitat. Usually found in denser vegetation than that preferred by other orioles. Up to 2500 m (*dickeyae*).
Food and Feeding. Insects and other arthropods, possibly small vertebrates, also seeds, fruits and nectar. Insects include adult and larval beetles (Coleoptera) and caterpillars (Lepidoptera). Wild fruits taken include hackberries (*Celtis*), beans of mesquite, and cactus fruits; cultivated fruits include peaches (*Prunus persica*), apples, plums, and loquat (*Eriobotrya japonica*). Takes sunflower seeds (*Helianthus*) from garden feeders. Forages in pairs; in non-breeding season may occur in groups of up to 8–10 individuals, also in mixed-species foraging flocks with other orioles, tanagers and jays (Corvidae). Regarded as shier, or more secretive, than other orioles.
Breeding. Season Apr–Jun in USA (Texas) and Apr–Sept in Mexico; probably two or three broods per season. Probably monogamous. Breeds as isolated territorial pairs during. Nest basket-shaped, built from palm fibres, grass and horsehair, relatively small, external diameter 8–10 cm, external depth 7–9·5 cm, placed at variable height, often among abundant twigs and leaves, and usually attached by rim and sides to small branches and twigs, sometimes supported by twigs below; in Texas commonly in mesquite, and nest trees in Mexico include *Liquidambar styraciflua*, cypress, *Ficus cotinifolia* and *Enterolobium cyclocarpum*. Clutch 3–5 eggs, bluish to greyish-white with spots and streaks in shades of brown, purple and blackish, mean dimensions 25·1 × 18 mm; incubation by female, no information on duration; chicks fed by both parents, nestling period 11–12 days; both sexes chase and mob cowbirds and potential nest predators. Nests parasitized by *Molothrus aeneus* and *Molothrus ater*; reported as rearing *Molothrus aeneus* chicks.
Movements. Apparently sedentary; probably some altitudinal movement in highlands.
Status and Conservation. Not globally threatened. Classified as "Rare" in the USA (Yellow WatchList priority species for conservation). Uncommon to rare in USA; uncommon to locally fairly common in Mexico. Estimated global population 200,000 individuals, of which great majority (at least 95%) in Mexico. Local populations along both sides of lower Rio Grande (Texas and Tamaulipas) have declined, and in many places disappeared, following clearing of woodland for irrigated agriculture; the species is now absent in Laguna Atacosa and Santa Ana National Wildlife Refuges. Habitat fragmentation, woodland clearance and urban development facilitate brood parasitism by cowbirds: parasitism by *Molothrus aeneus* may now be a relevant problem.
Bibliography. Bendire (1895), Bent (1958), Binford (1989), Flood (1990), Flood *et al.* (2002), Howell & Webb (1995), Jaramillo & Burke (1999), Lebbin *et al.* (2010), Lowther (1995), McCarthy (2006), Price *et al.* (2007), Rich *et al.* (2004).

27. Yellow-backed Oriole

Icterus chrysater

French: Oriole noir et or **German**: Schwarzflügeltrupial **Spanish**: Turpial Dorsidorado
Other common names: Lesson's Oriole; Honda Oriole ("*hondae*")

Taxonomy. *Xanthornus chrysater* Lesson, 1844, Mexico.
DNA data indicate that this species is closely related to *I. parisorum* and *I. graduacauda*. Hybridizes rarely with *I. mesomelas*. Proposed taxon *hondae* (based on two specimens from upper Magdalena Valley, in Colombia) appears undiagnosable; included within race *giraudii*. Three subspecies recognized.
Subspecies and Distribution.
I. c. mayensis van Rossem, 1938 – N Yucatán Peninsula (SE Mexico).
I. c. chrysater (Lesson, 1844) – C & S Yucatán Peninsula (S to Belize) and S Mexico (inland S Veracruz, extreme E Oaxaca and Chiapas) S to N Nicaragua.
I. c. giraudii Cassin, 1848 – C Panama (on both coasts) to NW Venezuela (Miranda), C & SW Colombia and extreme NW Ecuador (Esmeraldas).



Descriptive notes. c. 21–24 cm; male average 51·8 g, female average 48·7 g. Male nominate race is golden-yellow, with contrasting black forehead to throat and upper breast, and solidly black wing and tail; iris dark brown; bill black, bluish-grey base of lower mandible; legs grey. Female is similar to male but slightly duller, with olivaceous wash on crown and back. Juvenile lacks black on head and breast, and rest of plumage is duller than adult; immature olivaceous yellow, less contrasted, and with variable amount of black on head. Race *mayensis* is like nominate but smaller; *giraudii* is slightly smaller than nominate, black on face often more extensive, sexes alike in plumage. Voice. Song varies in length, in Panama 4–8 ascending and descending whistles, in Colombia 5–10 notes; in Santa Marta (N Colombia) said to have two parts, the first containing ascending whistles, the second repeated notes. Song quality varies from one location to another; at some sites reported as loud, rich and musical, at others as rambling, repetitive or monotonous. Common call "teea".
Habitat. Found in varied habitats, including native pine (*Pinus*) woodlands in Mexico, Belize and Nicaragua, montane oak (*Quercus*) woodland in Mexico, Guatemala and El Salvador, and dry thorn-woodland and scrub in N Yucatán (Mexico); in Panama occurs at edges of primary and secondary forest, and in N Colombia (Santa Marta) mostly in coffee plantations, clearings and cultivated land with patches of forest. Mostly 500–2500 m (nominate race) up to 2800 m (*giraudii*).
Food and Feeding. Insects, other arthropods, fruits and nectar. Insects in stomach contents from Panama included beetles (of families Cerambycidae and Curculionidae), cockroaches (Blattodea), ichneumon wasps (Ichneumonoidea), and many caterpillars (Lepidoptera); other arthropods included spiders (Araneae). Feeds on flowers of balsa trees (*Ochroma pyramidale*). Feeds on wild and cultivated fruits, including bananas. Feeds on fruits of native tree *Talisia olivaeformis* (Sapindaceae), using bill and legs to extract the inner pulp. In Panama takes nectar from forest-edge shrubs *Aphelandra sinclairiana* and *Heliconia*, in the first case removing by force and mandibulating the tubular corollas. Forages in pairs, in family groups and in small flocks of up to ten individuals; sometimes in mixed-species foraging flocks with jays (Corvidae).
Breeding. Season Feb–May in Panama, and egg-laying also in Jan in Colombia. Probably monogamous. Solitary breeder. One nest in Panama was a basket-like structure resembling that of *I. spurius*, made from dry grass, resistant but translucent, external diameter 11 cm, external depth 9–13 cm, suspended 7 m above ground from three points of forked branch of tree; other, undescribed nests were found in palms. Clutch 2–3 eggs, whitish with purplish-brown blotches and a few dark scrawls, mean dimensions 25·1 × 17·2 mm. Reported as host of *Molothrus bonariensis*. No further information available.
Movements. Appears resident; possibly some altitudinal movement by highland populations of nominate race.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Tolerates, and even thrives in, modified habitats; apparently invaded Santa Marta region of N Colombia following establishment of coffee cultivation. Found in several protected areas, such as Sian Ka'an Biosphere Reserve (Mexico) and Barro Colorado Nature Monument (Panama).
Bibliography. Howell, S.N.G. & Webb (1995), Howell, T.R. (1972), Jaramillo & Burke (1999), Leck (1974), McCarthy (2006), Miller (1947), Norton (1975), Olson (1983a), Price *et al.* (2007), Restall *et al.* (2006), Russell (1964), Stiles & Skutch (1989), Thurber *et al.* (1987), Wetmore *et al.* (1984), Willis & Eisenmann (1979).

28. Baltimore Oriole

Icterus galbula

French: Oriole de Baltimore **German**: Baltimoretrupial **Spanish**: Turpial de Baltimore
Other common names: Northern Oriole (when treated as conspecific with *I. bullockii*)

Taxonomy. *C.*[*oracias*] *Galbula* Linnaeus, 1758, America = Virginia, USA.
DNA data indicate that this is sister-species of *I. abeillei*. Formerly treated as conspecific with latter and with *I. bullockii*; hybridizes extensively with *I. bullockii* in a belt from S Canada (Alberta and Saskatchewan) S in Great Plains to S USA (Oklahoma and Texas), but assortative mating (or selection against hybrids) evident at several locations. Monotypic.
Distribution. Breeds in S Canada from NE British Columbia and Alberta E to S Ontario, S Quebec and Nova Scotia, S in C & E USA to C Texas, C Mississippi, NW Georgia, W Virginia and N Delaware; winters mostly in Florida, coastal California, Cuba and Jamaica, and Mexico S to N Colombia and Venezuela.

Descriptive notes. 18–22 cm; male average 34·3 g, female average 33·2 g. Male has head to upper back and to throat and upper breast black, lower back to uppertail-coverts and entire underparts below central breast bright orange; upperwing black, lesser and median coverts bright orange, greater coverts broadly tipped white, flight-feathers broadly edged white; tail black, outer rectrices terminally orange; in fresh (non-breeding) plumage has narrow orange feather tips on head and back, broader white wing edgings; iris dark brown; upper mandible black, blue-grey cutting edges, lower mandible blue-grey; legs dark grey to blue-grey. Female is variable in plumage, sometimes very like male, more often with olive-brown to orange-brown areas on head and upperparts, wing duller, lesser coverts brownish with dark centres, sometimes tinged yellow or orange, median coverts darkish at base, broadly tipped white (not orange), underparts duller, more orange-yellow; bare parts as for male. Juvenile is similar to dull female, but head and upperparts usually olive with orange tinge, throat and underparts light golden-orange, flanks olive. Voice. Song relatively short, a series of pleasing flute-like whistles, usually no more than 10 notes in total, mean duration less than 1·5 seconds; individually variable. Female sings rarely, song simpler than male's, sometimes in apparent duet with latter. Common calls include a chatter and an ascending whistle.

Habitat. Woodland edges, large clearings, orchards, parks and gardens; in non-breeding range found in wider variety of habitats, from canopy of humid forest to second growth, flowering trees in savanna, and coffee and cacao plantations. Sea-level to 3000 m.

Food and Feeding. Arthropods, and various plant items. Arthropods include insects, mainly Lepidoptera and their larvae (caterpillars), beetles (Coleoptera) and bugs (Hemiptera), and spiders (Araneae). Caterpillars represent 30% of total food, and include several spiny or hairy species in genera *Hyphantria*, *Euvanessa* and *Hemerocampa*; commonly preys on gregarious tent caterpillars (*Malacosoma*), which it extracts by tearing the webs. Plant food includes wild berries (e.g. *Rubus*, *Amelanchier*), cultivated fruits (grapes, cherries) and green peas. In non-breeding range feeds also on bananas, tomatoes and oranges, and punctures large fruits to obtain pulp and juice; in Panama feeds on fruits of *Bursera simaruba*; feeds on fruits of *Cecropia*, and takes nectar from flowering legume trees in genera *Erythrina*, *Inga* and *Calliandra*, also from the vine *Combretum fruticosum* and the epiphyte *Norantea*. Forages in trees and bushes; arthropod prey mostly gleaned from foliage of trees. On breeding grounds rarely social, foraging mostly as single individuals; on wintering grounds may forage in small groups, e.g. of up to 15 individuals in Costa Rica, at times in mixed-species foraging flocks. In winter often roosts communally.

Breeding. Season May–Jun; single-brooded. Monogamous; extra-pair copulations reported, but apparently rare. Solitary, nearest-neighbour distance usually 45–60 m, but nesting density may increase markedly during outbreaks of tent caterpillars; defends relatively small area around nest tree (feeding areas of neighbouring pairs commonly overlap), and defends nesting territory against both conspecifics and *I. bullockii*. Nest built mostly by female, a pouch 15–20 cm long and 8–9 cm wide (wider at bottom than at top), woven from plant fibres such as grass and stems (in cities and gardens, artificial materials such as string and plastic may be used), lined with soft materials such as seed plumes or feathers, attached to rather high branch, usually 5–22 m above ground, and concealed by foliage; generally in broadleaf tree such as cottonwood (*Populus*), elm (*Ulmus*), maple (*Acer*) or sycamore (*Platanus*), often isolated tree, at woodland edge, along channel or stream, or in urban park. Clutch 3–7 eggs, usually 4–5, pale greyish-white to bluish-white, streaked, blotched and scrawled with brown, mauve or black, mean dimensions 23·2 × 16 mm; incubation by female, period 12 days; chicks fed by both sexes, nestling period 12–14 days; male may feed incubating or brooding female, and both sexes defend nest. Rarely parasitized by *Molothrus ater*, as parents remove parasite's eggs from nest. Rarely, male breeds in first year.

Movements. Migratory. Leaves breeding grounds from Jul. Main migration route down Atlantic slope of Mexico. Some winter in coastal S California and North Carolina S to Florida (USA), but most migrate to S Mexico, Central America and NW South America (Colombia and Venezuela, rarely S to Ecuador); rare in Cuba, Bahamas and Jamaica, Sept–May. Very rare in Hispaniola and Puerto Rico, and accidental or vagrant S to Lesser Antilles and Cayman Is. Some individuals move N as far as New England, often taking advantage of bird feeders, but most apparently fail to survive the winter. Ringing data from Guatemala suggest that wintering orioles there were mostly transient, without fixed home ranges. Spring arrival on breeding grounds starts in April, and generally complete by late May. Vagrants recorded in Greenland, Iceland, Norway, British Is, Netherlands and Azores; up to end 2007, some 23 records from Britain and 2 from Ireland: most records in autumn, but species has overwintered and been recorded in spring.

Status and Conservation. Not globally threatened. Common to locally common; common in N & C parts of non-breeding range. Estimated global population 6,000,000 individuals. Able to live in modified environments.

Bibliography. cm 10

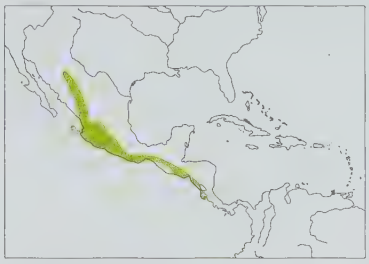
29. Black-backed Oriole

Icterus abeillei

French: Oriole d'Abeillé **German**: Schwarzmanteltrupial **Spanish**: Turpial Dorsinegro
Other common names: Abeille's Oriole

Taxonomy. *Xanthornus Abeillei* Lesson, 1839, Mexico.
Sometimes treated as conspecific with *I. bullockii*, but DNA data indicate that it is sister to *I. galbula*; all three formerly treated as conspecific. Monotypic.
Distribution. Breeds in C Mexico from Durango and Nuevo León S to Michoacán and Veracruz; winters in C Mexico mostly along transvolcanic belt S to Oaxaca.



Descriptive notes. 18–20·5 cm; 31–37 g. Male has crown to side of head, nape and upperparts black, orange supraloral line, narrow orange crescentic patch above and below eye (looking like spectacles); upperwing black, median and greater coverts white (forming large white patch), flight-feathers broadly edged white; tail black, outer three feather pairs yellow with black tip; chin and median throat stripe black, rest of throat and underparts orange-yellow, flanks and exterior of thighs black; iris dark brown; upper mandible black with grey cutting edges, lower mandible blue-grey; legs blue-grey. Female is much duller than male, with black areas, including wing and tail, replaced with olivaceous grey, and throat dull orange with white median stripe, breast dull orange, becoming greyish-white on belly and flanks. Juvenile resembles female, but duller, with less white in wing, and buffish below, with yellowish throat; immature male also like female, but has black throat stripe and lores, also darker feather centres above, and is brighter orange below. Voice. Song a rich warbie, often with some scratchy notes, covering rather wide frequency range, resembles that of *I. bullockii*. Calls include loud chatter and nasal "chay".
Habitat. Breeds in open forest, clearings and forest edge, riparian habitats, orchards and gardens; in winter also found in oak (*Quercus*) and pine (*Pinus*) montane forests, and in fir (*Abies*) forests. Breeds at 1500–3000 m, sometimes up to 3900 m; winters at similar elevations.
Food and Feeding. Insects, spiders (Araneae), fruits, nectar. One of main avian predators of the toxic monarch butterfly (*Danaus plexippus*) that winters in Mexico; feeds mostly on less toxic internal parts of the butterflies. Forages in pairs and small groups.
Breeding. Season Apr–Aug. No other published information.
Movements. Apparently a short-distance migrant within C Mexico.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population in range 50,000–500,000 individuals. Occurs in some protected areas, such as Pico de Orizaba National Park.
Bibliography. Arellano-Guillermo *et al.* (1993), Brower & Calvert (1985), Edwards (1972), Hardy *et al.* (1998), Howell & Webb (1995), Jaramillo & Burke (1999), Kondo *et al.* (2004), McCarthy (2006), Omland & Kondo (2006), Price *et al.* (2007), Rising (1970, 1973).

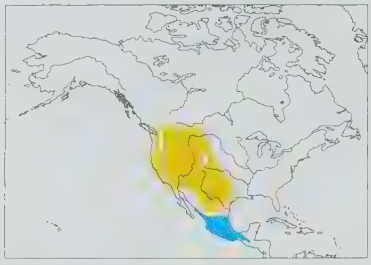
30. Streak-backed Oriole

Icterus pustulatus

French: Oriole à dos rayé **German**: Piroltrupial **Spanish**: Turpial Dorsilistado
Other common names: Scarlet-headed Oriole ("*pustulatus* group"); Tres Marias Oriole (*graysonii*); Sclater's Oriole ("*sclateri* group")

Taxonomy. *Ps.*[*arocolius*] *pustulatus* Wagler, 1829, Mexico.
DNA data indicate that present species is sister to *I. bullockii*. Races often divided into three groups, "*pustulatus* group" (nominate race and *microstictus*) in N of range, single-species "*graysonii* group" on Tres Marias Is (off WC Mexico) and "*sclateri* group" (*formosus*, *maximus*, *alticola*, *sclateri* and *pustuloides*) in S of range. Groups sometimes thought to represent three distinct species, but mitochondrial-DNA divergence among mainland races slight; on other hand, insular *graysonii*, isolated for longer time, may warrant treatment as a full species, but scant information available on its behaviour and breeding biology. In Mexico, birds from S Sinaloa S to S Nayarit sometimes placed in separate race *yaegeri*, those from SW Jalisco S to S Guerrero in *dickermani*, and birds in interior C & S Mexico in *interior*, but diagnostic characters of these uncertain. Other proposed races are *flammulatus* (described from Monte Redondo, in Honduras), subsumed in *alticola*, and *connectens* (interior El Salvador), which is intermediate between *alticola* and *sclateri* and is merged with latter. Eight subspecies currently recognized.
Subspecies and Distribution.
I. p. microstictus Griscom, 1934 – W Mexico from Sonora and W Chihuahua S to Jalisco.
I. p. graysonii Cassin, 1867 – Tres Marias Is, off W coast of Mexico (Nayarit).
I. p. pustulatus (Wagler, 1829) – S Mexico from Colima S to Puebla, W Veracruz and N Oaxaca.
I. p. formosus Lawrence, 1872 – S Mexico (S Oaxaca and Chiapas) S to NW Guatemala.
I. p. maximus Griscom, 1930 – R Negro valley, in NC Guatemala.
I. p. alticola W. deW. Miller & Griscom, 1925 – Guatemala and W Honduras.
I. p. sclateri Cassin, 1867 – Pacific coast from El Salvador S to NW Costa Rica.
I. p. pustuloides van Rossem, 1927 – Volcán San Miguel, in EC El Salvador.
Descriptive notes. 19–21 cm; male average 43·1 g, female average 34·6 g; sexes combined 31·8–41·6 g (*microstictus*), 29–39·4 g (*graysonii*), male average 57 g (*alticola* and *sclateri*). Male nominate race has head and chest deep orange, contrasting black lores and chin to upper breast; upperparts orange, rather heavy black streaks on mantle and back; tail black, feathers with whitish tips, outer edge of outermost rectrix white; lesser upperwing-coverts orange, rest of upperwing black, median coverts broadly tipped white (prominent wingbar), greater coverts edged and tipped whitish (pale panel), flight-feathers edged whitish; underparts orange to orange-yellow; iris dark brown; bill black, basal half of lower mandible bluish-grey; legs bluish-grey. Female is similar to male, but slightly less richly coloured. Juvenile resembles dull female, but no black on lores and chin to breast, has crown olive-tinged, back greyer and almost unstreaked, less white in wing, dirty yellowish below; immature similar to female. Races differ mainly in intensity of bright coloration, amount of streaking on back, and size: *microstictus* is like nominate, but brighter, head and chest orange-yellow to fiery orange-red, black streaks above smaller, female sometimes duller and greener than male; *graysonii* has orange-yellow head, fewer black streaks on back; *alticola* has orange-yellow head, back so heavily streaked as to look solidly black; *sclateri* resembles previous in having orange-yellow head, but back is evenly streaked black and yellow; *formosus* resembles last, but smaller, and streaks above are in form of tear-shaped black spots; *maximus* is similar to *alticola*, but paler, more yellow than orange-yellow; *pustuloides* differs from nearby populations (*sclateri*) in smaller size and deep orange head. Voice. Song, by both sexes, mostly a melodic warbled series of whistles, somewhat like that of a vireo (Vireonidae), sometimes including dissonant "churr" notes; females usually sing less frequently than males. Common calls include chatters and a sharp "chit".

Habitat. Occupies canopy and edges of deciduous forest, swamps with palo verde (*Parkinsonia aculeata*) shrubs, thorny woodland and scrub, savannas, and trees at roadsides and villages. Occurs from lowlands up to c. 500 m; races *maximus* and *alticola* also range higher, locally reaching up to 2000 m. In El Salvador, *pustuloides* lives in xeric woodland at 800–1000 m, sometimes in nearby lowlands.
Food and Feeding. Insects and other arthropods, also nectar and fruits. Two stomachs from El Salvador contained only insects. Gleans insects from foliage, and extracts larvae of beetles (Coleoptera) from rotten wood. Feeds on several fruits and arils of native plants. Takes nectar from flowers of the trees *Erythrina breviflora*, *Erythrina oliviae* and *Pseudobombax ellipticum* in Mexico, also from brush-like inflorescences of the vine *Combretum fruticosum* (individuals captured near the vine had pollen in plumage). Also catches bees (Apoidea) near flowers. Forages mostly in pairs and in family parties, occasionally in larger groups.
Breeding. Season May–Jul, later in N and at higher elevations. Probably largely monogamous; polygyny recorded. Solitary breeder. Nest a pensile bag 25–50 cm long, sometimes longer (to 70 cm), made from plant fibres and fungal rhizomorphs (reported as stealing nesting material from unguarded nests of conspecifics, and behaviour reciprocated by latter), placed rather high up in bush or tree, sometimes suspended from power line; often in thorny tree, including acacia (*Acacia*) species that harbour aggressive stinging ants (Formicidae), and reported also as nesting near wasp (Vespidae) nests; may nest in same tree with other orioles (mostly *I. gularis*, also *I. pectoralis*) and diverse birds, e.g. Rose-throated Becard (*Pachyramphus aglaiae*) and *Campylorhynchus* wrens. Clutch 3–4 eggs, rarely 5, white to pale blue with dark brown lines and blotches, mean dimensions 26 × 17·4 mm; incubation period 12–14 days; chicks fed by both sexes, nestling period c. 14 days. Nests are regularly parasitized by *Molothrus aeneus*, e.g. two of eleven nests in Oaxaca were parasitized; adults of present species have been reported feeding fledgling of *Molothrus oryzivorus* in Nicaragua.
Movements. Apparently resident; in 1930s, race *sclateri* reported as making some local movements. Rare visitor in SW USA (Arizona, California).
Status and Conservation. Not globally threatened. Fairly common to common; locally rather abundant. Race *microstictus*, recorded very occasionally in SW USA, bred in Arizona in 1993 and subsequently in some years. The insular Tres Marías population (*graysonii*) deserves protection, because of its tiny global range and its distinctiveness.
Bibliography. Bent (1958), Cortés-Rodríguez *et al.* (2008), Cruden & Toledo (1977), Dickerman (2007), Dickey & van Rossem (1938), Eguiarte *et al.* (1987), Gómez (1983), Gryj *et al.* (1990), Janzen (1971), Jaramillo & Burke (1999), Kaufman (1983), Lowther (1995), McCrary & Gates (2007), Phillips (1995), Price *et al.* (2008), Rowley (1984), Stiles & Skutch (1989), Toledo & Hernández (1979).



31. Bullock's Oriole

Icterus bullockii

French: Oriole de Bullock **German**: Bullocktrupial **Spanish**: Turpial de Bullock
Other common names: Northern Oriole (when lumped with *I. galbula*)

Taxonomy. *Xanthornus Bullockii* Swainson, 1827, "Table land" [of Mexico] = Temascáltepec, México State, Mexico.
DNA data indicate that present species is sister to *I. pustulatus*. In the past usually treated as conspecific with *I. galbula* and *I. abeillei*. Hybridizes extensively with former in a belt from S Canada (Alberta and Saskatchewan) S in Great Plains to S USA (Oklahoma and Texas), but assortative mating (or selection against hybrids) evident at several locations. Smaller race *parvus* possibly not worthy of recognition, and size difference within species apparently clinal; retained pending further study. Proposed race *eleutherus* (from N Texas, in S USA), supposedly more orange than nominate, considered to fall within range of variation of latter. Two subspecies tentatively recognized.
Subspecies and Distribution.
I. b. bullockii (Swainson, 1827) – breeds SW Canada (from S British Columbia, S Alberta and SW Saskatchewan) S in W USA (except C California S to W Arizona) to N Mexico (Sonora, Chihuahua and Coahuila); winters C Mexico S to C Guatemala.
I. b. parvus van Rossem, 1945 – breeds SW USA (from C California, S Nevada and W Arizona) S to NW Mexico (extreme N Baja California and extreme NW Sonora); winter range uncertain.
Descriptive notes. 19–23 cm; male average 37·9 g, female average 37·8 g. Male nominate race has crown to nape and back black, black eyeline and thin black stripe from chin to upper breast; rest of head, lower back to uppertail-coverts and entire underbody orange; upperwing black, median and greater coverts mostly white (prominent wingpanel), flight-feathers broadly edged white; tail black, outer rectrices orange with black tips; in fresh (non-breeding) plumage has narrow greyish feather tips on head and back, whitish tips below, broader white wing edgings; iris dark brown; bill bluish-grey, black culmen; legs bluish-grey. Female considerably duller than male, has head and facial markings olivaceous, head and upper breast duller yellow-orange, belly greyish-white; back and

On following pages: 32. Jamaican Oriole (*Icterus leucopteryx*); 33. Orange Oriole (*Icterus auratus*); 34. Yellow Oriole (*Icterus nigrogularis*); 35. Altamira Oriole (*Icterus gularis*); 36. Yellow-tailed Oriole (*Icterus mesomelas*); 37. Spot-breasted Oriole (*Icterus pectoralis*); 38. White-edged Oriole (*Icterus graceannae*); 39. Venezuelan Troupial (*Icterus icterus*); 40. Campo Troupial (*Icterus jamacaii*); 41. Orange-backed Troupial (*Icterus croconotus*).

wings paler and greyer, lacks striking white wingpanel, instead has white wingbar formed by broad tips of median coverts, sometimes with a faint second white wingbar formed by narrow tips of greater coverts; tail olivaceous, tinged orange; some birds with black on throat. Juvenile similar to female; young male acquires adult plumage through intermediate stages. Race *parvus* is smaller than nominate but otherwise similar. VOICE. Song, by both sexes, a short series of whistles, less musical than song of *I. galbula*, sometimes with notes repeated 2–5 times in a row. Calls include clicks, harsh "chuck" sounds and a short rattle.

Habitat. Open deciduous woodland with cottonwoods (*Populus*) and sycamores (*Platanus*), often in riparian habitat; open oak (*Quercus*) woodland in California, xeric mesquite (*Prosopis*) woodland, farms and ranches. Prefers areas with large trees mixed with grassland and herbaceous plants. Sea-level to at least 3000 m.

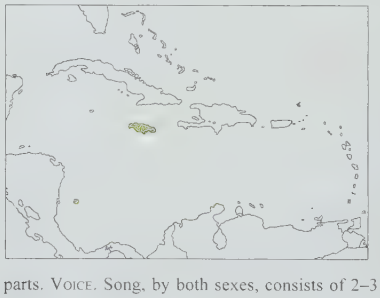
Food and Feeding. Omnivorous; stomach contents 79% animal matter, 21% vegetable. Insects include caterpillars of Lepidoptera, ants (Formicidae), weevils (Curculionidae), stink-bugs (Pentatomidae) and scale insects (Coccoidea); black olive scales (*Saissetia oleae*) found in 45 stomachs, amounting to 5% of food. Preys also on spiders (Araneae), and rarely on small lizards. Feeds on small fruits such as juneberries (*Amelanchier*), blackberries and raspberries (*Rubus*), elderberries (*Sambucus*), also some cultivated fruits. Takes nectar from flowers of the trees *Erythrina breviflora* and *Pseudobombax ellipticum* in Mexico (is a secondary pollinator of latter species); in California visits flowers of introduced eucalypts (*Eucalyptus*). Hunts for insects by gleaning in foliage; also picks insects from spider webs. Often forages in flocks of up to 20 individuals, even during breeding season.

Breeding. Season Apr–Jun, earlier in S of range; single-brooded. Mostly monogamous, in California study only two of 96 males were bigamous; pair-bond generally lasts for only one breeding season. Nests solitarily or in small loose colonies, in latter case with density of 15–18 nests/ha. Territorial behaviour variable; at low food density only nest-site defended, and female may forage up to 1 km from site. Nest built mostly by female, a pendent pouch c. 10 cm in length, woven from horsehair, plant fibres and grass, lined with wool or feathers, attached to a few thin branches, or more rarely to larger branch, commonly 3–8 m above ground, and usually not far from water in isolated tree, at woodland edge, in shelter-belt, or in farm or ranch; many trees used for nesting, including exotic eucalypt and native mesquite; colonies in California sometimes located near nests of Yellow-billed Magpies (*Pica nuttalli*), which provide some protection against predators. Clutch 3–7 eggs, usually 4–5, pale bluish to greyish-white, finely spotted and scrawled in shades of brown, mean dimensions 23·6 × 16·2 mm; incubation by female, period c. 12 days; chicks fed by both parents, nestling period 14 days; both sexes defend nest; in parts of W USA (Washington and California) fledglings may join groups, or crèches, of up to 100 individuals, attended by several adults. Nests parasitized by the cowbirds *Molothrus ater* and *Molothrus aeneus*; in experimental study, this icterid removed most cowbird eggs from its nests. In SW USA (California), 191 nests produced average of 2·67 fledged chicks, giving success rate of 53·4%. Rarely, males in California breed in first year.

Movements. Short-distance to medium-distance migrant. Nominate race leaves breeding grounds in Jul–Aug, many probably moving initially SW to moult, before continuing to Mexico, where arrival in S mainly Sept–Oct. Return migration begins in late winter; reaches S parts of breeding range from mid-Mar, but in N does not arrive until early to middle part of May, some not until Jun, females generally 1–2 weeks later than males. Scattered records of nominate race, mainly in autumn and winter, from as far E as Atlantic seaboard of Canada and USA, and also from Gulf Coast states; at least some of these, however, possibly referable to *I. galbula* (formerly treated as conspecific). Non-breeding grounds of race *parvus* not known; believed to lie in S part of breeding range and possibly farther S in NW Mexico.

Status and Conservation. Not globally threatened. Common or fairly common in most of range. Estimated global population of 3,800,000 individuals, and occurs in modified habitats. This species' consumption of the scale insect *Saissetia oleae*, a pest of citrus trees as well as olives (*Olea*), could make it beneficial to agriculture.

Bibliography. Bendire (1895), Bent (1958), Butcher (1991), Butcher & Rowher (1988), Carling *et al.* (2011), Cruden & Toledo (1977), Dixon (1989), Edinger (1988), Eguiarte *et al.* (1987), Howell & Webb (1995), Jaramillo & Burke (1999), Lee Cinty & Birch (1998), Lowther (1995), McCarthy (2006), Miller (1931), Misra & Short (1974), Omland *et al.* (1999), Richardson & Bolen (1999), Richardson & Burke (1999, 2001), Rising (1973, 1983, 1996b), Rising & Williams (1999), Rohwer & Johnson (1992), Rohwer & Manning (1990), Rohwer *et al.* (1989), Rothstein (1977), Sibley & Short (1964), Williams (1982).



32. **Jamaican Oriole**

Icterus leucopteryx

French: Oriole de Jamaïque **German**: Jamaikatrupial **Spanish**: Turpial Jamaicano

Taxonomy. *Ps.* [*arocolius*] *Leucopteryx* Wagler, 1827, Jamaica.
Appears not closely related to other Caribbean members of genus. Race *bairdi* of Cayman Is apparently extinct. Two extant subspecies recognized.

Subspecies and Distribution.
I. l. leucopteryx (Wagler, 1827) – Jamaica.
I. l. lawrencii Cory, 1887 – San Andrés I (E of Nicaragua).

Descriptive notes. 21 cm; c. 34–42 g. Male nominate race is mostly olivaceous yellow, brighter and yellower on belly, with black mask and throat to upper breast; upperwing black, coverts contrastingly white (striking wing patch), inner remiges (including tertials) broadly edged white; tail black; iris dark brown; bill bluish-grey, black culmen; legs dark grey. Female is similar to male, perhaps slightly duller. Immature is dull olivaceous green, with reduced black areas on head, more black on wings, and tail dusky green. Race *lawrencii* is brighter than nominate, more yellow-green, becoming lemon-yellow on underparts. VOICE. Song, by both sexes, consists of 2–3 musical, modulated whistles, e.g. "tie-tiewu", "tie-tiewu-tiewu" and similar (often transliterated as "Auntie Katie"), in rapid succession. Call a single or 2-note whistle, also a short chatter.

Habitat. Most types of forest and woodland in Jamaica, from coast to mountains, but rarely in mangroves. Also visits gardens. Sea-level to tops of mountains; mostly in lowlands.

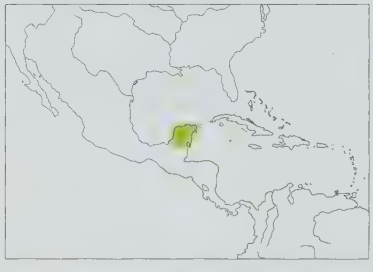
Food and Feeding. Insects, other arthropods, possibly small vertebrates, also nectar and fruit. Reported as feeding on fruits of seven species of native plant in genera *Trophis*, *Guapira*, *Clusia*, *Pithecellobium*, *Miconia*, *Bursera* and *Trichilia*; cultivated fruits taken include papayas, oranges and bananas, and particularly annonas (*Annona*). Takes nectar from introduced *Erythrina*; also visits hummingbird (Trochilidae) feeders. Often finds arthropods by removing pieces of bark with the bill to expose hidden items, an unusual habit among orioles; also searches in epiphytic bromeliads. Uses pecking and gaping techniques to extract fruit pulp. Forages in pairs and in family groups.

Breeding. Season Mar–Aug. Probably monogamous. Solitary breeder. Nest built by both sexes, a pouch woven from fibres taken from palm leaves, also with black fungal rhizomorphs, horsehair, and pieces of epiphytic Spanish moss (*Tillandsia usneoides*), suspended from branch fork or between two parallel twigs (unlike nests of Caribbean congeners, not stitched to leaves). Clutch 3–5 eggs, white with sparse dark brown marks, mean dimensions 24·5 × 16·8 mm; chicks fed by both sexes. Reported as a host of invading *Molothrus bonariensis*. No further information.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA and in San Andrés Island and Cayman Islands Secondary Areas. Common in Jamaica; abundant on San Andrés. Cayman Is race *bairdi*, restricted to Grand Cayman, last reported in 1967 and believed now extinct, reasons for its demise being unknown; this icterid, smaller and brighter yellow-green than nominate race, inhabited town gardens, as well as woodland.

Bibliography. Bradley (1995), Brown & Degia (1994), Gosse (1847), Hardy *et al.* (1998), Hilty & Brown (1986), Jaramillo & Burke (1999), Lack (1976), Omland *et al.* (1999), Price *et al.* (2007), Raffaele *et al.* (1998).



33. **Orange Oriole**

Icterus auratus

French: Oriole orange **German**: Goldtrupial **Spanish**: Turpial Yucateco

Taxonomy. *Ict.*[*erus*] *auratus* Bonaparte, 1850, Mérida, north Yucatán, Mexico.
According to DNA data, this species' closest relatives are *I. nigrogularis* and *I. leucopteryx*. Monotypic.

Distribution. SE Mexico (Yucatán Peninsula S to SC Campeche) and NE Belize; also Mujeres I, off NE Quintana Roo.

Descriptive notes. 19–21 cm; 26·7–36·1 g, one female 27 g. A small, slender oriole. Male has black lores and black median throat stripe extending to upper breast; rest of head bright orange, body orange-yellow above and below; scapulars black, tipped orange, upperwing black, lesser coverts orange, median coverts white, greater coverts tipped white, secondaries and tertials edged white, primaries edged white at bases (forming small white patch); tail black, indistinct greyish tip; iris dark brown; bill straight, black, basal half of lower mandible bluish-grey; legs bluish-grey. Female is duller than male, orange-yellow with olive wash, and sometimes streaked on back. Immature is like female, but more washed with olive, and with tail olive, not black. VOICE. Song a slow series of alternating ascending and descending whistles; also a fast "chuchuchuchu". Common call a nasal "nyeek".

Habitat. Seasonally deciduous forest, mesic to arid woodland and scrub, second growth, abandoned farmland; mostly in lowlands.

Food and Feeding. Not much information. Diet presumably insects and other arthropods, fruits and nectar. Commonly feeds on fruits of native tree *Talisia olivaeformis* (Sapindaceae), less frequently on fruits of medicinal tree *Metopium brownie* (Anacardiaceae). Task of obtaining *Talisia* fruit requires use of bill and legs to extract inner pulp from harder shell. Forages singly and in pairs; often with other orioles.

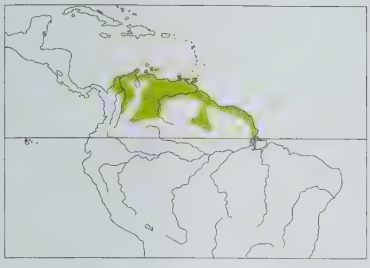
Breeding. Season Jul; one colony was asynchronous, some pairs building nests while others feeding fledglings. In Quintana Roo both solitary and colonial nester; colonies of 20–35 nests, up to five nests in one tree; in one colony there were also single nests of *I. cucullatus* and *I. prosthemelas*, and nests of Black Catbirds (*Melanoptila glabrirostris*). Nest a pouch 7·5 cm in external diameter and 12·5 cm in external depth, woven from blackish or yellowish fibres, attached to slender branches 1–9 m above ground in shrub or tree located in flooded scrub, or near *cenotes* (natural water-holes or ponds in limestone). No further information.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Common to fairly common. Found in Sian Ka'an and Calakmul Biosphere Reserves, in Mexico, and commonly seen around protected Maya ruins.

Bibliography. Howell & Webb (1995), Howell *et al.* (1992), Jaramillo & Burke (1999), Kantak (1979), Omland *et al.* (1999), Price *et al.* (2007).

34. **Yellow Oriole**



Icterus nigrogularis

French: Oriole jaune **German**: Orangebrusttrupial **Spanish**: Turpial Amarillo

Taxonomy. *Xanthornus nigrogularis* Hahn, 1819, north Brazil.
Four subspecies recognized.

Subspecies and Distribution.
I. n. nigrogularis (Hahn, 1819) – NW & NE Colombia (Caribbean region S to middle Magdalena Valley, and in Meta and Vichada), Venezuela (from Zulia E, mostly N of R Orinoco, to Delta Amacuro), Guyana, Suriname and French Guiana, and N Brazil (Roraima and Amapá).
I. n. curasoensis Ridgway, 1884 – Netherlands Antilles (Aruba, Curaçao and Bonaire).
I. n. helioeides A. H. Clark, 1902 – Margarita I, off N Venezuela.
I. n. trinitatis E. J. O. Hartert, 1913 – Trinidad, and nearby NE Venezuela (Paria Peninsula).

Descriptive notes. 20–21 cm; male average 39·5 g, female average 37·4 g (Suriname). Male nominate race has black area around eye and lores (mask) and in narrow band from chin to upper breast (bib); remainder of head and body bright orange-yellow; wing and tail black, lesser and median

wing-coverts yellow, greater coverts tipped white, primaries edged white basally, inner secondaries and tertials edged white; iris dark brown; bill black, blue-grey at base of lower mandible; legs grey. Female is similar to male, but with olivaceous tinge in yellow areas of plumage. Juvenile is duller and greenish, lacking black mask and bib, and with greenish tail. Races differ mainly in size, bill size and plumage coloration: *curasoensis* is paler yellow overall than nominate, with more white in wing, longer bill; *helioeides* is larger and stronger-billed than nominate, plumage more orange-tinged, has most white in wing; *trinitatis* resembles previous, but bill on average smaller, and has least white in wing (lacking on primaries). Voice. Song relatively soft, consists of repeated flute-like notes mixed with buzzes and harsher notes. Mimicry of other birds reported. Alarm call "chet-chet-chet".

Habitat. In Caribbean region mostly in arid to semi-arid woodland and scrub, with cacti, mesquite (*Prosopis*) and acacia (*Acacia*); in seasonally dry Llanos del Orinoco of interior Colombia and Venezuela frequents open woodland and edges of gallery forest; in Trinidad avoids unbroken forest and dry savannas. In Suriname found mostly in mangroves. Also cultivated land with trees and shrubs, riparian habitat, parks and gardens in towns. Lowlands below 800 m, but reported at up to 1800 m.

Food and Feeding. Stomach contents of 14 birds from Netherlands Antilles all included animal matter, and in eight cases also vegetal matter. Insects were mostly small beetles (Coleoptera), flies (Diptera), lepidopteran caterpillars, with some cicadas (Cicadidae) and grasshoppers (Orthoptera); other arthropods were spiders (Araneae) and wind scorpions (Solifugae). Feeds also on fruits of Barbados cherry (*Malphigia punicifolia*) and date palms (*Phoenix dactylifera*). Takes nectar from flowers of the trees *Erythrina fusca* and *Pithecellobium saman*. Usually in pairs or small groups.

Breeding. Season Jan–Aug in Trinidad, Feb–Aug in Suriname, and May–Sept in *llanos* of Venezuela. Apparently monogamous and territorial. Solitary nester. Nest a pendent pouch 25–50 cm long, 11 cm in diameter at bottom, woven from diverse plant fibres, mostly grass and palm fibres (colour of nest varies from greyish-brown to reddish-brown), sometimes fragments of plastic or paper, or string, incorporated, nest walls thicker at bottom, which contains lining of softer materials; attached to tree or shrub branch, often high in tamarind (*Tamarindus indica*) in Netherlands Antilles, or to *Avicennia* mangrove elsewhere; reported as nesting also in coconut palm (*Cocos nucifera*); may build close to older, disused nests; in Venezuela may nest close to aggressive birds, such as Great Kiskadee (*Pitangus sulphuratus*) or colonies of *Cacicus cela*. Nests usurped by Piratic Flycatcher (*Legatus leucophaius*) in Trinidad, possibly also in Venezuela. Clutch usually 2–3 eggs, in Santa Marta region of Colombia ten nests had 3 eggs, six held 2 eggs, and one 5 eggs (perhaps from two females), greenish-white or creamy white with sparse spotting and blotching in brownish, mauve and black, mean dimensions 24·6 × 16·6 mm (ten eggs from Trinidad average 27·1 × 17·9 mm); no information on incubation and nestling periods and on roles of sexes in parental care. Nests parasitized by *Molothrus bonariensis* in Trinidad.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Common throughout most of range. Very abundant in N Venezuela and on nearby islands; also numerous in parts of Netherlands Antilles, but rare on Bonaire.

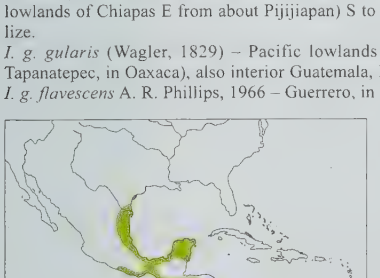
Bibliography. Allen (1905), Belcher & Smooker (1937), Cherrie (1916), Cruz & Andrews (1989), Haverschmidt (1951, 1968), Haverschmidt & Mees (1994), Hilty (2003), Jaramillo & Burke (1999), Losada-Prado *et al.* (2004), Manolis (1982), Price *et al.* (2007), Ridgely & Tudor (1989), Rutkis (1972), Todd & Carriker (1922), Voous (1983).

35. Altamira Oriole

Icterus gularis

French: Oriole à gros bec **German**: Schwarzkehltrupial **Spanish**: Turpial de Altamira
Other common names: Lichtenstein's/Black-throated Oriole

Taxonomy. *Ps.*[*arocolius*] *gularis* Wagler, 1829, Tehuantepec, Oaxaca, Mexico.



Following recent revision, several proposed races now considered to be based on age differences in plumage and other features: thus, *tamaulipensis*, described from Alta Mira (Tamaulipas), in E Mexico, *yucatanensis*, from Yucatán Peninsula, and *troglodytes*, from San Felipe (Retalhuleu), on Pacific slope of Guatemala, all subsumed in *mentalis*; and *gigas*, from Sacapulas (valley of R Negro), in C Guatemala, and *xerophilus*, from Progreso (Motagua Valley), in SW Guatemala, both synonymized with nominate. Three subspecies currently recognized.

Subspecies and Distribution.

I. g. mentalis Lesson, 1831 – extreme S USA (lower Rio Grande Valley, in Texas) and E & S Mexico (to Yucatán Peninsula, across Isthmus of Tehuantepec to Matias Romero area, also Pacific lowlands of Chiapas E from about Pijijiapan) S to Guatemala (to La Avellana region), and N Belize.

I. g. gularis (Wagler, 1829) – Pacific lowlands of S Mexico (Isthmus of Tehuantepec S to Tapanatepec, in Oaxaca), also interior Guatemala, El Salvador, Honduras and W Nicaragua.

I. g. flavescens A. R. Phillips, 1966 – Guerrero, in S Mexico.

Descriptive notes. 23–25·5 cm; male average 85·7 g, female average 69·4 g. A robust oriole with thick straight bill. Nominate race has head and underparts bright orange, with black lores and chin to uppermost breast (bib); mantle and back black, rump and uppertail-coverts orange to orange-yellow; upperwing black, orange to yellow shoulder patch (lesser and median coverts), greater coverts broadly tipped white (prominent wingbar), primaries broadly edged white at base (small patch on closed wing), and secondaries and tertials edged white; tail black; iris brown; bill black, basal half of lower mandible bluish-grey; legs bluish-grey. Sexes similar. Juvenile has orange areas of plumage yellowish, lacks black bib, has mantle and back olive, wing and tail dusky, greater coverts tipped paler, no shoulder patch; immature similar to adult but duller, back orange-tinged olive, pale colours in wing greatly reduced. Race *mentalis* is like nominate, but smaller; *flavescens* is intermediate in size between nominate and previous, and differs in having orange areas of plumage replaced by yellow. Voice. Song a varied series of loud whistles, sometimes combining slow and fast sections. Calls include nasal "nyenk", often repeated, also "chiu" and plaintive "chu wee chu".

Habitat. Woodland and scrub, riparian woodland, savannas; seems to have a liking for *Mimosa* trees. Lowlands to 1500 m.

Food and Feeding. Arthropods, presumably also small vertebrates; also fruits and nectar. Ants (Formicidae) found among stomach contents. Feeds on fruits of the native trees *Celtis* (Ulmaceae), *Ehretia tinifolia* (Boraginaceae) and *Talisia olivaeformis* (Sapindaceae); reported also as feeding on cultivated fruits. Nestling diet in S USA (Texas) mostly insects, with a good proportion of cryptic stick-insects (Phasmida). Forages in pairs and in small groups; often mixes with other orioles.

Breeding. Season late Apr–Aug in USA and NE Mexico, May–Jul in S Mexico (Oaxaca) and Mar–Jun in El Salvador; apparently double-brooded. Monogamous. Solitary breeder, territories well spaced. Nest built by female, work taking up to 26 days, an elongate pensile bag 35–65 cm long (the biggest nest built by any oriole), resembling nest of *Cacicus*, made from grass and other plant fibres, usually placed rather high up and exposed in tree, often a thorny one, including acacia (*Acacia*) species harbouring aggressive stinging ants, or sometimes hanging from power line; in El Salvador may nest in same tree as other orioles (*I. pustulatus* and *I. pectoralis*); in USA (Texas) sometimes with Great Kiskadees (*Pitangus sulphuratus*) and Couch's Kingbirds (*Tyrannus couchii*), both aggressive to avian predators. Clutch 3–4 eggs, rarely 5, bluish-white with blackish lines, scrawls and spots, mean dimensions 27·4 × 18·8 mm; incubation by female, period 14 days; chicks fed by both sexes, no information on duration of nestling period. Nests parasitized by *Molothrus aeneus*, e.g. one of six nests in Oaxaca (S Mexico) was parasitized.

Movements. Resident.

Status and Conservation. Not globally threatened. Common to fairly common throughout range. A rather abundant oriole in some places, with increasing populations. First recorded in S USA in 1930s, and first confirmed breeding in 1951; since then has increased in numbers to become commonest member of genus in Rio Grande Valley.

Bibliography. Binford (1989), Brush (1998b), Dickerman (2007), Dickey & van Rossem (1938), Flood (1989), Grimes (1953), Hathcock & Brush (2004), Howell & Webb (1995), Janzen (1971), Jaramillo & Burke (1999), Kantak (1979), Lowther (1995), McCarthy (2006), Pleasants (1981, 1993), Rowley (1984), Steinbacher (1981), Sutton & Pettingill (1943).

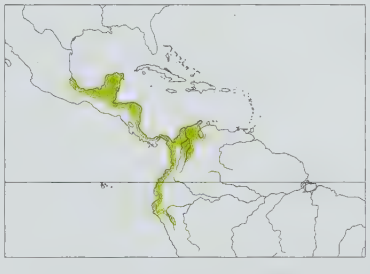
36. Yellow-tailed Oriole

Icterus mesomelas

French: Oriole à queue jaune **German**: Gelbschwanztrupial **Spanish**: Turpial Coliamarillo

Taxonomy. *Ps.*[*arocolius*] *mesomelas* Wagler, 1829, Chalcaltianges, Veracruz, Mexico.

Hybridizes rarely with *I. chrysater*. Form *I. xantholemus*, known only by type specimen supposedly from Ecuador, was previously thought to be immature of present species or perhaps a hybrid of unknown parentage, but has now been shown to be a synonym of *Xanthopsar flavus*. Four subspecies recognized.



Subspecies and Distribution.

I. m. mesomelas (Wagler, 1929) – S Mexico (from Veracruz) S to Honduras.

I. m. salvinii Cassin, 1867 – Caribbean lowlands from Nicaragua S to W Panama (Bocas del Toro).

I. m carrikeri Todd, 1917 – Panama (from E of Canal) S on both coasts to W & C Colombia and NW Venezuela (Zulia).

I. m. taczanowskii Ridgway, 1901 – Pacific coast of Ecuador and NW Peru (Tumbes, also upper Marañón Valley).

Descriptive notes. 20·5–23·5 cm; male average 49·7 g, female average 38·5 g. Nominate race has face, throat to centre of breast, mantle and back, most of wing and central tail feathers black; remainder of head and underparts, rump, uppertail-coverts and outer tail feathers bright yellow, more golden on head; lesser, median and most of inner greater upperwing-coverts bright yellow (striking epaulet), inner secondaries and tertials edged yellowish, primaries edged white distally; iris dark brown; bill black, base of lower mandible grey; legs bluish-grey. Sexes similar. Juvenile is greenish-yellow above and drab yellow bellow; immature has black face and throat like adult, but dusky olivaceous upperparts, wing and tail. Races differ mainly in plumage coloration, bill shape and size: *salvinii* lacks yellowish edgings on secondaries, is more orange-tinged on head; *carrikeri* resembles previous, but on average paler orange, and has smaller bill; *taczanowskii* is smaller in size, and has tertial edges white, more extensive yellow in tail. Voice. Rich mellow song, by both sexes, consists of repeated phrases in which warbles mixed with trills; songs in Ecuador harsher in tone. Call a nasal "chew", also harder "chuk" or "chik".

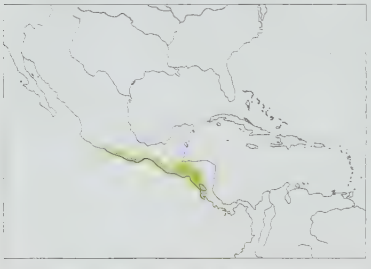
Habitat. Inhabits humid places, including thick low shrubbery and bamboo, second-growth forest, swamp-forest, also banana plantations; commonly near water. Lowlands to c. 500 m; locally to 1000 m (*salvinii*), and up to 1750 m (*taczanowskii*).

Food and Feeding. Insects and other arthropods, e.g. centipedes (Chilopoda); also some fruit and nectar (including *Erythrina*). Stomach contents included ants (Formicidae), cockroaches (Blattodea), crickets (Orthoptera), several families of beetles (Coleoptera), and caterpillars. Feeds on fruits on the native trees *Ehretia tinifolia* (Boraginaceae) and *Talisia olivaeformis* (Sapindaceae). Unlike congeners, tends to keep low down in dense vegetation. Arthropods usually gleaned from foliage. Forages in pairs and in family groups; sometimes with other orioles.

Breeding. Season Apr–Jun in Costa Rica and Panama, and Sept–Nov in N Colombia. Probably monogamous. Solitary breeder. Nest a pendent shallow basket woven from slender plant fibres, with strong but open fabric, external diameter 11–12 cm, external depth 9 cm, attached to parallel twigs or branch fork 2–4 m up in tree; one nest in Colombia was attached to underside of leaf of an ornamental palm species growing in garden. Clutch 3 eggs, light blue with spots of brown and black, mean dimensions 23·9 × 17·8 mm; incubation by female, period 14 days; chicks fed by both parents, nestling period 12–13 days.

Movements. Appears resident.

Status and Conservation. Not globally threatened. Fairly common to common in much of range; uncommon in Peru. Widely captured as a cagebird, and for that reason locally scarce in Costa Rica. Found in many protected areas, such as Barro Colorado Nature Monument and Soberanía National Park (Panama).



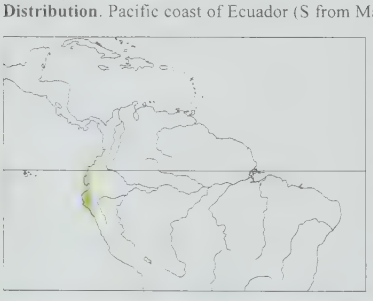
Bibliography. Barreiro & Pérez del Val (2000), Darlington (1931), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995), Jaramillo & Burke (1999), Kantak (1979), McCarthy (2006), Olson (1981c, 1983a), Ridgely & Greenfield (2001a, 2001b), Schulenberg & Parker (1981), Skutch (1954), Stiles & Skutch (1989), Wetmore *et al.* (1984).

37. Spot-breasted Oriole

Icterus pectoralis

French: Oriole maculé **German**: Tropfentrupial **Spanish**: Turpial Pechipinto
Other common names: Spotted Oriole

Taxonomy. *Ps.*[*arocolius*] *pectoralis* Wagler, 1829, Totolapán, Oaxaca, Mexico.
Closely related to *I. graceannae*. Four subspecies recognized.
Subspecies and Distribution.
I. p. carolynae Dickerman, 1981 – S Mexico (Pacific slope of Guerrero and adjacent Oaxaca).
I. p. pectoralis (Wagler, 1829) – SE Mexico (E Oaxaca and C Chiapas S to Tonalá).
I. p. guttulatus Lafresnaye, 1844 – SE Mexico (from Pijiapán, in Chiapas) S to arid valleys of Guatemala, Honduras and NW Nicaragua.
I. p. espinachi Ridgway, 1882 – SW Nicaragua (Rivas) and NW Costa Rica (Guanacaste).
Introduced (race *espinachi*) in SE USA (Miami, in Florida) and on Cocos I, in Costa Rica.



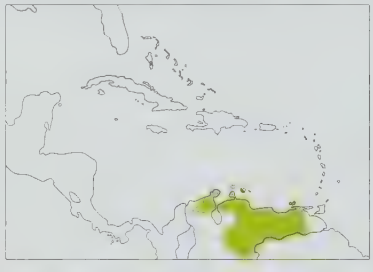
Descriptive notes. c. 21 cm; male 52·6 g, female 44·9 g. Male nominate race is mostly pale orange, somewhat deeper orange on head, with black face, throat to upper breast, mantle and back, wing and tail; lesser and median upperwing-coverts orange-yellow, primaries edged white at base (forming small pale patch), inner secondaries and tertials broadly edged white (prominent white patch on closed wing); pale orange below, breast and breast side with black spots; iris dark brown; bill black, base of lower mandible grey; legs greyish-blue. Female is similar to male, but slightly duller. Juvenile has orange parts of plumage duller and yellower, with olive-brown back, lacks black on face and breast, median and greater coverts tipped yellowish; immature more like adult, but duller, back feathers black with olive fringes, black spots on breast often absent. Races differ mainly in plumage: *carolynae* is similar to nominate, but breast spots larger, usually forming black band on side of breast that meets black of throat; *espinachi* is like nominate, but more brightly coloured; *guttulatus* is the most brightly orange. Voice. Male song a slow series of rich clear whistles, variable, sometimes phrases repeated several times, sometimes series protracted; female song simpler. Calls include loud nasal "nyeh" notes, often repeated, also sharper notes.
Habitat. Arid thorny woodland and scrub, with acacia (*Acacia*), mesquite (*Prosopis*), etc.; also edges of shade coffee plantations, pastures with large trees, trees around ranches, and in villages. Lowlands; reported at up to 900 m (*guttulatus*).
Food and Feeding. Insects and other arthropods, fruits and nectar. Gleans insects from foliage, also finds hidden prey in rolled leaves. Commonly observed at flowers of *Erythrina* trees, also in *Caesalpinia* and *Gliricidia*. Forages in pairs and in family groups; also in small non-breeding flocks. Often associates with other orioles.
Breeding. Season Apr–Jul; second broods reported. Monogamous; territorial. Nest built by female, with some help from male, said to be more carefully woven than those of congeners, a pensile pouch of grass, vine tendrils, thin roots, other plant fibres and black fungal rhizomorphs, 25–60 cm in external height, 15 cm wide at base, bottom lined with fine fibres, placed rather high up (6–18 m) in bush or tree, often in thorny tree, including acacia species that harbour aggressive stinging ants (Formicidae), or sometimes suspended from power line; tree may contain active nests of other orioles, particularly *I. gularis* and *I. pustulatus*. Clutch 3 eggs, bluish-white with blackish and lilac spots and scrawls, mean dimensions 22·8 × 17·8 mm; incubation by female only, chicks fed by both sexes, no information on duration of incubation and nestling periods. Nests parasitized by *Molothrus aeneus*; reported as a host of *Molothrus oryzivorus* in Nicaragua, where seen to feed fledgling of that species.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common to uncommon throughout most of range; locally common in Mexico; uncommon and local in Costa Rica. Generally less abundant than other orioles in the same habitats, but tolerant of human-made modifications of habitat. Introduced successfully in S Florida (USA) and on Cocos I (off Costa Rica); first confirmed breeding in Florida in late 1940s, presumably following escape of cagebirds, and appears to be thriving in 21st century.
Bibliography. Brookfield & Griswald (1957), Dickerman (1981a, 2007), Dickey & van Rossem (1938), Gillespie (2000), Gómez (1983), Howell & Webb (1995), Janzen (1971), Jaramillo & Burke (1999), Lowther (1995), McCrary & Gates (2007), Owre (1973), Skutch (1954), Stiles & Skutch (1989).

38. White-edged Oriole

Icterus graceannae

French: Oriole leucoptère **German**: Weißschwingentrupial **Spanish**: Turpial Aliblanco

Taxonomy. *Icterus Grace-Annae* Cassin, 1867, Ecuador or Peru.
Monotypic.
Distribution. Pacific coast of Ecuador (S from Manabí) and Peru (S to La Libertad).



Descriptive notes. 19–20 cm; male average 45·9 g, female average 37·1 g. Plumage is mostly orange-yellow, with black lores (mask), throat to upper breast and back; wing mostly black, lesser and median coverts pale yellow (medians palest), innermost secondaries and tertials broadly edged white basally (prominent patch on closed wing); tail black, outermost feather edged white, sometimes up to three adjacent rectrices with white tips; iris dark brown; bill black, base of lower mandible grey; legs greyish-blue. Sexes similar. Juvenile is duller and greener-looking than adult, with back feathers tipped olive, lesser and median coverts dull blackish with yellow tips, white on tertials and inner secondaries less striking. Voice. Song described as a series of musical phrases, each one repeated several times. Calls include a nasal whistle.
Habitat. Desert scrub, xeric deciduous woodland with mesquite (*Prosopis*), also Tumbesian dry forest with *Ceiba trichistandra*; extends into nearby modified habitats. Mostly below 400 m, but to 1700 m in Loja (Ecuador) and to 1300 m in Piura (Peru).
Food and Feeding. Little information. Diet presumably arthropods, nectar and fruit. Found in pairs and in family groups.
Breeding. Season Feb–Mar in Ecuador, but somewhat variable, dependent on rains; one nest found in May in Peru. Apparently monogamous. Solitary. Two nests in Ecuador each a pendent bag, externally 8–10 cm wide and 9–11·5 cm deep, a third nest described as a shallow bag, made from pale brown plant fibres, so thin that structure almost transparent, attached by rim to twigs 1·8–4 m above ground in "arrayán" tree (*Myrcianthes*), *Prosopis juliflora* or *Scutia*. Clutch 2–3 eggs, cream-coloured with diffuse dark brown spots and blotches, mean dimensions 24·7 × 17·8 mm; chicks fed by both sexes. Parasitized by *Molothrus bonariensis*, one nest containing three of latter's eggs and two host chicks. No other information.
Movements. Apparently resident, even during dry season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Seems to be relatively numerous and tolerant of moderate disturbances. Estimated range of occurrence c. 78,000 km².
Bibliography. Jaramillo & Burke (1999), Knowlton (2010), Marchant (1958, 1960), Omland *et al.* (1999), Price *et al.* (2007), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Tinoco (2009).

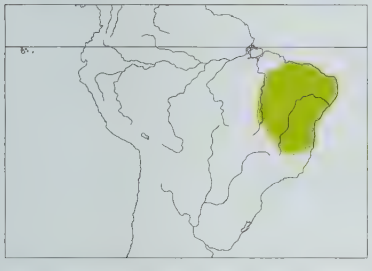
39. Venezuelan Troupial

Icterus icterus

French: Oriole troupiale **German**: Orangetrupial **Spanish**: Turpial Venezolano
Other common names: (Common) Troupial

Taxonomy. *O.*[*riolus*] *icterus* Linnaeus, 1766, "in America calidiore" = Cumaná, Sucre, Venezuela.
Closely related to *I. jamacaii* and *I. croconotus*, and all are often regarded as conspecific, but no intermediates known, and no hybrids reported in areas where sympatry with escaped cagebirds occurs (e.g. around Belém, in Pará, in N Brazil). Distribution of black and orange in plumage of race *metae* slightly approaches that of *I. croconotus*, but this probably convergence, as other characters of *metae* are unique. Three subspecies recognized.
Subspecies and Distribution.
I. i. ridgwayi (E. J. O. Hartert, 1902) – N Colombia (Guajira and N Cesar) and lowlands of N Venezuela E to Sucre and Margarita I; also Netherlands Antilles (Aruba and Curaçao).
I. i. icterus (Linnaeus, 1766) – N & C Venezuela from Carabobo and W Apure to S Monagas and N Bolívar.
I. i. metae Phelps, Jr & Aveledo, 1966 – W Venezuela (S Apure) and adjacent NE Colombia (Arauca, Vichada).
Introduced (*ridgwayi*) to Puerto Rico, Virgin Is and E Netherlands Antilles (Bonaire).

Descriptive notes. 23–27 cm; in Venezuela, male average 67·3 g, female average 58·5 g; for introduced population in Puerto Rico, male 65·5–88 g, female 60·9–73·1 g. Nominate race has head to upper nape and upper breast black (ragged lower border on breast), hindcollar, rump to uppertail-coverts and underparts below breast rich orange-yellow, lower mantle and back black; upperwing black, lesser coverts orange, median and inner greater coverts white, tertials and inner secondaries with broad white outer edges (elongated white patch extending from epaulet to rear tertials on closed wing); tail solidly black; iris yellow, conspicuous area of bright blue bare skin around eye; bill black, basal half of lower mandible grey; legs bluish-grey. Sexes similar. Juvenile is patterned much like adult, but duller, more yellowish and brownish-black, with bare ocular patch smaller and greyer. Race *ridgwayi* is larger than nominate, with longer bill and stronger legs; *metae* differs in having the whole nape and lower back orange, instead of black (variable, some individuals very like nominate), and has all greater upperwing-coverts black, dividing white wing patch into two. Voice. Song, by both sexes, loud repetitions of rich melodious phrases of 2–4 elements, e.g. "troo-pear-pééá", elements usually warbles or modulated whistles, rarely pure notes; song quite variable, order of elements may change, several elements may occur in a single population, and pauses between notes vary in length. Pair-members sometimes duet. Mimicry of other birds recorded. Calls include nasal notes and pleasant whistles. In flight produces audible wing noise.
Habitat. In Aruba and coastal Venezuela found in xerophytic woodland of acacia (*Acacia*) and arborescent cacti. Nominate race and *metae* mostly in pastures and savanna in dry or seasonal woodlands. On Curaçao (*ridgwayi*) mainly in old fruit plantations, particularly of mango (*Mangifera indica*) and sapodilla (*Manilkara zapota*). In Puerto Rico, where introduced, most common in drier SW corner. Lowlands.
Food and Feeding. Nectar, fruits, seeds, arthropods and small vertebrates. Stomach contents from Aruba and Curaçao included mostly insects, i.e. lepidopteran larvae, adult beetles (Coleoptera) and adult hymenopterans, also fruits. Nectar obtained from flowers of, among others, *Pithecellobium saman*, *Erythrina* species (e.g. *Erythrina poeppigiana*) and *Cereus* cacti; reported as eating floral parts of *Opuntia wentiana* on Aruba. Feeds on cultivated papayas (*Carica*), mangos, sapodillas and annonas (*Annona*), and wild fruits (cacti). Seeds taken include those of grasses of genus *Andropogon*. Forages in pairs and in family groups, sometimes with other orioles (e.g. *I. nigrogularis*). In *llanos* of Colombia and Venezuela, roosts individually in nests of other bird species, mostly those of Rufous-fronted Thornbird (*Phacellodomus rufifrons*).
Breeding. Season Mar–Dec, during both wet and dry seasons, in Colombia and Venezuela, and probably in all months on Aruba and Curaçao; usually attempts two or three broods per season. Presumably monogamous. Solitary breeder, strongly territorial. In N of range (Aruba, Curaçao and coastal Venezuela), race *ridgwayi* commonly builds shallow pensile pouch of plant fibres, lined with finer material, attached to arborescent cactus (*Stenocereus griseus*) or to small tree (acacia, *Crescentia cujete*), but may utilize old nest of *I. nigrogularis* or Tropical Mockingbird (*Mimus gilvus*), or domed stick nest of Pale-breasted Spinetail (*Synallaxis albescens*); in *llanos* of Venezuela, nominate race usually uses covered stick nest built by Rufous-fronted Thornbird or nest of other oriole or Great Kiskadee (*Pitangus sulphuratus*), sometimes interacting aggressively with other birds in order to pirate such nests, and destroying eggs and small chicks (even of competing troupial pairs); Rufous-fronted Thornbird nest is multi-chambered, and present species may eventually co-exist with other birds (even thornbirds) using same structure; nesting behaviour of race *metae* probably similar to that of nominate; when using furnariid nest, commonly removes sticks to enlarge original entrance, or opens new ones, to gain easier access to brood-chamber, invariably



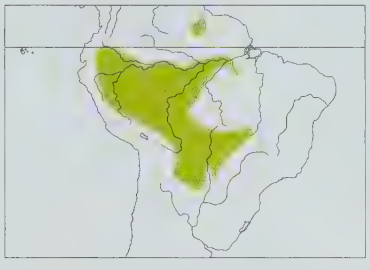
adding a lining of plant fibres. Clutch usually 3 eggs, sometimes 2, pinkish-white, spotted and marked in black, brown and grey, mean dimensions 27·8 × 20 mm (*ridgwayi*), 28 × 18·4 mm (nominate); incubation by female, no information on duration; chicks fed by both sexes, nestling period 21–23 days; both sexes defend nest. Nests parasitized by *Molothrus bonariensis*.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common to fairly common or locally common; said to be abundant on Aruba and Curaçao. Reports of this species from several of the Lesser Antilles believed to involve escaped cagebirds. Following introductions of race *ridgwayi* in Netherlands Antilles (Bonaire), Puerto Rico and Virgin Is (St Thomas), appears to have succeeded in establishing viable populations. Much prized as a cagebird and commonly captured for this purpose. Occurs in several protected areas in Venezuela (e.g. Guatopo and Aguaro-Guariquito National Parks) and Colombia.
Bibliography. Ascanio (1997), Cherrie (1916), Cruz & Andrews (1989), Earsom (2004), Hilty (2003), Hilty & Brown (1986), Lindell (1996), Lindell & Bosque (1999), Restall *et al.* (2006), Ridgely & Tudor (1989), Skutch (1969), Thomas (1979), Voous (1983), Wiley (1985).

40. Campo Troupial

Icterus jamacaii

French: Oriole des campos **German**: Campotrupial **Spanish**: Turpial Brasileño
Other common names: Campo Oriole

Taxonomy. *O.*[*riolus*] *Jamacaii* J. F. Gmelin, 1788, Ceará, Brazil.
Closely related to *I. icterus* and *I. croconotus*; the three are often regarded as conspecific, but no intermediates or hybrids known in limited areas where ranges of present species and *I. croconotus* overlap in Brazil (R Palmeiras, in Tocantins), and no hybrids reported in areas where sympatry with escaped captives occurs (e.g. around Belém, in Pará, in N Brazil). Proposed taxon *paraguayae* (described from 265 km W of Puerto Casao, in Paraguayan Chaco), sometimes treated as a race of present species or of *I. croconotus*, is subsumed in race *strictifrons* of latter. Monotypic.
Distribution. NE Brazil from Maranhão and Tocantins E to Rio Grande do Norte and Paraíba, S to N Minas Gerais.



Descriptive notes. c. 23–26 cm; male average 67·3 g, female average 58·5 g. Has head to upper breast black (ragged lower border on breast), mantle, rump to uppertail-coverts and underparts below breast rich orange-yellow, back black; upperwing black, lesser and median coverts yellowish-orange, inner remiges (including longer tertials) with broad white outer edges (prominent patch on closed wing); tail solidly black; iris yellow, small area of blue bare skin around eye; bill black, base of lower mandible grey; legs bluish-grey. Sexes similar. Juvenile is similar in pattern to adult, but duller, generally looking brownish-black and dull yellowish-orange. Voice. Song, by both sexes, consists of repetitions of whistled melodious phrases, e.g. "swéét-chip-swéét-tru-rú", with second and fourth notes much shorter; may also sing repeated series of pleasant warbles, "chwe koro che-che koro che-che...", partners sometimes combining in duet. Known to mimic other birds. Calls include various harsh notes, also "crik". Produces audible wing noise in flight.
Habitat. Clearings and edges in primary and secondary *caatinga* (dry forest); regularly visits orchards and gardens, even in small towns. Lowlands.
Food and Feeding. Insects and other arthropods, probably small vertebrates; also nectar and fruits. Insects in stomach contents included 126 larvae of flies (Diptera), also beetles (Coleoptera) and bugs (Hemiptera). Feeds on fruits of cacti, also on those of cultivated plants such as papayas (*Carica*), mangos (*Mangifera indica*) and annonas (*Annona*). Takes nectar from flowers of *Erythrina* and *Cereus*. Quite arboreal, often hanging upside-down while foraging. Forages singly, in pairs and in family parties.
Breeding. Season Dec–Mar (Minas Gerais); breeds during rainy season. Presumably monogamous. Solitary breeder, probably territorial. Does not build a nest, instead utilizes covered nest built by other species, mostly furnariids such as Rufous-fronted Thornbird (*Phacellodomus rufifrons*) or Caatinga Cachalote (*Pseudoseisura cristata*); uses old nest or usurps new one, adds some lining material. May aggressively interact with other species, such as *Agelaioides fringillarius*, to obtain such nests. Only one individual, presumably female, incubates eggs, both sexes defend nest. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Reasonably common. Apparently has expanded its range W into E Pará. Very popular as a cagebird throughout Brazil, and much trapped; nests near human settlements are raided and chicks collected. Effects of trapping on wild populations not known; research needed. Replacement of *caatinga* forest and woodland by pastures and irrigated crops may be having adverse impact on local populations. Reported from several protected areas (e.g. Serra das Almas Natural Reserve, Seridó Ecological Station, Canudos Biological Station), which will integrate the Caatinga Biosphere Reserve (in formation).
Bibliography. Fraga (2006), Jaramillo & Burke (1999), Novaes & Lima (1998), Pacheco & Olmos (2006), Pinto (1967), Santos *et al.* (2010), Schubart *et al.* (1965), da Silva & Oren (1990).

41. Orange-backed Troupial

Icterus croconotus

French: Oriole à dos orange **German**: Orangerückentrupial **Spanish**: Turpial Amazónico
Other common names: Orange-backed Oriole

Taxonomy. *Ps.*[*arocolius*] *croconotus* Wagler, 1829, "Mexico"; error = River Tapajós, Pará, Brazil.
Closely related to *I. icterus* and *I. jamacaii*; the three are often regarded as conspecific, but no intermediates or hybrids known in limited areas where ranges of present species and *I. jamacaii* overlap in Brazil (R Palmeiras, in Tocantins), and no hybrids reported in areas where sympatry with escaped captives occurs (e.g. around Belém, in Pará, in N Brazil). Proposed taxon *paraguayae* (described from 265 km W of Puerto Casao, in Paraguayan Chaco), sometimes treated as a race of *I. jamacaii*, is subsumed in race *strictifrons* of present species. Two subspecies recognized.
Subspecies and Distribution.
I. c. croconotus (Wagler, 1829) – S Guyana and adjacent N Brazil (Roraima and NW Amazonas); also SE Colombia (Putumayo), E Ecuador (Napo and Pastaza) and E Peru E in Brazil S of R Amazon to W Pará (R Tapajós, R Araguaia) and Tocantins, and S to NW Bolivia (Pando).
I. c. strictifrons Todd, 1924 – E Bolivia (Beni and Santa Cruz) E to C Brazil (Mato Grosso), and S through Paraguayan Chaco to N Argentina (Salta, Formosa and Chaco).

Descriptive notes. c. 23 cm; male average 48 g, female average 41 g. Nominate race has face, throat and upper breast black, crown to nape, neck side and upperparts, and underparts below breast rich orange-yellow, scapulars black; upperwing black, lesser and median coverts yellowish-orange, inner secondaries and some tertials with broad white outer edges (prominent patch on closed wing); tail solidly black; iris yellow, small area of bluish bare skin around eye; bill black, base of lower mandible grey; legs dark bluish-grey. Sexes similar. Juvenile is like adult in pattern, but much duller and lacks orange epaulet. Race *strictifrons* is like nominate, but with less black on forehead, more white in wing, also reputedly paler than nominate (but darkness of orange hue in plumage varies with nutritional status). Voice. Song, by both sexes, a repetition of whistled melodious phrases, e.g. "chee-chew-hwe-chew"; sequence of elements and pauses between elements variable. Partners often duet. Calls little known; in Peru, one contact call a loud and brief modulated whistle, "pee-o", with strong metallic overtones. Produces audible wing noise in flight.
Habitat. Nominate race mostly in riparian forest and edges of lakes, also in clearings and secondary growth; in Amazonia restricted mostly to *várzea* and rarely seen far from rivers. Race *strictifrons* inhabits similar habitat in Pantanal; S populations of this race frequent xeric, mostly deciduous *chaco* woodland and scrub, with thorny mesquite trees (*Prosopis*), arborescent cacti, and evergreen shrubs in genera *Capparis* and *Maytenus*. Lowlands; nominate race to 700 m.
Food and Feeding. Nectar, fruits, insects and other arthropods, and small vertebrates. Nectar taken from wild flowers, including, among others, *Erythrina*, *Cereus*, and many genera in Bombacaceae; also visits inflorescences of *Combretum lanceolatum*. Its role as potential pollinator is unstudied. Race *strictifrons* in the Chaco may rob tubular flowers of *Tabebuia*, *Cercidium* and *Capparis* by opening corolla tube or by crushing entire flowers. Quite arboreal, often hangs upside-down while foraging; in the Chaco seen to search clumps of epiphytic bromeliads (*Tillandsia duratii*). Usually forages in pairs or in family groups; associates with *I. pyrrhopterus*.
Breeding. Season Jul–Aug in S Colombia, and in S of range breeds during rainy season (Nov–Mar) in dry Chaco. Probably monogamous. Solitary breeder. Does not build a nest, instead utilizes covered nest built by other species, in Amazonia frequently *Psarocolius* or cacique (particularly *Cacicus cela*), in Paraguayan Chaco seen to inspect nests of *Procacicus solitarius*, and in Argentinian Chaco uses nest of thornbird (*Phacellodomus*); uses old abandoned nest or pirates new one, fighting with nest-builders and other birds, e.g. pair using a *Cacicus cela* nest near in Peru persistently harassed male oropendolas that displayed in same tree; in Argentina lines nest with dry yellow roots of a menispermaceous vine (possibly *Cissampelos*). Clutch probably 2–3 eggs; brood of three chicks reported from Argentina. No other information.
Movements. Mostly sedentary; local movements have been reported at edge of range in Argentinian Chaco.
Status and Conservation. Not globally threatened. Uncommon to locally common. Local but sometimes common in most of Amazonia; rather uncommon and local in Chaco, where possibly declining because of deforestation. Popular as a cagebird, and regularly trapped in Argentina, Bolivia, Brazil, Colombia and probably also rest of range; effects of trapping on wild populations have not been researched. This species' role as a pollinator of plants is potentially important, but hitherto unstudied. Found in several protected areas, e.g. Amacayacu National Park (Colombia), Pantanal Matto-grossense National Park (Brazil), Kaa-Iya del Gran Chaco and Amboró National Parks (Bolivia), and Defensores del Chaco and Agripino Enciso National Parks (Paraguay).

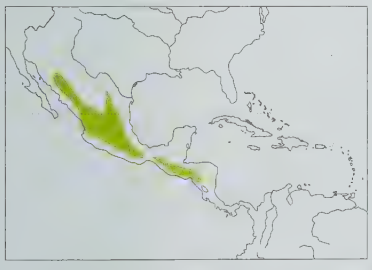
42. Bar-winged Oriole

Icterus maculialatus

French: Oriole unifascié **German**: Bindentrupial **Spanish**: Turpial Alibarrado

Taxonomy. *Icterus maculi-alatus* Cassin, 1848, Vera Cruz, Mexico; error = Cobán, Vera Paz, Guatemala.
Closest relatives uncertain. Monotypic.
Distribution. S Mexico (E Oaxaca and Chiapas) across C Guatemala to N El Salvador; possibly also Honduras.



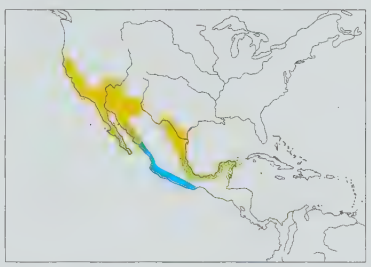
Descriptive notes. 20·5–23 cm; 31–59 g. Male has head to upper breast and back black, rump yellow, underparts below breast golden-yellow; upperwing black, yellow shoulder patch (lesser and median coverts), greater coverts broadly tipped white (conspicuous white wingbar), flight feathers edged white; tail solidly black; iris dark brown; bill black, base of lower mandible bluish-grey; legs bluish-grey. Female differs from male in having crown, entire upperparts (including rump), wings and tail olive, lacks yellow shoulder patch, has median coverts tipped yellowish, greater coverts tipped whitish. Juvenile is like female, but duller and browner, with no black on head, tips of greater coverts plain (no wingbar). Voice. Song a slow series of whistles and warbles. Common call a dry chatter.
Habitat. Xeric oak (*Quercus*) scrub and woodland, semi-deciduous woodland, open areas; mostly at 500–1800 m in mountain ranges and isolated volcanoes.
Food and Feeding. Little information. Diet probably insects and other arthropods, fruit and nectar. Visits flowering trees (possibly *Erythrina*) with other orioles. Usually found in pairs, family groups or small flocks.
Breeding. Birds in breeding condition during May–Jun. No other information.
Movements. Some local movements apparent, perhaps related to blooming seasons of trees.
Status and Conservation. Not globally threatened. Restricted-range species: present in North Central American Highlands EBA. Locally rare to uncommon, and generally scarce. Total range covers c. 80,000 km², and no indication of any declines. Probably the least known member of the genus.
Bibliography. Griscom (1932), Hardy *et al.* (1998), Howell & Webb (1995), Jacobsen *et al.* (2010), Jaramillo & Burke (1999), Peterson, Escalona-Segura & Griffith (1998), Peterson, Navarro-Sigüenza *et al.* (2003), Thurber *et al.* (1987).

43. Black-vented Oriole

Icterus wagleri

French: Oriole cul-noir **German**: Waglertrupial **Spanish**: Turpial Culinegro
Other common names: Wagler's Oriole

Taxonomy. *Icterus wagleri* P. L. Sclater, 1857, Mexico.
Related to *I. prosthemelas*. Two subspecies recognized.
Subspecies and Distribution.
I. w. castaneopectus Brewster, 1888 – NW Mexico in interior Sonora and Sinaloa and adjacent W Chihuahua.
I. w. wagleri P. L. Sclater, 1857 – C & S Mexico (from Durango, Coahuila and Nuevo León) S across C Guatemala, N El Salvador and SW Honduras to W Nicaragua.



Descriptive notes. 20·5–23 cm; 36·7–46·3 g, male average 41·3 g, female average 39 g. Male nominate race has head, throat, upper breast, mantle and upper back black, uppertail-coverts, lowermost belly and undertail-coverts black; rest of body orange-yellow, faint chestnut tinge just below black breast; upperwing black, orange-yellow epaulet (lesser and median coverts); tail solidly black; iris brown; bill black, base of lower mandible bluish-grey; legs bluish-grey. Female is like male, but duller, on average more yellow, less orange. Juvenile is duller than adult, crown and upperparts olive-buff, superciliary line and face and faint supercilium yellowish, median and greater upperwing-coverts tipped buff, underparts dull yellow; immature resembles juvenile, but crown and upperparts olive-grey, variable amount of black in face (lores, throat) and upper breast, tail blackish-brown. Race *castaneopectus* is very like nominate, but chestnut coloration below breast more extensive. Voice. Song not too musical, a mix of fast warbles with twittering and nasal or rasping notes. Calls include nasal "nye".
Habitat. Inhabits dry woodland and scrub, open areas with scattered trees; mostly in uplands, 500–2500 m.
Food and Feeding. Insects and other arthropods, also fruits and nectar. Gleans arthropods from foliage. Takes nectar from flowering trees of *Pseudobombax ellipticum* and *Erythrina oliviae*, and from brush-like inflorescences of the vine *Combretum fruticosum*. Frequent visitor to flowers of maguey (*Agave salmiana*) in Mexico. Usually in pairs or family groups. Dominant over both *I. bullockii* and *I. pustulatus* at flowering trees.
Breeding. Season Jun–Jul in S Mexico (Oaxaca) and May–Jul in El Salvador. Probably monogamous. Breeds solitarily. Shallow hammock-shaped nest, made from plant fibres, suspended at low or medium elevation in tree, sometimes stitched to underside of palm or banana leaves; one nest was attached to cables within a log cabin. Clutch 3–4 eggs, creamy white with dark brown and yellowish blotches, mostly at large end, mean dimensions of eggs attributed to this species 25 × 17·8 mm; combined incubation and nestling periods 34 days. Nests sometimes parasitized by *Molothrus aeneus*.
Movements. Undertakes some altitudinal movement, also local movements dependent on flowering season of trees. In S USA, nominate race accidental in Texas and *castaneopectus* accidental in Arizona.
Status and Conservation. Not globally threatened. Rather abundant, common to fairly common in most of range.
Bibliography. Binford (1989), Dickey & van Rossem (1938), Eguiarte *et al.* (1987), Gómez-Aiza & Zuria (2010), Gryj *et al.* (1990), Howell & Webb (1995), Jaramillo & Burke (1999), Komar *et al.* (2000), Lowther (1995), Toledo & Hernández (1979), Wauer (1970).

44. Hooded Oriole

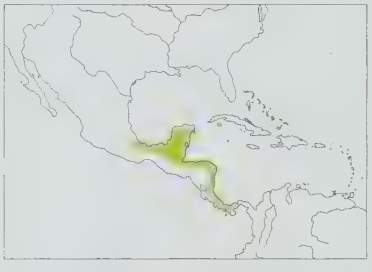
Icterus cucullatus

French: Oriole masqué **German**: Maskentrupial **Spanish**: Turpial Enmascarado

Taxonomy. *Icterus cucullatus* Swainson, 1827, Temascáltepec, Mexico.
Proposed race *restrictus*, described from W Mexico (Agiabampo, in extreme S Sonora), is synonymized with *nelsoni*; described races *duplexus* (from Mujeres I, off NE Yucatán, in Mexico), *cozumelae* (from Cozumel I, off NE Yucatán) and *masoni* (from Manatee, in Belize) are all subsumed in *igneus*. Five subspecies recognized.
Subspecies and Distribution.
I. c. nelsoni Ridgway, 1885 – breeds in SW USA (N California E to W Texas), S to NW Mexico (N Baja California, Sonora and N Chihuahua); non-breeding range extends S to Sinaloa (W Mexico).
I. c. trochiloides Grinnell, 1927 – C & S Baja California (from San Ignacio S to Cabo San Lucas).
I. c. cucullatus Swainson, 1827 – breeds from S USA (S Texas in middle Rio Grande Valley) S along edge of Mexican Plateau (Chihuahua and Nuevo León) to Puebla, Oaxaca and S Veracruz; winters from Jalisco S to Guerrero and S Oaxaca, in S Mexico.
I. c. sennetti Ridgway, 1901 – breeds from S USA (S Texas in lower Rio Grande Valley) S to E Mexico (S Tamaulipas); winters S to N Guerrero and Morelos, in S Mexico.
I. c. igneus Ridgway, 1885 – S Mexico from E Tabasco, N Chiapas and coastal Yucatán Peninsula (including adjacent islands of Holbox, Mujeres, Cozumel and others) S to N Belize.

Descriptive notes. 18·5–20 cm; male average 24·3 g, female average 23·1 g. A small orange-yellow oriole. Male nominate race is mostly deep orange, including most of head and neck and entire underparts below breast, but with loral area, face and chin to upper breast black, and mantle, scapulars and back black; upperwing black, white shoulder patch (median coverts) and narrower white wingbar (tips of greater coverts), remiges edged white; tail black with white tips; iris dark brown; bill black, bluish-grey base of lower mandible; legs blue-grey. Female has crown and nape greyish olive-yellow, upperparts olive, greyer on mantle, rump olive-green, face, throat and underparts yellowish, belly paler, flanks washed grey; upperwing blackish, median and greater coverts tipped white, remiges edged white, tail olive with paler sides; bare parts much as on male. Juvenile is similar to female, but much duller, olive-brown above and light olive-yellow below, belly whitish, wingbars buffish; immature male resembles female, but with blackish lores and bib. Races differ mainly in plumage tone and in bill length and shape: *nelsoni* male is paler orange-yellow than nominate, female has dull olive upperparts and yellowish-olive underparts; *trochiloides* is like previous in plumage colour, but both sexes have longer and thinner bill; *sennetti* male is yellow, rather than orange, female duller than nominate; *igneus* is even more richly coloured than nominate, male almost flame-orange, female strongly orange-yellow below. Voice. Song, covering wide frequency range, is a fast series of warbles, clicks and some chattering or rasping notes, also some mimicry of other species. Calls include whistled "wheet", hard "chit" and fast chatter.
Habitat. Palm groves (e.g. of *Washingtonia*), riparian habitats with scattered trees such as willows (*Salix*) and sycamores (*Platanus*), mesquite (*Prosopis*) woodland and scrub, deciduous woodland. Also parks and gardens, particularly those with native or exotic palms. Occurs from lowlands up to 1500 m.
Food and Feeding. Insects and other arthropods, nectar and fruits. Insects reported include lepidopteran caterpillars and beetles (Coleoptera). Takes nectar from flowers of wild and cultivated plants, including the tree *Erythrina breviflora*, the vine *Combretum fruticosum*, the weedy tree tobacco *Nicotiana glauca*, and herbaceous plants such as *Scrophularia californica*. Feeds on small berries, also cultivated loquats (*Eriobotrya japonica*). Punctures long tubular flowers to extract nectar; attracted to hummingbird (Trochilidae) feeders in gardens. Forages singly and in pairs sometimes in small groups; in non-breeding season may join other orioles, e.g. *I. graduacauda* and *I. gularis*.
Breeding. Season Apr–Jul in USA (California) and Feb–Sept in Mexico; depending on latitude, two or more broods reared per season, and recent evidence indicates that some N migrants breed again Jul–Aug in W Mexico (Sinaloa and S Baja California). Nest built by both sexes, cup-shaped, opening at side or top, made from slender wiry grasses, yucca (*Yucca*) and palm fibres, sparse lining of plant down or feathers, length 9–10 cm, average diameter 7·6 cm, placed at variable height in tree, e.g. California sycamore (*Platanus racemosus*), eucalypt (*Eucalyptus*) or oak (*Quercus*) among many others, or in wild or cultivated palm (54% of nests in some areas); nests in palms are pensile and stitched to underside of a leaf, in other sites can be semi-pensile and attached to twigs at top and sides; reported also as building in epiphytic *Tillandsia* and in clumps of mistletoe (Loranthaceae), and sometimes in building, with nest attached to thatched roof. Nest sometimes usurped by House Finch (*Carpodacus mexicanus*). Clutch 3–5 eggs, sometimes (race *trochiloides*) 2–4, white with buffish or bluish tinge, and with spots, blotches and irregular marks in blackish-brown, purple and grey, mean dimensions 21·6 × 15·2 mm; incubation by female, period 12–14 days; chicks fed by both sexes, no information on duration of nestling period; both

Cuban Oriole (*Icterus melanopsis*); 50. Hispaniolan Oriole (*Icterus dominicensis*); 51. Martinique Oriole (*Icterus bonana*); 52. St Lucia Oriole (*Icterus laudabilis*); 53. Montserrat Oriole (*Icterus oberi*); 54. Puerto Rican Oriole (*Icterus portoricensis*); 55. Orange-crowned Oriole (*Icterus auricapillus*); 56. Moriche Oriole (*Icterus chrysocephalus*); 57. Epaulet Oriole (*Icterus cayanensis*); 58. Variable Oriole (*Icterus pyrrhopterus*).



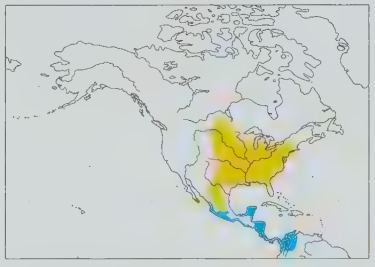
parents defend nest. Nests parasitized particularly by *Molothrus aeneus*, and reported as rearing its chicks; also by *Molothrus ater*.
Movements. N populations are short-distance migrants; those farther S in Mexico (particularly race *igneus*) seem mostly resident. N races *nelsoni* and nominate migrate S to W & S Mexico, and NE race *sennetti* moves S to S Mexico. Leaves Arizona breeding grounds Aug (adults) to Sept (immatures); arrives in California breeding grounds from late Mar. Vagrants recorded in coastal regions of NE USA and SW Canada.
Status and Conservation. Not globally threatened. Common to fairly common or locally common. Range expanding N in California. Tolerates moderate disturbance, and lives in parks and gardens, often in suburban areas.
Bibliography. Bendire (1895), Bent (1958), Cruden & Hermann-Parker (1977), Cruden & Toledo (1977), Ellison & Brush (2004), Gryj *et al.* (1990), Howell & Webb (1995), Jaramillo & Burke (1999), Lowther (1995), Miller & Stebbins (1964), Moore (1962), Pleasants & Albano (2001), Price *et al.* (2007), Rohwer, Hobson & Rohwer (2009), Sutton (1948).

45. Black-cowled Oriole

Icterus prosthemelas

French: Oriole monacal **German**: Gelbschultertrupial **Spanish**: Turpial Cabecinegro

Taxonomy. *Xanthornus prosthemelas* Strickland, 1850, Guatemala.
Closely related to *I. spurius*. Formerly regarded as conspecific with Greater Antillean group of species (*I. northropi*, *I. melanopsis*, *I. dominicensis* and *I. portoricensis*), but this treatment not supported by DNA data. Two subspecies recognized.
Subspecies and Distribution.
I. p. prosthemelas (Strickland, 1850) – SE Mexico (from Veracruz E to Yucatán and Quintana Roo) and Caribbean lowlands from Belize, N Guatemala and N Honduras S to C Costa Rica.
I. p. praecox A. R. Phillips & Dickerman, 1965 – SE Costa Rica (Limón) and W Panama (Bocas del Toro to Coclé).



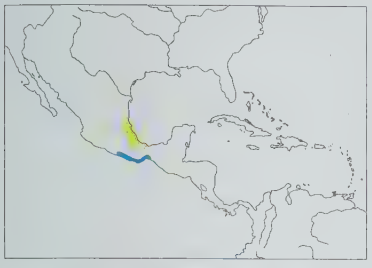
Descriptive notes. 18·5–21 cm; male average 32·5 g, female average 27·5 g. Male nominate race has head to breast and back black, rump and uppertail-coverts yellow; upperwing black, lesser and median coverts yellow (epaulet); tail solidly black; often variable chestnut tinge on lower breast separating black of breast from yellow of belly, flanks and undertail-coverts; iris brown; bill slender, black, bluish-grey base of lower mandible; legs dark grey. Female has forehead, lores, ear-coverts and throat to upper breast black, crown and upperparts olive, yellow wash on nape and rump and a few black spots on scapulars, upperwing and tail blackish, lesser and median coverts light yellow or blackish with yellow tips, underparts from lower breast yellow, bare parts as on male; variable, some females brighter and more like male, some (mainly in S of range) almost identical to male. Juvenile is like female, but duller, more olive, with less black on head (only lores and throat blackish), wing brownish, coverts tipped yellowish, tail plain olive; immature has blackish throat, wings and tail, olivaceous-yellow upperparts, and yellow underparts. Race *praecox* is virtually identical to nominate as adult, but juvenile has black of throat extending to lower breast. Voice. Song a rich warbling series of scratchy notes, rather quiet. Calls include a fast chatter, a variety of nasal notes e.g. "cheh", also soft "teeu".
Habitat. Occupies humid forest edges, riparian forest, old second-growth forest, banana plantations, and palm groves in open country. Nominate race mostly found in lowlands up to 700 m, rarely to 1000 m.
Food and Feeding. Insects and other arthropods, fruits and nectar. Feeds on fruits of *Cecropia*, *Ehretia tinifolia* and *Talisia olivaeformis*; takes nectar from flowers of *Erythrina* and *Inga* trees, also from the epiphyte *Columnea*. Finds animal prey by gleaning and probing in foliage, often hanging upside-down. Forages singly and in pairs, sometimes in small groups. Joins migratory orioles such as *I. spurius*; at roost also joins *I. galbula*.
Breeding. Season Mar–Jul in Costa Rica. Probably monogamous. Solitary breeder; in Yucatán Peninsula, single pairs may nest in or near colonies of *I. auratus*. Nest a short basket-shaped structure, external depth 8 cm, made from dark and light fibres, also rootlets, lined with brownish plant down, stitched to underside of palm leaf, or to leaves of banana plant or similar (e.g. once in a cultivated *Ravenala madagascariensis*); also, reported as nesting under eaves of houses, attaching nest to nails or wire. Clutch probably 3 eggs, based on brood size, mean dimensions of eggs attributed to this species 22·2 × 15·8 mm; both sexes feed chicks and both defend nest. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common to locally common in N of range; fairly abundant in Costa Rica; rarer in Panama. In Costa Rica, and possibly elsewhere, able to thrive in modified habitats. Found in several protected areas, such as Sian Ka'an Biosphere Reserve, in Mexico.
Bibliography. Alvarado *et al.* (2003), Howell & Webb (1995), Jaramillo & Burke (1999), Lack (1976), Lovette, Rickleffs & Bermingham (1999), Omland *et al.* (1999), Schönwetter & Meise (1981, 1982), Skutch (1954), Stiles & Skutch (1989), Wetmore *et al.* (1984).

46. Orchard Oriole

Icterus spurius

French: Oriole des vergers **German**: Gartentrupial **Spanish**: Turpial Castaño

Taxonomy. *O.[riolus] spurius* Linnaeus, 1766, South Carolina, USA.
Closely related to *I. prosthemelas*. Very closely related to, and often regarded as conspecific with, *I. fuertesi*; the two have discrete breeding ranges, but no evidence of intergradation where ranges approach one another, and songs apparently differ. Birds from C plateau of Mexico sometimes treated as a geographical race, *phillipsi*, on basis of larger size and slight differences in juvenile plumage, but such differences barely detectable. Treated as monotypic.
Distribution. Breeds in S Canada (S Saskatchewan, S Manitoba and extreme SE Ontario) and most of E USA (from Minnesota and Maine), S in Mexico to Jalisco, Michoacán and Hidalgo; winters from S Mexico (Colima and Veracruz) S throughout Central America to Colombia and extreme NW Venezuela.



Descriptive notes. 15–17 cm; male average 22·1 g, female average 20·8 g. A small, slender, short-tailed oriole. Male has head to chest and back black, rump and uppertail-coverts deep chestnut; upperwing black, lesser and median coverts chestnut (epaulet), greater coverts edged and tipped white (narrow white wingbar), flight-feathers edged white; tail all black; underparts below chest deep chestnut; in fresh plumage (non-breeding), feathers above tipped olive or pale chestnut, feathers of underparts tipped yellowish; iris dark brown; bill black, base of lower mandible bluish-grey; legs bluish-grey. Female is olive-green above and bright greenish-yellow below, breast tinged with ochraceous; upperwing brownish, median and greater coverts tipped white (two narrow wingbars), edges of flight-feathers white; bare parts as for male. Juvenile resembles female, but duller overall, crown washed yellowish, nape and back browner, wingbars buffish; immature male like female, but with black face and bib. Voice. Song, often in flight, variable, basically a high-pitched series of warbles, whistles and slurs. Two song types, short and long, sometimes recognized; long song (3–5 seconds) has more whistles and usually ends with downslurred note, short one (c. 2 seconds) is less musical. Female may sing; both adult and immature males regularly sing in wintering areas. Contact call a sharp "chuck"; chattering alarm call.
Habitat. Open woodland, avoiding dense forest. Breeds in rural areas with mesquite (*Prosopis juliflora*), pastures with scattered trees, riparian habitat, edges of marshes, orchards, suburban areas, gardens and parks. On wintering grounds found in second growth, savanna, roadside trees, parks and gardens. Mostly lowlands, in non-breeding quarters to c. 1600 m.
Food and Feeding. Stomach contents from breeding grounds contained 91% animal food and 9% plant food. Insects taken include flies (Diptera), ants (Formicidae), beetles (Coleoptera), Lepidoptera, and others; other arthropods mainly spiders (Araneae). Feeds on wild berries and cultivated fruits, less commonly on nectar. In winter often takes mistletoe berries (Loranthaceae). Nectar important in winter, and is taken from *Erythrina* tree species, such as *Erythrina fusca* and *Erythrina breviflora*, also from flowers of *Gliricidia*, and *Eugenia*, and the vine *Combretum fruticosum*. Probably an important pollinator of those species. Forages singly, in pairs and in small flocks. Moving flocks visit a succession of flowering trees. In non-breeding season flocks regularly contain up to several hundred individuals; winter roosts, sometimes with other orioles, of up to 400 individuals reported in Panama.
Breeding. Season Apr–Jun in S USA, later in N, and egg-laying not until Jun in Canada (Manitoba); single-brooded, but recent evidence indicates that some N migrants breed again (Jul–Aug) in W Mexico (Sinaloa and S Baja California). Apparently monogamous. Solitary breeder; reports also of semi-colonial nesting. Possibly sometimes co-operative breeder, with helpers; immature males occasionally help to feed chicks. Nest built by female, taking c. 6 days, a semi-pensile shallow basket woven mostly from green grass (which dries to yellow), lined with fine grass, plant down, cotton or feathers, mean external diameter 9·5 cm, external depth 8·4 cm, attached to fork of twigs, less often to strands of epiphytic Spanish moss (*Tillandsia usneoides*); variety of trees used, in Louisiana (S USA) mostly oak (*Quercus*), magnolia (*Magnolia*), elm (*Ulmus*), willow (*Salix*) and pecan (*Carya*), in Manitoba (Canada) mostly maple (*Acer*), green ash (*Fraxinus*), cottonwood (*Populus*) and willow; conifers used locally, and sometimes emergent plant within marsh. Clutch usually 4–6 eggs, occasionally 3 or 7, pale blue with dark purplish-brown blotches, spots, dots or irregular lines, mean dimensions 20·7 × 14·5 mm; incubation by female, sometimes fed by male, period 12–14 days; chicks fed by both sexes, nestling period 11–14 days (Manitoba). Nests parasitized by *Molothrus ater* and *Molothrus aeneus*.
Movements. Long-distance migrant. Almost all migrate to area from S Mexico (Colima and Veracruz) S to N Colombia and NW Venezuela; numbers of wintering individuals decline from Honduras S; overwinters rarely in Florida and Cuba. Leaves breeding grounds from Jul, almost all having departed from N parts of range by middle to end Aug; many move through W USA and W Mexico, some apparently stopping off in W Mexico to breed for a second time before continuing S. Ringed individuals moved from S USA (Alabama and Louisiana) to Belize and Honduras, and vice versa. Within wintering range probable local movements related to blooming times of trees. Occurs in Panama from Aug to mid-Mar. Leaves winter quarters in Mar–Apr, arriving late Mar in S USA and later, May, in N of range. Some individuals are believed to cross Gulf of Mexico during migration. Rare passage migrant in Cuba and vagrant in Bahamas and Jamaica.
Status and Conservation. Not globally threatened. Fairly common to uncommon; rather local, especially in N of range. Adapts well to artificial habitats. US census data suggest a slow decline in numbers between 1966 and 1996, but populations expanding in Canada.
Bibliography. Baker *et al.* (2003), Bendire (1895), Bent (1958), Cruden & Toledo (1977), Enstrom (1992a, 1992b, 1993), Graber & Graber (1954), Hofmann *et al.* (2007), Howell & Webb (1995), Leck (1974), Lowther (1995), McCarthy (2006), Morton (1979b), Rogers *et al.* (1982), Rohwer, Hobson & Rohwer (2009), Schaefer (1976), Scharf & Kren (1997), Sealy (1980), Stiles & Skutch (1989), Thomas (1946), Wetmore *et al.* (1984).

47. Fuertes's Oriole

Icterus fuertesi

French: Oriole de Fuertes **German**: Ockerbauchtrupial **Spanish**: Turpial de Fuertes
Other common names: Ochre Oriole

Taxonomy. *Icterus fuertesi* Chapman, 1911, Paso del Haba, 35 miles [c. 56 km] north-west of Tampico, Tamaulipas, Mexico.
Very closely related to, and often regarded as conspecific with, *I. spurius*; the two have discrete breeding ranges, but no evidence of intergradation where ranges approach one another, and songs apparently differ. Monotypic.
Distribution. Breeds in coastal E Mexico from S Tamaulipas S to S Veracruz; winter range imperfectly known, but reported S Guerrero, coastal Oaxaca and W Chiapas (S Mexico).
Descriptive notes. c. 16 cm; male 20·3 g, female 21 g. A small, slender, short-tailed oriole. Male has head to chest and back, upperwing and tail black, rump and uppertail-coverts, lesser and median upperwing-coverts, and underparts below chest rich ochre; greater upperwing-coverts edged and tipped white (narrow white wingbar), flight-feathers edged white; iris dark brown; bill black, base of lower mandible bluish-grey; legs bluish-grey. Differs from *I. spurius* in having chestnut colour replaced with ochre. Female is olive-green above, greenish-yellow below, breast more ochraceous, upperwing brownish, median and greater coverts tipped white (two narrow wingbars), edges of flight-feathers white, bare parts as for male; closely resembles female of *I. spurius*, and often indistinguishable, but some have paler rump and underparts. Juvenile resembles female, but

duller overall, head and upperparts grey-buff, paler on rump, narrow whitish wingbars, pale yellow below, breast tinged buff; immature male like female, but with black face and bib. Voice. Song 1·5–2·5 seconds long, a fast mix of chatters, clicks, buzzes and a few whistles, all notes with several harmonics; resembles song of *I. spurius*, but said to be softer and less brilliant, with notes shorter and less musical, and reaching higher frequencies (overall effect suggesting a rather accelerated tempo).

Habitat. Breeds in dense shrubs, consisting mostly of clumps of majagua (*Hibiscus tiliaceus*) and mangle negro (*Conocarpus erecta*), on coastal sand dunes; also farther inland, where found in hedgerows in cultivated land, and in thickets of bull's-horn acacia (*Acacia*).

Food and Feeding. Insects and other arthropods, nectar and fruits. Takes nectar from brush-like inflorescences of the vine *Combretum fruticosum*. Generally seen in pairs.

Breeding. Season Mar–Jul; appears to be single-brooded. Presumably monogamous. Nests solitarily, perhaps semi-colonial breeder at times. Nest a bag made from plant fibres (mostly grass), little or no lining used, external diameter 5–6·3 cm, external depth 10–11·5 cm, 2·5–6 m above ground and attached with strands of nest material to fork or twigs of shrub or tree, or sometimes stitched to leaves; reported nesting plants *Hibiscus tiliaceus*, small trees of *Psidium goiava*, and a strangler fig (*Ficus*). Clutch 2 eggs, white with purplish-black markings, one egg c. 20·3 × 14 mm; both sexes feed chicks. Nests parasitized by *Molothrus aeneus*. No other information.

Movements. Scant information. Believed to be a short-distance migrant, e.g. a few reported during boreal winter along Pacific slope of Mexico, from Guerrero E to Chiapas; more research needed. Accidental in extreme S USA (S Texas).

Status and Conservation. Not assessed. Poorly known; uncommon to common. Reported as common in 1954, and perhaps increasing in numbers. Has small global distribution, and habitat probably at some risk.

Bibliography. Baker *et al.* (2003), Chapman (1911), Dickerman (1964), Graber & Graber (1954), Gryj *et al.* (1990), Hardy *et al.* (1998), Hofmann *et al.* (2007), Howell & Webb (1995), Jaramillo & Burke (1999), Kiere *et al.* (2007), McCarthy (2006), Wetmore (1943).

48. **Bahama Oriole**

Icterus northropi

French: Oriole des Bahamas **German**: Bahamatrupial **Spanish**: Turpial de las Bahamas
Other common names: Northrop's Oriole; Greater Antillean Oriole (when treated as conspecific with *I. melanopsis*, *I. dominicensis* and *I. portoricensis*)

Taxonomy. *Icterus northropi* J. A. Allen, 1890, Andros Island, Bahamas. Often treated as conspecific with *I. melanopsis*, *I. dominicensis* and *I. portoricensis*, but recent morphological and behavioural studies suggest that all of these merit full species rank. Present species is closely related to *I. melanopsis*, and sequence divergence in mitochondrial DNA between them slight (0·7%), but differs in plumage and is more clearly sexually dichromatic. Monotypic.

Distribution. Andros and Abaco Is, in Bahamas.

Descriptive notes. c. 20–22 cm. Male is mostly black, including head to upper breast and back, wing and tail; rump, lesser and median upperwing-coverts (epaulet), underparts below upper breast, and entire underwing-coverts yellow; small white tips on outer rectrices; iris brown; bill black, base of lower mandible bluish-grey; legs grey-blue. Female is like male, but duller, with black areas of plumage more dusky. Juvenile is olive above, rump and uppertail-coverts yellower, throat yellow, becoming dull olive on breast, rest of underparts dull yellow, upperwing blackish-brown, median and greater coverts tipped yellow (two wingbars); immature is olive-grey above, head washed yellowish, lower back to uppertail-coverts greenish-yellow (brightest on rump), greenish-yellow below (brightest on belly), with lesser upperwing-coverts greenish-yellow, median coverts pale yellow, greater coverts narrowly fringed whitish, young male with variable amount of black on throat. Voice. Song lasts c. 2·4 seconds, comprises 6–11 emphatic whistles.

Habitat. Pine (*Pinus*) and broadleaf woodlands, gardens; often found near palms. Favours mature coppice woodland, with thatch palms (*Thrinax*) and introduced coconut palms (*Cocos nucifera*).

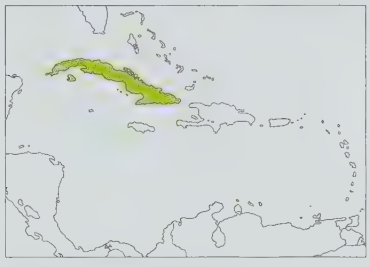
Food and Feeding. No information. Probably feeds on arthropods, fruit and nectar.

Breeding. Season mainly Feb–Jul. Pensile nest bag of plant fibres, mostly palm fibres, often attached (stitched) to underside of palm frond, or to leaves in tree, typically high up. Clutch 3 eggs, pale greenish-white with brown to dark brown spots. Three of eight nests observed were parasitized by *Molothrus bonariensis*. No other information.

Movements. Resident.

Status and Conservation. CRITICALLY ENDANGERED. Rare and declining. Not seen on Abaco since early 1990s, and appears to be extinct on that island; reasons for decline and apparent extirpation not known. Formerly common on Andros, but now scarce to rare, with estimated total population in 2009 only 127–254 individuals, and declining; reproductive output in some years extremely low. One major problem is the plant pathogen "lethal yellowing" (a phytoplasma), which attacks and quickly kills a wide variety of palm species; thought to be spread by the planthopper *Haplaxius crudus*, the disease has already eradicated coconut palm in parts of N Andros; lethal yellowing not yet found elsewhere on Andros, where palm populations remain healthy and oriole densities higher. A further threat is brood parasitism by *Molothrus bonariensis*, recently arrived on Andros and capable of causing serious problems for this icterid.

Bibliography. Anon. (2011a), Baltz (1996), Garrido *et al.* (2005), Lee *et al.* (1999), Omland *et al.* (1999), Price & Hayes (2009), Raffaele *et al.* (1998), Sturge *et al.* (2009).



49. **Cuban Oriole**

Icterus melanopsis

French: Oriole de Cuba **German**: Kubatrupial **Spanish**: Turpial Cubano
Other common names: Greater Antillean Oriole (when treated as conspecific with *I. northropi*, *I. dominicensis* and *I. portoricensis*)

Taxonomy. *Ps.*[*arocolius*] *melanopsis* Wagler, 1829, near Havana, Cuba.
Often treated as conspecific with *I. northropi*, *I. dominicensis* and *I. portoricensis*, but recent morphological and behavioural studies suggest that all of these merit full species rank. Present species is closely related to *I. northropi*, and sequence divergence in mitochondrial DNA between them slight (0·7%), but differs in plumage and is less clearly sexually dichromatic. Monotypic.

Distribution. Cuba, including I of Pines and cays off N coast (Guillermo, Coco and Paredón Grande).

Descriptive notes. c. 20 cm; male 35–42 g, female 30–38·5 g. Male is almost entirely black, with yellow rump, yellow lesser and median upperwing-coverts (epaulet), yellow bend of wing; yellow in underparts confined to thigh and small spots on undertail-coverts; iris brown; bill black, posterior half of lower mandible bluish-grey; legs dark blue-grey. Female is similar to male, but slightly duller. Juvenile is olive above, olive-green below, becoming yellower on vent, wing blackish, most feathers with greenish-olive edges; immature similar, but with black lores, chin and throat. Voice. Song lasts c. 3 seconds, comprises up to 11–12 mostly descending whistles, with narrow pitch range; some song phrases may suggest species' Cuban vernacular name, "solibio". Common calls a sharp "kit" and a nasal "whep".

Habitat. Forest edge, woodland, parks and gardens, often near palms.

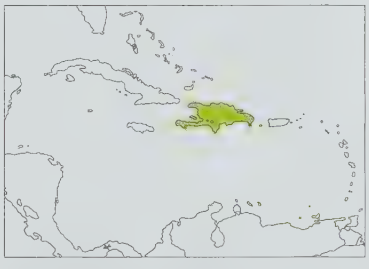
Food and Feeding. Takes insects and other arthropods, small vertebrates, fruits and nectar. Chicks fed mostly with insects and spiders (Araneae), also fruit pulp. Forages mostly in pairs or family groups.

Breeding. Season Feb–Jul, fledged chicks reported mostly in Jun; possibly two or three broods in a season, e.g. three nests (the first successful, the last abandoned) found between May and Jun at different fronds of one palm, presumably built by same pair. Presumably monogamous. Solitary breeder. Nest a pensile bag of plant fibres, mostly palm fibres, often stitched to underside of palm frond, less frequently suspended from leaves of other trees, five nests attached to fronds of Cuban royal palm (*Roystonea regia*) were 16–18 m above ground; other plants used include cultivated mango (*Mangifera indica*) and banana. Clutch 3–4 eggs, greenish-white with spots in brownish, olive and lilac-grey, mean dimensions 23·8 × 16·8 mm. No information on incubation and nestling periods. Nests parasitized by *Molothrus bonariensis*; in 1989, five pairs at National Botanical Garden (Havana) feeding total of nine cowbird chicks and one oriole chick. Immatures of unknown sex reported as breeding.

Movements. Resident.

Status and Conservation. Not globally threatened. Common to locally very common. Common even in modified environments. More recent data on cowbird parasitism needed.

Bibliography. Acosta & Mugica (1990), Balát & González (1982), Garrido & Kirkconnell (2000), Garrido *et al.* (2005), Gundlach (1876), Hardy *et al.* (1998), Jaramillo & Burke (1999), Omland *et al.* (1999), Price & Hayes (2009), Raffaele *et al.* (1998), Sturge *et al.* (2009).



50. **Hispaniolan Oriole**

Icterus dominicensis

French: Oriole à capuchon **German**: Hispaniolatrupial **Spanish**: Turpial de la Española
Other common names: Greater Antillean Oriole (when treated as conspecific with *I. northropi*, *I. melanopsis* and *I. portoricensis*)

Taxonomy. *O.*[*riolus*] *dominicensis* Linnaeus, 1766, Santo Domingo, Hispaniola.
Often treated as conspecific with *I. northropi*, *I. melanopsis* and *I. portoricensis*, but molecular-genetic data indicate that they are better treated as separate species; sometimes *I. prosthemelas* included within this group. Monotypic.

Distribution. Hispaniola (Haiti and Dominican Republic) and outlying islands (Tortue, Gonâve, I à Vache and Saona).

Descriptive notes. 20–22 cm; male 35–38·3 g, female 33–40 g. Male has head to back and down to belly and upper flanks black, rump and uppertail-coverts yellow; upperwing and tail black, lesser and median uppercoverts yellow (epaulet), yellow patch at bend of wing; underparts rearwards from lower belly, thigh and rear flanks yellow; iris brown; bill black; legs dark blue-grey. Female is similar to male, but duller. Immature has dark olive-green head to breast and upperparts, including tail, chestnut tinge in forehead and breast, wing blackish, most feathers with greenish-olive edges, median upperwing-coverts broadly tipped yellow, underparts below breast greenish-yellow. Voice. Song a series of high-pitched whistles. Common calls a sharp "kt" and a harsh "chrr".

Habitat. Broadleaf forest with palms, shade coffee plantations with palms; rarer in xeric woodland and scrub, gardens. Reported at up to 1100 m.

Food and Feeding. Arthropods, nectar and fruit. Nectar taken from flowers of *Erythrina*, also those of cultivated plants such as oranges and agaves (*Agave*). Fruit eaten includes bananas and annonas (*Annona*). Chicks fed mostly with insects and spiders (Araneae), also some fruit pulp. Usually forages in family groups; at times found in flocks of up to 50 individuals.

Breeding. Season Mar–Jun. Nest a pensile bag of plant fibres (mostly palm fibres), lined with cotton-like material, attached to underside of palm frond or banana leaf, or to leaves in tree. Clutch 3–4 eggs, white or bluish-white, finely spotted in russet and other shades of brown, 21·7 × 16·1 mm. Parasitized by *Molothrus bonariensis*. No further information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common and widespread throughout range. Population may suffer some decline owing to brood parasitism by recently arrived *Molothrus bonariensis*.

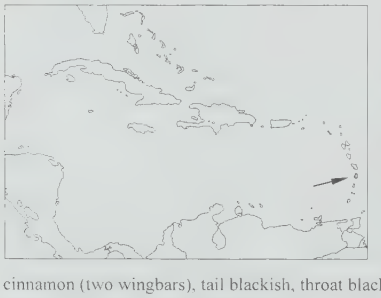
Bibliography. Brooks & Davalos (2001), Garrido *et al.* (2005), Keith *et al.* (2003), Lovette, Rickleffs & Bermingham (1999), Price & Hayes (2009), Raffaele *et al.* (1998), Sturge *et al.* (2009), Wetmore & Swales (1931).

51. Martinique Oriole

Icterus bonana

French: Oriole de Martinique **German**: Braunkopftrupial **Spanish**: Turpial de Martinica

Taxonomy. *O.*[*riolus*] *Bonana* Linnaeus, 1766, Martinique.
Relationships uncertain; analysis of mitochondrial DNA indicates that it is not closest relative of *I. laudabilis*, although the two are separated geographically by only 27 km. Monotypic.
Distribution. Martinique, in C Lesser Antilles.



Descriptive notes. 18–21 cm; one bird 29 g. Male has head to nape and most of breast dark chestnut to orange-chestnut, mantle, upper back, upperwing and tail blackish; lower back and rump orange-tawny, uppertail-coverts chestnut; lesser and median upperwing-coverts orange-tawny (distinctive epaulet); underparts below breast orange-tawny, thigh yellower, rearmost undertail-coverts blackish; iris dark brown; bill black, base of lower mandible pale bluish-grey; legs grey. Female is very like male, but slightly duller. Juvenile and immature undescribed. Voice. Song, infrequently recorded, consists of soft warbles. Call a harsh, scolding "cheeu".
Habitat. Mangroves, dry forest on limestone soils, also humid forest, plantations and towns; seems to prefer dry forest and mangroves. Sea-level to 700 m.
Food and Feeding. Insects and other arthropods; fruits, nectar. Animal items include caterpillars, ants (Formicidae) and stick-insects (Phasmida); feeds on wild and cultivated fruits, e.g. Malabar almond (*Terminalia catappa*). Gleans arthropods from green foliage, dry leaves, spider webs and vine tangles; also finds prey by removing loose pieces of bark, and probes into hollow twigs. Usually found in pairs or in family groups.
Breeding. Season Dec–Jul, mostly from Feb. Presumably monogamous. Nest a shallow pendent basket woven from strong fibres, often palm fibres, usually 2–4 m above ground and attached or stitched to underside of large leaf of tree, e.g. *Coccoloba grandifolia* or *Cecropia*, or to palm frond, or to leaf of banana or *Heliconia*. Clutch 2–3 eggs, white to pale bluish with brown spots and blotches; incubation period a minimum of 14 days; chicks fed by both sexes, nestling period 15 days; both sexes defend the nest. About 75% of nests parasitized by *Molothrus bonariensis*.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Lesser Antilles EBA. Common. Estimated total population at least 10,000 individuals; density 2·4 birds/ha in C Martinique. Recent decline in numbers, but apparently only slight. Considered to be at risk mainly because of its very small global range. Since 1970s has become less common, evidently owing to invasion of island by *Molothrus bonariensis*, which was able to spread as a result of deforestation and now parasitizes 75% of present species' nests each year; recent decrease in cowbird numbers, however, has enabled a slight recovery. Continued monitoring essential.
Bibliography. Anon. (2010d), Ascanio (2010), Babbs *et al.* (1987), Butchart & Stattersfield (2004), Collar *et al.* (1992), Evans (1990), Garrido *et al.* (2005), Lovette, Rickleffs & Bermingham (1999), Omland *et al.* (1999), Raffaele *et al.* (1998), Stattersfield & Capper (2000), Sturge *et al.* (2009).

52. St Lucia Oriole

Icterus laudabilis

French: Oriole de Sainte-Lucie **German**: Santa-Lucia-Trupial **Spanish**: Turpial de Santa Lucía

Taxonomy. *Icterus laudabilis* P. L. Sclater, 1871, St Lucia.
Formerly considered conspecific with *I. oberi*. Relationships uncertain; analysis of mitochondrial DNA indicates that it is not closest relative of *I. bonana*, although the two are separated geographically by only 27 km. Monotypic.
Distribution. St Lucia, in C Lesser Antilles.

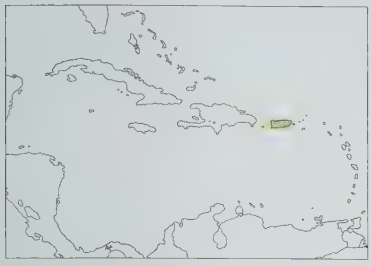
Descriptive notes. 20–22 cm; male average 39·8 g, female average 34·9 g. Male has head to upper back, breast, upperwing and tail black, feathers on neck with yellow bases; lower back, rump and uppertail-coverts orange-yellow, tinged with tawny, lesser and median upperwing-coverts orange to tawny (epaulet); underparts below breast orange-yellow; iris dark brown; bill black, bluish-grey patch on lower mandible, legs bluish-grey. Female is similar to male, but rump and underparts yellow, rather than orange. Juvenile has face black, rest of head cinnamon, upperparts brown, upperwing blackish, median and greater coverts tipped cinnamon (two wingbars), tail blackish, throat black, underparts cinnamon, becoming more tawny posteriorly; immature male resembles female, but black and orange-yellow areas much duller, tinged brownish or olive, wing feathers with olive edges. Voice. Song pleasant, composed of up to 7 notes, mostly loud ascending whistles. Call a harsh "chwee".
Habitat. Found in all types of forest and woodland, including dry scrub, coastal scrub and mangroves; more abundant in humid highland forest. Also frequents plantation edges. Sea-level to 700 m.
Food and Feeding. Insects and other arthropods, fruits and nectar. Fruits taken include cultivated bananas and mangoes (*Mangifera indica*). Chicks fed mostly with insects and spiders (Araneae), also fruit pulp. Probes and removes pieces of bark to expose hidden prey. Forages in pairs and in groups of up to ten individuals.
Breeding. Season Apr–Jul. Probably monogamous. Solitary breeder. Nest a pendent basket of plant fibres, stitched to underside of palm, *Heliconia* or banana leaves; sometimes in coconut palm (*Cocos nucifera*). Clutch 2–3 eggs, white with dark brown spots. Parasitized by *Molothrus bonariensis*. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Lesser Antilles EBA. Scarce. Has extremely small global range and very small population, thought to number 1000–2500 mature individuals and probably much closer to lower end of that range. Fairly widespread on the island in suitable habitat. Since 1930s has decreased and become more local, probably a consequence mainly of habitat loss combined with pesticide-spraying and brood parasitism by *Molothrus bonariensis*; rates of parasitism by latter sometimes very high, up to 75% of broods locally, but effects of this on present species' current populations not known. There is no evidence that this oriole is under any immediate significant threat, and its population appears stable at present; however, due to tiny range, any declines detected could rapidly lead to redlisting of the species.
Bibliography. Anon. (2010d), Babbs *et al.* (1988), Butchart & Stattersfield (2004), Danforth (1935), Diamond (1973), Evans (1990), Garrido *et al.* (2005), Hardy *et al.* (1998), Keith (1997), Lovette, Rickleffs & Bermingham (1999), Omland *et al.* (1999), Raffaele *et al.* (1998), Stattersfield & Capper (2000), Sturge *et al.* (2009), Toussaint (2007), Toussaint *et al.* (2009).

53. Montserrat Oriole

Icterus oberi

French: Oriole de Montserrat **German**: Montserrattrupial **Spanish**: Turpial de Montserrat

Taxonomy. *Icterus oberi* Lawrence, 1880, Montserrat.
Formerly considered conspecific with *I. laudabilis*. Monotypic.
Distribution. Montserrat, in NC Lesser Antilles.



Descriptive notes. 21 cm; male 36–39 g, female 31·5–35·8 g. The only Caribbean oriole with marked sexual dichromatism. Male has head to back, breast, upperwing and tail black, neck feathers with yellow bases, lower back, rump and uppertail-coverts yellow, tinged tawny; underparts below breast tawny-yellow; iris dark brown; bill black, bluish-grey patch on lower mandible; legs bluish-grey. Female has crown, upperparts and tail olive, washed yellow on crown, uppertail-coverts and tail, lores dark olive; upperwing brownish-olive, median and greater coverts with slightly paler tips (two wingbars); throat and underparts olive-yellow; bare parts as for male. Juvenile resembles female; in captivity, adult male plumage acquired in about two years. Voice. Song, by both sexes, a loud series of well-spaced whistles. A common call is a harsh "chrr".
Habitat. Mesic to humid tropical forest, particularly in ravines ("ghauts") with stands of the plant *Heliconia caribaea*. Mostly between 400 m and 900 m.
Food and Feeding. Mostly insects and other arthropods, also fruits; wild individuals seen to take mangoes (*Mangifera indica*), and zoo captives ate kiwis (*Actinidia*) and papayas (*Carica*). Presumably also takes nectar. Gleans arthropods from foliage. Forages mostly in understorey, sometimes higher. Generally in pairs.
Breeding. Season Mar–Aug, depending on rainy season; sometimes two or, exceptionally, three broods. Presumably monogamous. Bag-shaped nest built by female, stitched to underside of *Heliconia caribaea* leaves, banana leaves, or palm fronds if available. Clutch 2–3 eggs, occasionally 4, creamy white to pale greenish, variably marked with reddish-brown and grey spots, two eggs laid at Jersey Zoo (UK) 23·9 × 18·3 mm and 25·1 × 17·7 mm; in captivity, incubation period 13–14 days and nestling period 14–16 days, chicks fed by both parents.
Movements. Resident.
Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species: present in Lesser Antilles EBA. Rare. Estimated population perhaps 460–590 pairs within tiny global range. Has declined greatly owing to combination of human pressure, natural catastrophes and small size of its island range. Formerly present in all main montane forests, but increasing cultivation reduced these to a few suitable patches. Series of volcanic eruptions and ashfall in Soufrière during 1995–1997 destroyed most of remaining forest, and this species is now more or less restricted to area of c. 14 km² in Centre Hills, with small numbers in South Soufrière Hills, where some thought to have survived in patch of forest covering 1–2 km²; volcano has remained active, with intermittent eruptions, ever since then. In 2001 and 2003, reduction in laying frequency and clutch size thought to have been caused by drought; excessive rainfall can have adverse impact. Main current threats appear to be high rates of nest predation by Pearly-eyed Thrashers (*Margarops fuscatus*) and by introduced rats (*Rattus*); also habitat deterioration caused by feral livestock, which eat native plants, including *Heliconia caribaea* (the oriole's preferred nesting plant), and hinder forest regeneration, with feral pig (*Sus*) population particularly destructive and spreading rapidly. A captive-breeding programme started in 1999 has achieved some success; regarded as a precautionary measure, in case the species does become extinct in the wild. Other conservation measures taken include designation of Centre Hills as a protected area, within which no development permitted. A Species Action Plan was published in 2005, and experimental rat control in Centre Hills began in 2006. A pig-eradication programme is planned.
Bibliography. Anon. (2010d), Arendt *et al.* (1999), Atkinson & Gibbons (1998), Butchart & Stattersfield (2004), Dalsgaard *et al.* (2007), Evans (1990), Garrido *et al.* (2005), Gibbons *et al.* (1998), Hilton *et al.* (2003), Hofmann *et al.* (2008a), Lovette, Rickleffs & Bermingham (1999), Owen (2001, 2003), Raffaele *et al.* (1998), Stattersfield & Capper (2000), Sturge *et al.* (2009).

54. Puerto Rican Oriole

Icterus portoricensis

French: Oriole de Porto Rico **German**: Puerto-Rico-Trupial **Spanish**: Turpial Puertorriqueño
Other common names: Greater Antillean Oriole (when treated as conspecific with *I. northropi*, *I. melanopsis* and *I. dominicensis*)

Taxonomy. *Icterus dominicensis* var. *portoricensis* H. Bryant, 1866, Puerto Rico.
Often treated as conspecific with *I. northropi*, *I. melanopsis* and *I. dominicensis*, but recent morphological and behavioural studies suggest that all of these merit full species rank. Mitochondrial DNA indicates that present species is closely related to *I. bonana*, *I. laudabilis* and *I. oberi*. Monotypic.
Distribution. Puerto Rico.
Descriptive notes. 22 cm; male 37·2– 44·9 g, female 34–38·9 g. Plumage is mostly black, with yellow lower back and rump, yellow lesser and median upperwing-coverts (forming epaulet), yellow lower belly and thigh; uppertail-coverts and rear undertail-coverts black with yellow tips; iris dark brown; bill blackish; legs grey. Sexes similar. Juvenile is olive-green above, with reddish tinge on

head, mostly dull yellow below, with rufescent wash on breast. Voice. Song, lasting c. 2 seconds, a rather high-pitched series of ascending and descending whistles, mixed with buzzes and warbles. A common call is a harsh "chk".

Habitat. Edges of forest and woodland of many types, also palm groves, parks and gardens.

Food and Feeding. Insects and other arthropods, small vertebrates, fruits and nectar. Contents of 71 stomachs were mostly invertebrates, particularly beetles (Coleoptera), Orthoptera, earwigs (Dermaptera) and spiders (Araneae). Vertebrates taken include small *Anolis* lizards and frogs. Visits *Erythrina* flowers. Nestling diet includes some fruits. Forages mostly on trees, gleaning from leaves and epiphytes. Usually occurs in pairs or in family groups.

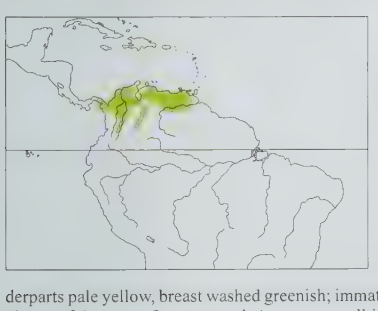
Breeding. Season Mar–Jun. Probably monogamous. Solitary breeder. Nest, apparently built by female alone, variable in size and complexity, usually attached or stitched to underside of palm frond or in *Heliconia* or banana leaves; one was large and elaborate, c. 4 m above ground, a hanging mat firmly attached to a coconut palm (*Cocos nucifera*) frond by four straps, each one looped around 20–24 palm pinnae (leaflets) on each side of midrib, entire oblong structure plus straps measured 77·5 × 71·2 cm, internal nest-chamber 10·2 cm in diameter and 6·3 cm deep, the whole made from fibres from same palm, internal cup sparsely lined with *Tillandsia* stems; another nest was simpler and smaller, a hanging basket stitched at three points to underside of fan-shaped frond of royal palm (*Roystonea*). Clutch 2–3 eggs, white to pale bluish-white with sparse spots in shades of grey and brown, mean dimensions 24·1 × 17·5 mm; incubation apparently by female only, no information on duration; both sexes feed chicks, nestling period c. 14 days; male guards and defends nest. Nests frequently parasitized by *Molothrus bonariensis*: studies in 1980s showed that almost all nests in coastal areas were parasitized, but of 28 nests inland 11 (39%) did not suffer parasitism; in parasitized nests, only 14% of host eggs produced fledglings. Individuals may breed in immature plumage.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. A fairly common to common species, found even in modified habitats.

Bibliography. Arendt *et al.* (1999), Garrido *et al.* (2005), Lovette, Rickleffs & Bermingham (1999), Omland *et al.* (1999), Pérez-Rivera (1986), Raffaele *et al.* (1998), Spaulding (1937), Sturge *et al.* (2009), Wetmore (1927), Wiley (1985).

55. Orange-crowned Oriole



Icterus auricapillus

French: Oriole à tête d'or **German**: Orangekopftrupial **Spanish**: Turpial Coroninaranja

Taxonomy. *Icterus auricapillus* Cassin, 1848, Santa Marta, Colombia.

Recent DNA data indicate close relationship with *I. dominicensis*, *I. bonana*, *I. laudabilis*, *I. oberi* and *I. portoricensis*. Monotypic.

Distribution. E Panama (E from Panamá and Darién) E across N Colombia (S to Huila and N Meta) and Venezuela (E to Sucre and Monagas, S to N Bolívar).

Descriptive notes. 18 cm; male average 33·1 g, female average 32 g. Has forehead, area around eye, lores, throat and breast black, crown, nape and side of head orange-red; mantle and upper back black, lower back and rump yellow, rearmost uppertail-coverts black with narrow yellow terminal edge, tail black; upperwing black, lesser and median coverts yellow; underparts below breast yellow; iris brown; bill black; legs grey. Sexes similar. Juvenile is paler than adult, face orange-yellow, crown and upperparts olive, rump washed yellow, wings and tail dusky, greater upperwing-coverts tipped yellowish (pale wingbar), throat and underparts pale yellow, breast washed greenish; immature like adult, but duller. Voice. Song a whistled phrase of 4 notes, often repeated. A common call is a sharp "cheet". Possibly mimics other birds.

Habitat. Mesic to humid forest edges, riparian forest, cultivated land and pastures with trees; to 1900 m.

Food and Feeding. Insects and other arthropods, also fruits and nectar. Visits blooming trees of *Erythrina poepiggiana*, also flowers of *Bauhinia*. Forages in canopy. Usually in pairs or in small family groups; joins other orioles, e.g. *I. galbula* in Colombia.

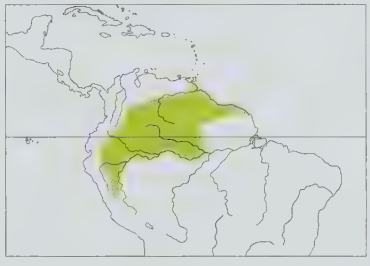
Breeding. Season Apr–Jun in N Colombia (Santa Marta) and Sept in E Venezuela (N Bolívar). Three nests from N Colombia (Santa Marta) described as "of the usual *Icterus* type", woven mostly from palm fibres, uniform in appearance, all stitched to underside of and partially covered by palm frond, some loose fibres hanging from nest bottom like drapery; a nest from Venezuela was made from blackish fibres (possibly of *Marasmius* fungus), maximum external length 40 cm, stitched to underside of banana leaf (*Musa*) 2 m above ground. Clutch 2 eggs, whitish with brownish and pale purple spots, one measured c. 22·7 × 15 mm. Parasitized by *Molothrus bonariensis*. No further information.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Fairly common to uncommon. Common in Panama; rarer or local in Venezuela. Found in Cueva del Guácharo National Park, in Venezuela.

Bibliography. Boggs (1961), Darlington (1931), Hilty (2003), Jaramillo & Burke (1999), Miller (1947), Navarro *et al.* (2010), Restall *et al.* (2006), Ridgely & Tudor (1989), Sturge *et al.* (2009), Todd & Carriker (1922), Wetmore *et al.* (1984).

56. Moriche Oriole



Icterus chrysocephalus

French: Oriole des moriches **German**: Goldkappentrupial **Spanish**: Turpial Moriche

Taxonomy. *O.*[*riolus*] *chrysocephalus* Linnaeus, 1766, Cayenne, French Guiana.

Closely related to *I. cayanensis*, and often treated as conspecific with it and with *I. pyrrhopterus*. Mitochondrial DNA data reveal small divergence (0·6%) between present species and *I. cayanensis*; intermediate or hybrid individuals reported mostly from Suriname, but the two do not hybridize in areas of range overlap in Guyana and Brazil, nor in Sipaliwini area of C Suriname; hybridization possibly occurs locally when conspecifics scarce, but further study needed. Monotypic.

Distribution. S & E Venezuela (S from E Apure, Sucre, Monagas and Delta Amacuro), Guyana, N & C Suriname and N French Guiana S in Amazonia to E Colombia, E Ecuador, N Peru (Loreto) and NW Brazil (Roraima and Amazonas).

Descriptive notes. 22 cm; male average 43·5 g, female average 42·1 g. Plumage is mostly black, with golden-yellow crown, nape, rump, lesser and median upperwing-coverts (epaulet) and thigh; underwing-coverts-lemon yellow, with inner webs of flight-feathers edged white; iris brown; bill blackish; legs leaden grey to blackish. Sexes similar. Juvenile resembles adult, but plumage blackish-brown, yellow areas duller yellow, greater upperwing-coverts narrowly tipped yellow (indistinct wingbar). Voice. Song a slow series of ascending and descending notes, usually grouped in phrases of 2–3 notes. Call a mewing sound. Mimics calls of other birds, e.g. alarm call of Smooth-billed Ani (*Crotophaga ani*).

Habitat. Found mostly in groves of moriche palm (*Mauritia flexuosa*) growing along marshes and channels (*caños*); also forest canopy and edges, gallery forest, trees in clearings, and sometimes in parks and gardens. Lowlands; to 1100 m in Colombia.

Food and Feeding. Insects, including beetles (Coleoptera), also other arthropods, mainly spiders (Araneae); also fruits and nectar. Nestling diet mostly insects. Forages in canopy and at edges of trees, often high up in forest. Gleans arthropods from palm fronds and other foliage. Often visits large forest flowers to obtain nectar. Usually singly or in pairs; sometimes joins mixed-species foraging flocks in canopy.

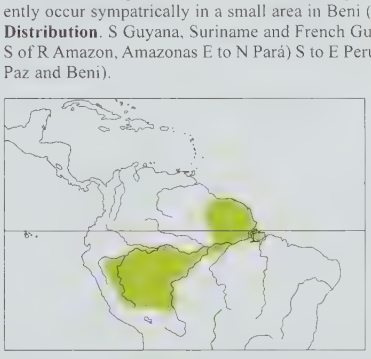
Breeding. Season Jul–Jan in Brazil (Amazonas) and Sept–Feb in Suriname; pair with fledgling in May in Guyana. Probably monogamous. Solitary breeder. Nest apparently built by both sexes, mostly in moriche palm, a shallow basket with external diameter 7–10 cm, external depth c. 9·5 cm, woven from plant fibres (mostly those of supporting palm) and often lined with fine fibres, in Brazil two nests stitched to underside of dead leaves of moriche palm, one c. 2·5 m above ground, and similar reports from Venezuela; in Guyana five successive basket-like nests built by a single pair under fronds of a royal palm (*Roystonea*), stitched to several supporting "leaflets", entrance facing palm trunk, one oblong nest measured 12 cm in external length and 6·5 cm in external depth. Clutch 2 eggs, creamy or bluish-white, spotted and blotched in brown, mean dimensions 26 × 17·7 mm; chicks fed by both sexes. Reported as host of *Molothrus bonariensis*. No further information available.

Movements. Apparently resident.

Status and Conservation. Not assessed. Locally fairly common to uncommon. Relatively scarce or localized in Venezuela. Reports from Trinidad believed to involve escaped cagebirds. Frequently trapped for exploitation as a cagebird, particularly around rural villages.

Bibliography. Areta (2009b), Beebe (1909), Belcher & Smooker (1937), D'Horta *et al.* (2008), Friedmann & Kiff (1985), Haverschmidt (1966a, 1968), Haverschmidt & Mees (1994), Herklots (1961), Hilty (2003), Hilty & Brown (1986), McCarthy (2006), Oniki & Willis (1983), Restall *et al.* (2006), Robbins *et al.* (2007), Schönwetter & Meise (1981, 1982).

57. Epaulet Oriole



Icterus cayanensis

French: Oriole à épaulettes **German**: Epaulettentrupial **Spanish**: Turpial Boyerito

Taxonomy. *O.*[*riolus*] *cayanensis* Linnaeus, 1766, French Guiana.

Closely related to *I. chrysocephalus*, and often treated as conspecific with it; mitochondrial DNA data reveal small divergence (0·6%) between the two, and intermediate or hybrid individuals reported mostly from Suriname, but no known hybridization in areas of range overlap in Guyana and Brazil, nor in Sipaliwini area of C Suriname. Often treated as conspecific also with *I. pyrrhopterus*, but differs in larger size, more curved bill shape, habitat selection and behaviour; the two apparently occur sympatrically in a small area in Beni (Bolivia) without interbreeding. Monotypic.

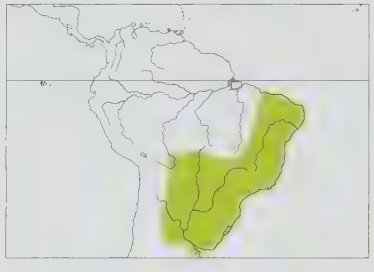
Distribution. S Guyana, Suriname and French Guiana, and N Brazil (S Roraima E to Amapá and, S of R Amazon, Amazonas E to N Pará) S to E Peru (Loreto S to Madre de Dios) and N Bolivia (La Paz and Beni).

Descriptive notes. c. 22 cm; male average 46 g, one female 42 g. Plumage is entirely black, except for yellow patch (epaulet) at bend of wing (lesser and median upperwing-coverts); some individuals (mostly in Peru) show some yellow in otherwise black thigh; iris deep red-brown; bill blackish; legs leaden grey to blackish. Sexes similar. Juvenile is like adult, including yellowish epaulet, but plumage tinged brown. Voice. Song not very musical, a varied series of ascending and descending notes, also mixing clicks and buzzes, with main frequency range 1·5–7·5 kHz. A common call is a short nasal note.

Habitat. Canopy and edges of primary and tall secondary forest, clearings with large trees, gallery forest, swamp-forest; seems less palm-dependent than *I. chrysocephalus*. Lowlands up to 1200 m.

Food and Feeding. Little detailed information. Feeds on insects, other arthropods, also fruits and nectar. Visits flowering *Erythrina* trees to obtain nectar. Usually forages in canopy, but in open areas may descend to low bushes and even to ground in search of insects. Generally singly and in pairs; often in mixed-species foraging flocks.

Breeding. Season Aug–Oct in French Guiana. Monogamous. Solitary breeder. Few nests found; nest built by both sexes, a hammock-like basket c. 40 cm long, roughly oblong in shape and with entrance at each end, made from tough, wire-like black fungal rhizomorphs of *Marasmius* and *Marasmiellus*, internal cavity 20–25 cm long, stitched at four points to underside of banana leaf c. 6 m above ground or to underside of leaf of coconut palm (*Cocos nucifera*); structure resembles



most elaborate nests built by *I. portoricensis*. Clutch probably 2–3 eggs; one nest contained three feathered chicks; both parents feed nestlings and both defend nest. No other information.
Movements. Apparently sedentary.
Status and Conservation. Not assessed. Not well known. Appears to be uncommon or local throughout its reasonably extensive range.
Bibliography. D'Horta *et al.* (2008), Fraga (1987a), Haverschmidt (1966a, 1968), Ingels *et al.* (2003), Jaramillo & Burke (1999), McCarthy (2006), Niethammer (1956), Restall *et al.* (2006), Robbins *et al.* (2007), Santos *et al.* (2010), Willis & Oniki (2007).

58. Variable Oriole

Icterus pyrrhopterus

French: Oriole variable **German**: Feuerflügeltrupial **Spanish**: Turpial Variable
Other common names: Yellow-shouldered Oriole

Taxonomy. *Agelaius pyrrhopterus* Vieillot, 1819, Paraguay.
Often treated as conspecific with *I. chrysocephalus* and/or *I. cayanensis*. Differs from latter in size and bill shape, broader habitat selection and more active behaviour; the two apparently occur sympatrically in a small area in Beni (Bolivia) without interbreeding. Races intergrade; *valenciobuenoi* a variable form, connecting *tibialis* and nominate race, and sometimes subsumed in one or the other of these (a few individuals with characters of *valenciobuenoi* can be found in nominate populations, e.g. in NE Argentina). Four subspecies recognized.
Subspecies and Distribution.
I. p. tibialis Swainson, 1838 – E Brazil from Maranhão and Ceará S to Río de Janeiro.
I. p. periporphyrus (Bonaparte, 1850) – EC Bolivia (Beni, Cochabamba and N Santa Cruz) and adjacent SC Brazil (Mato Grosso).
I. p. valenciobuenoi H. von Ihering, 1902 – SE Brazil (Goias, Minas Gerais, São Paulo, Paraná and Santa Catarina).
I. p. pyrrhopterus (Vieillot, 1819) – SE Bolivia (S Santa Cruz S to Tarija), Paraguay, S Brazil (Mato Grosso do Sul and Rio Grande do Sul), N & NE Argentina (S to San Juan, San Luis, La Pampa and Buenos Aires) and Uruguay.

Descriptive notes. c. 20 cm; male average 33·3 g, female average 30·4 g (nominate, Argentina). A small, long-tailed oriole with slender straight bill. Nominate race is entirely black, except for dark chestnut epaulet (lesser and median upperwing-coverts) and pale grey underwing (in flight, latter flashing when seen from below); iris reddish-tawmy to dark red-brown; bill blackish; legs leaden grey to blackish. Sexes similar. Juvenile has black colour more dusky, epaulet somewhat paler. Race *tibialis* has epaulet yellow, also yellow thighs; *periporphyrus* has epaulet paler chestnut and larger than that of nominate; *valenciobuenoi* resembles nominate, but epaulet tawny to yellow, but quite variable. Voice. Song rather fast, variable, pleasant, but not too musical; sings rather infrequently in Argentina. A common call is a sharp "keet". Imitates several other bird species, including Roadside Hawk (*Buteo magnirostris*) and alarm calls of several non-passerines, e.g. Guira Cuckoo (*Guira guira*) and Smooth-billed Ani (*Crotophaga ani*), and passerines, e.g. Great Kiskadee (*Pitangus sulphuratus*) and Rufous Hornero (*Furnarius rufus*). In captivity, may copy calls of nearby caged parrots (Psittacidae) and also canaries (*Serinus*).
Habitat. Forest edges and clearings, palm savannas, palm groves, sometimes in clumps of flowering *Thalia* in swamps, also mesic to dry *chaco* and *caatinga* woodlands; also parks and gardens, and street trees in small towns. Lowlands and hills, nominate race usually to 1700 m; rarely, to 2500 m in Bolivia.
Food and Feeding. Insects, other arthropods, nectar and fruits. Insects in stomach contents include stink-bugs (Pentatomidae), cockroaches (Blattodea), termites (Isoptera) and beetles (of families Curculionidae, Chrysomelidae and Scarabaeidae). Obtains nectar from flowers of *Erythrina cristagalli*, *Erythrina dominguezii*, *Inga uruguensis*, *Ceiba*, *Thalia*, and the vine *Combretum fruticosum*; usually tears or punctures tubular flowers (e.g. *Tabebuia* and other Bignoniaceae) to obtain nectar; in late austral winter (Aug), commonly visits blooming *Tabebuia* trees in Chaco region. Eats sweet, fleshy petals of the small myrtaceous tree *Myrrhinium atropurpureum*, and is a potential pollinator of this plant. Also eats fruits such as guava (*Psidium guajava*) and those of *Urera baccifera* and *Cordia curassavica*. Almost exclusively arboreal, often hanging upside-down while feeding. Forages in pairs and in family groups, also in flocks of up to 30 individuals. In non-breeding season frequently in mixed-species foraging flocks, particularly with tyrant-flycatchers, e.g. Suiriri Flycatcher (*Suiriri suiriri*), or with other icterids, e.g. *I. croconotus*, *Cassiculus melanicterus* and *Agelaioides badius*.
Breeding. Season Oct–Jan in Argentina. Probably monogamous. Solitary breeder. Nest a shallow basket woven from fine plant fibres, often palm fibres, sometimes also horsehair (fungal rhizomorphs of *Marasmius* not reported in Argentinian nests), external diameter 9–10 cm, external depth 8–9 cm, stitched to underside of palm frond, often fan-leaved palm, either wild (e.g. *Copernicia*, *Trithrinax*) or cultivated (*Washingtonia*, *Roystonea*), or of leaf of tree; many species used, especially banana (*Musa*), *Thalia*, and other wide-leaved monocotyledons, and found nesting in ornamental *Dracaena* and *Cordyline* plants growing in pots on veranda of rural house in Argentina; other nests built inside mistletoe (Loranthaceae) clumps or epiphytic *Tillandsia*, and one was stitched to inner wall of unfinished nest of *Cacicus haemorrhous*. Clutch 3–4 eggs, white to pale bluish-grey, marked with spots and lines in hues of brown, blackish and grey, mean dimensions (nominate race) 26 × 16·3 mm; incubation period 14 days; chicks fed by both parents, nestling period 14–15 days; both parents defend nest. Nests regularly parasitized by *Molothrus bonariensis*; in sample of 27 nests in Argentina (Formosa, Corrientes, Santa Fe), ten contained one or two eggs of this parasite.
Movements. Apparently resident. Short local movements to visit flowering or fruiting trees.
Status and Conservation. Not globally threatened. Locally common. Has extensive range in which numbers increasing. Found in modified environments, even in gardens and towns, and is expanding its range in C & W Argentina.

Genus *NESOPSAR* P. L. Sclater, 1859

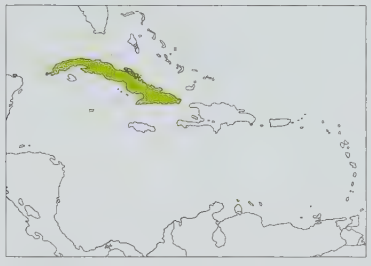
59. **Jamaican Blackbird**

Nesopsar nigerrimus

French: Carouge de Jamaïque **German**: Bromelienstärling **Spanish**: Zanate Jamaicano

Taxonomy. [*Icterus*] *nigerrimus* Osburn, 1859, lower mountains of Jamaica.
One of the most specialized icterids; analyses of mitochondrial DNA indicate that it is close to ancestral stem of quiscaline group, but lacks close living relatives. Previous speculation had suggested possible affinity with *Icterus* or *Agelaius*. Monotypic.
Distribution. Jamaica.

Descriptive notes. 18 cm; average 39 g. All-dark icterid with slender sharp bill and relatively short tail and legs. Plumage is entirely black with slight blue gloss; iris brown; bill and legs black. Sexes similar. Juvenile resembles adult, but plumage is heavily tinged brown and lacks gloss. Voice. Rather noisy. Song, delivered by both sexes, is a quick warble followed by 3–5 nasal buzzes, covering a wide frequency range; song also typically uttered during aerial display. A common call is a sharp "chek".
Habitat. Wet mountain forest in areas with high rainfall and frequent mists, mostly above 570 m. Requires forest with abundant epiphytes, particularly bromeliads (of genera *Guzmania*, *Vriesia*, *Tillandsia*, *Hohenbergia* and *Tecophyllum*) and *Phyllogonium* mosses, and with tree-ferns. Found also in wet limestone forest in karst formations, particularly in Cockpit Country. Absent or rare in drier sclerophyll forest on windy slopes and ridges. To 2200 m; down to 210 m in non-breeding season.
Food and Feeding. Food mostly insects, including beetles (Coleoptera), orthopterans and lepidopteran caterpillars, and other invertebrates, e.g. snails (Gastropoda); also small vertebrates such as tree-frogs (*Hyla*) and small *Anolis* lizards, and reported as feeding on egg of a lizard; takes berries of *Alchornea latifolia*. Forages in trees, usually those covered with epiphytic bromeliads or *Phyllogonium* moss, usually 3–12 m above ground, rarely up to 18 m. Commonly alights and climbs up vertical trunks and main branches in manner of a woodcreeper (Dendrocolaptidae). Finds prey by inserting bill into bromeliads and moss and gaping, even tearing plant material. Spends c. 46–58% of foraging time in searching among epiphytes. Sometimes pecks into rotten wood. Also climbs up tree-ferns, searching in dead fronds (14–18% of foraging time in several studies). Rarely, reported as climbing roadside banks. Found in territorial pairs and in family groups.
Breeding. Season May–Jul. Monogamous. Territorial, solitary breeder; diameter of eleven territories 160–370 m, mean 281 m. Commonly performs aerial display, flying above canopy with slow wingstrokes while singing. Nest built by female, a bulky open cup made mostly from epiphytic orchids and rootlets, placed at medium height (mostly 6–11 m) usually on near-horizontal section of main trunk of forest tree, commonly beneath an epiphytic bromeliad. Clutch 2 eggs, white with few spots and scrawls; incubation by female, starting with second egg, period 13–15 days; chicks fed by both parents, no information on duration of nestling period; both parents defend nest; family group persists for at least two months after young fledge.
Movements. Resident; some individuals descend to 210 m in non-breeding season.
Status and Conservation. ENDANGERED. Restricted-range species: present in Jamaica EBA. Uncommon. Because of its small global range, its strict habitat requirements and its specialized foraging habits, this is a naturally scarce species. Total population thought to lie within range 2500–10,000 individuals. Formerly widespread; now locally distributed, and found mainly in Cockpit Country (in WC Jamaica), in hills in C Jamaica, and in Blue and John Crow Mts (in E Jamaica). Wet montane forest is a habitat seriously threatened by human activities, including bauxite-mining, commercial planting of exotic trees e.g. pines (*Pinus*) and coffee plantations, and fires; this icterid has probably suffered greatly from removal of mature native trees, as these support the large bromeliads in which it forages. Significant population remains in Blue and John Crow Mountains National Park (covering more than 800 km²), part of a network of protected areas with at least 40 forest reserves. Management of reserves, however, is poor and enforcement of regulations weak; habitat destruction continues, and long-term security of reserves by no means assured.
Bibliography. Anon. (2010d), Butchart & Stattersfield (2004), Cruz (1978), Hardy *et al.* (1998), Lack (1976), Raffaele *et al.* (1998), Stattersfield & Capper (2000), Wiley & Cruz (1980).



Genus *PTILOXENA* Chapman, 1892

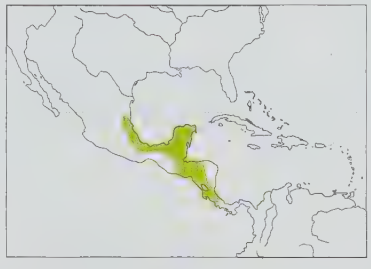
60. **Cuban Blackbird**

Ptiloxena atroviolacea

French: Quiscale violet **German**: Kubastärling **Spanish**: Zanate Cubano

Taxonomy. *Quiscalus atroviolaceus* d'Orbigny, 1839, Cuba.
Genus often subsumed in *Dives*, but distinctive skeletal morphology, song and nest-site choice indicate that a separate, monotypic genus is appropriate. No DNA data available, but absence from I of Pines (old reports erroneous) suggests poor dispersal capabilities and presumably a high genetic distinctiveness. Monotypic.
Distribution. Cuba.
Descriptive notes. 25–28 cm; male 85–94 g, female 72–80 g. Medium-sized icterid with square-shaped tail and relatively short bill. Plumage is black overall, with strong blue and purple iridescence on body, and greenish-blue gloss on wing (plumage reflects ultraviolet in several patches); iris dark brown; bill and legs black. Distinguished from similar male *Molothrus bonariensis* mainly by much larger size. Sexes similar, female slightly duller than male. Juvenile is like adult but much duller, brownish-black without gloss. Voice. Song varied, probably by both sexes, a mix of musical notes and some nasal sounds. Musical "twee-o" and "twee-te-to" calls.

Habitat. Open woodlands, agricultural land, parks, gardens, urban parks, villages. Lowlands to medium elevations.
Food and Feeding. Almost omnivorous; feeds on arthropods, small vertebrates, seeds, fruits and nectar. Forages mostly on ground; sometimes follows grazing cattle. Found in pairs and in small flocks; sometimes joins other icterids, such as *Quiscalus niger* or *Agelaius humeralis*, particularly at roosts.
Breeding. Season Apr–Jul; fledglings reported May–Aug. Probably monogamous, but no details available. Solitary nester. Nest built by both sexes, cup-shaped, made variously from fig (*Ficus*) rootlets, hair and feathers, lined with finer material (e.g. fibres from a species of Araceae), one had external diameter 17·5 cm and internal diameter 8·5 cm, depth 3 cm, placed in enclosed space such as base of palm frond, often of Cuban royal palm (*Roystonea regia*), sometimes in coconut (*Cocos nucifera*) or other unidentified palm, or in clump of epiphytic bromeliads, or in open cavity in dead tree; sometimes in building, e.g. three nests built on beam below roof of a sentry box, and one nest found 2·8 m up inside building near Havana. Clutch 3–4 eggs, greyish-white with dark brown spots, mostly at large end, mean dimensions c. 29 × 19 mm; estimated incubation period 12 days; chicks fed by both parents, no information on duration of nestling period.
Movements. Resident.
Status and Conservation. Not globally threatened. Common, and widespread. A rather abundant species that tolerates habitat modification, living and breeding even in towns and cities. Confined to mainland Cuba, and absent from cays and outlying islands; reports of this species from I of Pines erroneous, apparently referable to misidentified *Quiscalus niger*. No known threats, and not reported as ¤ *Molothrus bonariensis* host.
Bibliography. Arendt *et al.* (2004), Balát & González (1982), Garrido & Kirkconnell (2000), Godínez & Blanco (1993), Gundlach (1876), Hardy *et al.* (1998), Raffaele *et al.* (1998), Valdés (1984), Webster (2003).



Genus *DIVES* Cassin, 1867

61. **Melodious Blackbird**

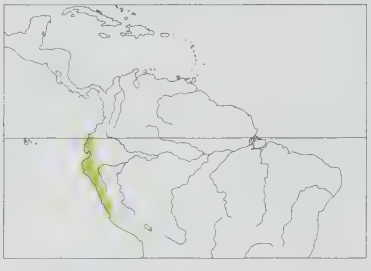
Dives dives

French: Quiscale chanteur **German**: Trauerstärling **Spanish**: Zanate Cantor
Other common names: Sumichrast's/Singing Blackbird

Taxonomy. *Icterus dives* W. Deppe, 1830, Mexico.
According to molecular data, genus is one of the more ancestral members of the quiscaline group. This species and *D. warczewiczi* may form a superspecies, and previously treated as conspecific. Monotypic.
Distribution. NE Mexico (S Tamaulipas) S in lowlands of Caribbean coast, and from Guatemala also along Pacific coast, to Costa Rica.

Descriptive notes. Male 25·5 cm, 98·3–102 g; female 23 cm, 83·4–95·9 g. Medium-sized all-dark icterid with long tail. Plumage is wholly black, with blue and purple iridescence; iris dark brown; bill and legs black. Sexes similar, female smaller than male. Juvenile is duller than adult, plumage brownish-black and lacking gloss. Voice. Song, by both sexes, often in duet, loud and musical, a mix of mellow whistles and warbles with sudden changes in pitch. Flight call a metallic "tink-tink-tink"; a common call is a loud "cheep".
Habitat. Open pine woodland (mostly of the native pines *Pinus caribaea* and *Pinus oocarpa*), clearings in forest, shrubby riverbanks, coffee plantations, pastures with scattered trees, also parks, gardens and towns. Lowlands to 2000 m.
Food and Feeding. Quite omnivorous: insects and other arthropods, small vertebrates, fruit, nectar of e.g. balsa trees (*Ochroma pyramidale*) and seeds, including seeds of cultivated maize (*Zea mays*). Picks ticks (Ixodoidea) and other arthropod parasites from cattle. Feeds on fruits of several native plant species, such as *Clidemia rubra*, *Miconia albicans*, *Stemmadenia*, *Ficus padifolia*, *Ehretia tinifolia* and *Talisia olivaeformis*. Forages mostly on ground, where it walks with head-bobbing movements; also in trees up to canopy level. Uses much gaping to extract prey from pine cones, bromeliads, rolled leaves and other substrates. Found mostly in pairs and in family groups, but flocks of at least 100 individuals reported. Associates with other icterids, such as *Quiscalus* and *Molothrus*, and with Groove-billed Anis (*Crotophaga sulcirostris*).
Breeding. Season Apr–May in Belize and Guatemala. Monogamous. Solitary, territorial breeder. Nest built by both sexes, an open cup of diverse plant material, such as strips of banana leaves or dead pine needles, often mixed or plastered with mud, and lined with finer plant fibres (rootlets, grass), the structure substantial (like nest of *Quiscalus*) or rather flimsy, placed 3–7 m above ground in tree, sometimes partially attached by fibres to branches or twigs. Clutch 3–4 eggs, pale blue with scattered dots and spots in brownish to black, mean dimensions 28·4 × 20·4 mm; incubation by female, chicks fed by both sexes, no information on duration of incubation and nestling periods.

On following pages: 62. Scrub Blackbird (*Dives warczewiczi*); 63. Common Grackle (*Quiscalus quiscula*); 64. Nicaraguan Grackle (*Quiscalus nicaraguensis*); 65. Carib Grackle (*Quiscalus lugubris*); 66. Greater Antillean Grackle (*Quiscalus niger*); 67. Great-tailed Grackle (*Quiscalus mexicanus*); 68. Boat-tailed Grackle (*Quiscalus major*).



Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common to fairly common throughout range. Invades modified habitats. As a result of deforestation, has expanded range S, reaching Costa Rica in 1980s (first records 1988) and, more recently, Panama. No known threats; not reported as a host of sympatric *Molothrus aeneus*, which occupies same habitats as present species.
Bibliography. Dickerman (2007), Feduccia (1976), Howell & Webb (1995), Jaramillo & Burke (1999), Kantak (1979), Orians (1983, 1985a), Russell (1964), Sánchez *et al.* (1998), Schönwetter & Meise (1981, 1982), Skutch (1954, 1996), Stiles (1988), Stiles & Skutch (1989), Thurber *et al.* (1987).

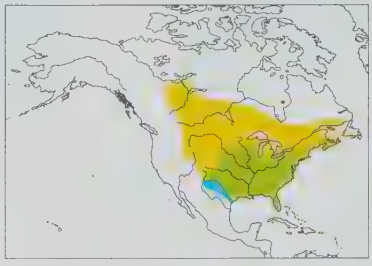
62. Scrub Blackbird

Dives warczewiczi

French: Quiscale buissonnier **German**: Buschstärling **Spanish**: Zanate Matorralero
Other common names: Peruvian/Kalinowski's/Coastal Blackbird (*kalinowskii*)

Taxonomy. *Lampropsar Warczewiczi* Cabanis, 1861, Peru.
According to molecular data, genus is one of the more ancestral members of the quiscaline group. This species and *D. dives* may form a superspecies, and previously treated as conspecific. Races intergrade in NW Peru (Cajamarca and La Libertad). Two subspecies recognized.
Subspecies and Distribution.
D. w. warczewiczi (Cabanis, 1861) – W Ecuador (from S Esmeraldas and N Pichincha) S to NW Peru (Tumbes S to La Libertad).
D. w. kalinowskii Berlepsch & Stolzmann, 1892 – coastal plain and foothills of W Peru from La Libertad S, extending inland in Cajamarca (upper R Marañón) and Huancavelica, to Ica.

Descriptive notes. c. 21·5 cm (nominate); male average 85·5 g and female average 84 g (nominate), male 110 g (*kalinowskii*). Medium-sized all-dark icterid with long tail. Nominate race is wholly black, with a blue to green iridescence; iris dark brown; bill and legs black. Sexes similar. Juvenile is duller than adult, with plumage blackish-brown and mostly unglossed, blackest and with slight iridescence on head, mantle and breast. Race *kalinowskii* is much larger than nominate, with longer bill, and has violaceous iridescence. Voice. Song, usually by both sexes in duet, a rather pleasant mixture of warbles, trills and whistles, mixed with chattering and buzzing notes. Sharp "teeeew" call in flight.
Habitat. Xeric open woodland and scrub in lowlands and foothills, agricultural areas, clearings, fruit orchards, parks and gardens, and residential areas, even in large cities (e.g. Lima, in Peru). Along almost rainless coast of Peru, found mostly around oases, riparian areas or irrigated farmland. Nominate race to 2100 m, rarely at 2800 m; *kalinowskii* to 3000 m.
Food and Feeding. Few detailed data. Diet presumably insects and other arthropods, also small vertebrates, fruits and seeds; reported as catching a lizard. Stomach contents include insects, fruit pulp such as cultivated mangoes (*Mangifera indica*), and seeds. Forages mostly on the ground. Often in pairs.
Breeding. Season Feb–May; a food-begging juvenile in Jun in Lambayeque (Peru). Presumably monogamous. Apparently less territorial than *D. dives*. Nest in Ecuador a shallow cup made from sticks, weeds, grass and pieces of banana leaves, with some cementing mud, mean external diameter 14·3 cm and height 8·4 cm, internal diameter 9·3 cm and depth 5·1 cm, placed 5–6 m above ground in tree, including *Prosopis juliflora*, *Cordia lutea* and a lemon tree (of seven nests, five along dry riverbed and two in an orchard); two nests found high in eucalypt (*Eucalyptus*) trees in agricultural area in Peru. Clutch 2–3 eggs, mean 2·8, pale blue with scattered dots and spots in brownish to black, mean dimensions 27·5 × 19·2 mm; no information on incubation period; nestling period 12 days. Nests parasitized by *Molothrus bonariensis*s, and observed to feed fledgling of latter.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Common and numerous. Tolerates habitat modifications. Appears to be expanding its range in both Peru and Ecuador.
Bibliography. Friedmann & Kiff (1985), Jaramillo & Burke (1999), Knowlton (2010), Orians (1983), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schönwetter & Meise (1981, 1982), Schulenberg & Parker (1981), Schulenberg *et al.* (2010).



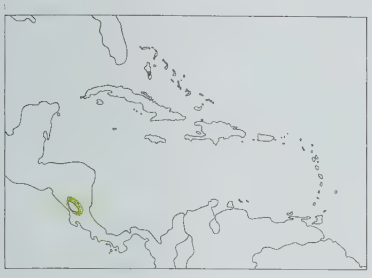
Genus *QUISCALUS* Vieillot, 1816

63. Common Grackle

Quiscalus quiscula

French: Quiscale bronzé **German**: Purpurgrackel **Spanish**: Zanate Común
Other common names: Florida Grackle (*quiscula*); Bronzed Grackle (*versicolor*); Purple Grackle (*stonei*)

Taxonomy. *G.[racula] Quiscula* Linnaeus, 1758, coast of South Carolina, USA.
According to DNA data, this species is ancestral to other members of genus. In the past, races *versicolor* and *stonei* were sometimes treated as two separate species. Further, these two races intergrade in E USA from Connecticut S to Louisiana; intermediate populations described as a distinct race, *ridgwayi*, but such treatment of this variable form unwarranted. Three subspecies recognized.
Subspecies and Distribution.
Q. q. versicolor Vieillot, 1819 – breeds in S Canada from E British Columbia E to S Quebec and Newfoundland, S in USA (E of Rocky Mts and W of Appalachians) to C Texas and W Mississippi; winters S to S Texas and E to South Carolina.
Q. q. stonei Chapman, 1935 – E USA from New Jersey and Pennsylvania S (mostly along Appalachians) to inland Louisiana, Alabama, Georgia and South Carolina.
Q. q. quiscula (Linnaeus, 1758) – SE USA on Atlantic and Gulf coasts from S North Carolina S to Louisiana and S Florida (including Florida Keys).



Descriptive notes. Male 27·2 cm, average 119·6 g; female 26 cm, average 92·2 g. Medium-sized icterid with long wedge-shaped tail; plumage entirely black and glossy. Male nominate race has strong purple gloss on head, dark green gloss on back, purple-blue iridescence on belly, and blue-green gloss on tail (held in keel-like shape); iris pale yellow; bill and legs black. Female resembles male, but smaller, less glossy, and with shorter tail (held in "normal-looking" position). Juvenile is like female, but plumage duller and distinctly browner, with dark eyes. Races differ mainly in colour of iridescence: *versicolor* has gloss on head blue-green (creating visible hood), greenish-bronze on back and belly, and purplish on tail; *stonei* is intermediate between previous and nominate, iridescence on head purple or green, on back and belly purple, on tail usually blue-green. Voice. Male song a rasping "tzu-dee", likened to sound made by a rusty gate; each male seems to have just one song type. Call a harsh, dry "kerrr", also a thin "zweeej"; low "kek" in flight.
Habitat. Original habitat probably groves of eastern cottonwoods (*Populus deltoides*), American sycamores (*Platanus occidentalis*), and other trees near swamps and watercourses. Nowadays found also in wide variety of open areas with scattered trees, particularly groves of coniferous trees, including rural areas, residential areas, city parks, and swamps with willows (*Salix*) and other trees. Mostly in lowlands and foothills.
Food and Feeding. Almost omnivorous, but rarely consumes fruits. Contents of 2346 stomachs were 30% animal food, 70% plant food, animal food peaking in spring and summer. Insects, mostly beetles (Coleoptera), grasshoppers (Orthoptera) and caterpillars (Lepidoptera) predominate in diet. Other animal food includes spiders (Araneae) and crayfish (Crustacea), and even picks parasitic leeches (Hirudinea) from legs of map turtles (*Graptemys*); takes many small vertebrates, particularly aquatic species such as fish and frogs; preys on adults, eggs and chicks of small birds, and even catches mice (Muridae). Plant food includes cultivated grains, mostly maize (*Zea mays*) and rice. In towns consumes household food scraps and garbage. Nestling diet mostly arthropods, with small percentage of fish and other vertebrates. Forages on ground and in trees and bushes; opportunistic, captures fish, tadpoles and adult frogs in shallow water by wading or during over-water flights. Often forages in flocks; winter roosts can contain thousands of individuals, often mixed with other icterids and Common Starlings (*Sturnus vulgaris*).
Breeding. Season Mar–Jul; usually single-brooded. Mostly monogamous, sometimes successively polygynous. Nests solitarily, also in loose colonies usually of 10–18 pairs, exceptionally up to 200 pairs; territorial defence limited to small area around nest-site. Male has perched courtship display in which it lowers head, erects body feathers, and spreads wings and tail while singing ("Song Spread" or "Ruff-out"); female chooses nest-site. Nest built mostly by female, a bulky cup with external diameter 16·5–22 cm, external depth 8–22 cm, made from stems, leaves and fine grasses, man-made materials such as paper, string and the like incorporated, cup cemented with mud and lined with fine grasses or horsehair, placed at variable height in tree or other vegetation, most nests (62·5% in various studies) in conifer (evergreen conifers offer better cover for earlier breeders), sometimes in deciduous tree or shrub; more rarely used sites include man-made structures, emergent aquatic plants, holes in trees and logs, and crevices in cliffs. Clutch 4–5 eggs, rarely 6 or 7, light blue to pearl-grey with blackish-brown scrawls, some resembling spots, mean dimensions 28·8 × 21·4 mm; incubation by female, period 13–14 days; some males desert nest after hatching, otherwise chicks fed by both sexes, nestling period 12–14 days. Rarely parasitized by *Molothrus ater* (no cases in 401 nests from Illinois, in N USA), in part because of present species' earlier breeding season, possibly also because it ejects parasite's eggs; in recent study, rejection behaviour recorded at c. 33% of experimentally parasitized nests.
Movements. Mostly resident in S of range (Gulf Coast states, Georgia and Florida). Elsewhere a medium-distance migrant or partial or short-distance migrant, present in winter as far N as S Ontario (Canada) and Maine (USA). N populations (race *versicolor*) migratory, leaving breeding grounds Aug–Sept; peak S movement in Oct–Nov, and generally complete by Dec. Return migration from late Feb, and all N breeding grounds reoccupied by mid-Apr; males reach nesting areas at least one week before females.
Status and Conservation. Not globally threatened. Common to very common throughout range. Global population in 1990 estimated at c. 90,000,000 individuals. Regarded as an agricultural pest in many areas, where it causes damage by taking much cereal grain; subject to control measures in some regions.
Bibliography. 64. Nicaraguan Grackle

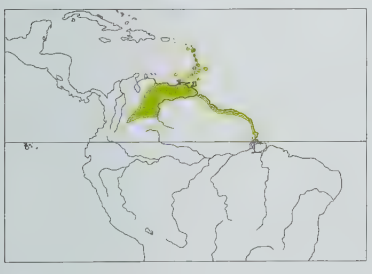
Quiscalus nicaraguensis

French: Quiscale du Nicaragua **German**: Nicaraguagrackel **Spanish**: Zanate Nicaragüense

Taxonomy. *Quiscalus nicaraguensis* Salvin and Godman, 1891, Momotombo, Lake Managua, Nicaragua.
Analysis of mitochondrial DNA indicates closer relationship with *Q. lugubris* than with other members of genus. Monotypic.
Distribution. S Nicaragua (shores of L Managua and L Nicaragua) and adjacent N Costa Rica (L Caño Negro, on R Frío).
Descriptive notes. Male 29 cm, 94 g; female 24 cm, 58 g. Male is black with marked violet and green gloss, gloss more violaceous on underparts, tail-coverts and tail; tail long and strongly keeled; iris pale yellow; bill long and thin, black; legs black. Distinguished from sympatric *Q. mexicanus* mainly by obviously smaller size. Female is smaller than male, upperparts dull brown, darkest on wings and tail; side of head dull brown contrasting with long pale, dull buffy superciliary and with pale underparts; submoustachial area, chin and throat very pale, dull buffy, becoming buff on breast and most of belly, deeper and richer on breast, paler on belly, dark brown on thigh, rearmost flanks, vent and undertail-coverts. Juvenile is grey-brown, paler below, with darker mottling; immature male is similar to adult, but duller and more brownish, with little gloss. Voice. Song by male during display a series of accelerated ascending whistles, also a descending "kleeep" during "Song Spread"



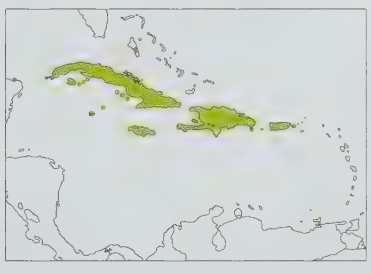
display; less varied and higher-pitched than song of *Q. mexicanus*. Calls include nasal "jep" and dry "jik"; also an ascending "wah-ee", like a call of *Q. mexicanus*.
Habitat. Open lakeshores, riverbanks, marshes and wet cattle pastures.
Food and Feeding. Feeds on wild seeds, also insects and other arthropods; probably also small vertebrates. Forages mostly on ground. Follows grazing cattle, and turns over small stones, debris and cow dung to find hidden prey; picks prey items from water surface. Commonly forages in small flocks, often with other icterids such as *Molothrus aeneus* and *Agelaius phoeniceus*; occupies peripheral positions when in mixed-species foraging flocks with *Q. mexicanus*.
Breeding. Season Mar–Sept (Costa Rica). Monogamous or polygynous. Breeds in small colonies, with up to ten nests together in trees and shrubs near water. In "Song Spread" display, male lowers head, erects body feathers, and spreads wings and tail while singing. Nest built by female, a coarsely constructed cup-shaped structure made from strips of marsh plants e.g. sedges and grasses, also with rootlets. Clutch 2–3 eggs, pale blue with dark to black spots and scrawls, mostly at large end, mean dimensions 26·5 × 18·7 mm; incubation by female alone, chicks fed by both sexes; no information on duration of incubation and nestling periods.
Movements. Apparently resident. Possibly some short seasonal movements.
Status and Conservation. Not globally threatened. Restricted-range species: present in Lake Nicaragua Marshes Secondary Area. Uncommon to locally common. Relatively poorly known. Estimated extent of distribution c. 7000 km²; fieldwork required in order more accurately to determine status. Adapts to moderate habitat disturbance.
Bibliography. Hellmayr (1937), Jaramillo & Burke (1999), Powell *et al.* (2008), Schönwetter & Meise (1982), Stiles & Skutch (1989).

65. Carib Grackle

Quiscalus lugubris

French: Quiscale merle **German**: Trauergrackel **Spanish**: Zanate Caribeño
Other common names: Lesser Antillean Grackle; Barbados Grackle ("*fortirostris* group")

Taxonomy. *Quiscalus lugubris* Swainson, 1838, Guyana.
Formerly placed with *Q. niger* in a separate genus, *Holoquiscalus*; thought to be closest to that species, but recent analysis of mitochondrial DNA indicates closer relationship with *Q. nicaraguensis* than with other members of genus. Races form two groups, "*fortirostris* group" (including *contrusus*), with blackish-brown females, and "*lugubris* group" (remaining six races), with paler brownish females; sometimes thought to represent two separate species, but darkness of females evidently variable. Further, a molecular-genetic (mtDNA) comparison of some mainland races with some island ones showed sequence divergence of 3·9%, indicating prolonged isolation, but many island races were not examined; mtDNA from two individuals from Barbados resembled that of distant Trinidad individuals, perhaps reflecting human introduction. More information on all races required. Proposed race *dispar* (described from Kingstown, on St Vincent) refers to occasional vagrants of *fortirostris*. Eight subspecies recognized.
Subspecies and Distribution.
Q. l. guadeloupensis Lawrence, 1879 – NC Lesser Antilles (Montserrat, Guadeloupe, Marie Galante, Dominica and Martinique).
Q. l. inflexirostris Swainson, 1838 – St Lucia, in C Lesser Antilles.
Q. l. contrusus (J. L. Peters, 1925) – St Vincent, in S Lesser Antilles.
Q. l. fortirostris Lawrence, 1868 – Barbados, in S Lesser Antilles.
Q. l. luminosus Lawrence, 1878 – the Grenadines and Grenada (S Lesser Antilles) and Los Testigos (off NE Venezuela).
Q. l. orquillensis (Cory, 1909) – Los Hermanos, off N Venezuela.
Q. l. insularis Richmond, 1896 – Margarita I and Los Frailes, off NE Venezuela.
Q. l. lugubris Swainson, 1838 – mainland Venezuela (S to middle and lower R Orinoco), NE Colombia (Orinoco basin in Arauca and Vichada), Trinidad and Tobago (possibly introduced), and E along coasts of Guyana, Suriname and French Guiana to N Brazil (Amapá).
Introduced (race *fortirostris*) in N Lesser Antilles (N of Montserrat); nominate race said to have been introduced on Tobago from Trinidad.



Descriptive notes. Male average 26 cm, 66–80 g; female average 21·7 cm, 49–58 g. Male nominate race is entirely black with strong violet gloss, slightly less glossy on underparts; gloss on wing-coverts more violet-blue, that on flight-feathers greener; tail medium-long and keel-shaped; iris pale yellow; bill and legs black. Female is dull dark brownish above, darker on wings and tail, somewhat paler below, throat paler and greyer; tail shorter than that of male, and with "normal" shape. Juvenile male is dark brown, sometimes faintly streaked below, with dark eyes, soon acquires black feathering in plumage and paler iris; juvenile female is similar to adult, but warmer brown, retains dark iris for longer than male. Races differ mainly in darkness of female (but individually variable), also in body and bill sizes, and nature of gloss on male: *guadeloupensis* has relatively short and thick bill, male gloss dull violet, greener on wing, female palest race, pale brown above, with pale buff lores and conspicuous buffy supercilium, light buffish below, with whitish chin and throat, streaked breast; *inflexirostris* is slightly larger than previous, bill marginally larger, female brown above with darker rump, indistinct lighter supercilium, wing and tail blackish with paler fringes, buff-brown below, slightly paler on throat and greyer on flanks; *contrusus* male is similar to last, female darkest race, blackish-brown above and below; *fortirostris* is smallest race, bill short and thick with gradually decurving culmen, female very dark, almost as dark as previous; *luminosus* has bill longer and more slender than others, male like *guadeloupensis* but violet gloss on head and body more extensive, female similar to preceding race but slightly paler, with paler throat and browner underparts, juvenile more obviously streaked below than those of other races; *insularis* is similar to nominate, but slightly smaller, both sexes have wing and tail longer, male less glossy; *orquillensis* male is like last, but central rectrices unglossed, rest of tail glossed green, female appears intermediate between the preceding two races in colour of underparts. Voice. Noisy. Male song varies considerably geographically, but generally a series of squeaky notes. In Martinique a descending, *Molothrus*-like whistle followed by a complex warble; in Trinidad a series of rhythmic rattles ending in metallic sound; in coastal Venezuela a frequent song is a series of 4–6 roughly similar ascending notes, "whep-whep-whep-whep-whep". Group singing frequent. Captive individuals reported as mimicking other bird species. Calls include "chk", loud whistles, and rattles.
Habitat. Open woodland and scrub, pastures, plantations, palm groves, parks and gardens, urban and suburban areas. Regularly found in large cities, such as Caracas (Venezuela).
Food and Feeding. Opportunistic and omnivorous, feeding on arthropods, small vertebrates, seeds and fruits. Vertebrates taken include *Anolis* lizards and eggs and chicks of small birds. In towns feeds on household food scraps (even entering restaurants), and garbage. Forages mostly in flocks or groups on ground. Associates with other icterids, such as *Molothrus bonariensis*.
Breeding. Breeds almost throughout year, mostly May–Sept in Trinidad and Jun–Jul in Venezuelan *llanos*. Monogamous, possibly sometimes polygynous. Nests solitarily or in small noisy colonies; up to 4–5 nests per palm in colonies in moriche palms (*Mauritia flexuosa*), and sometimes a dozen in single tree. Both sexes perform sexual and agonistic display involving the raising and spreading of tail and shaking of open wings. Nest built by female, a deep and bulky cup of grass and other plant material mixed with mud, lined with fine grass or similar fibres, external diameter 17 cm, external depth 10 cm, placed up to c. 15 m above ground in tree, palm or shrub, or in vine tangle; some colonies located over water in marsh or along channel, nests placed up to 2 m above water. Clutch 2–4 eggs, greenish-blue, spotted and scrawled with blackish-brown and grey, mean dimensions 27·3 × 19·8 mm (Trinidad); incubation by female, period 12 days; chicks fed by both parents, nestling period 14 days. Nests regularly parasitized by *Molothrus bonariensis* in *llanos* of Venezuela, where six of 13 nests in one colony had parasite eggs (a second colony with seven nests was not parasitized); none of 41 nests examined in Trinidad held *Molothrus* eggs (experiments in Trinidad showed that female ejected most parasitic eggs).
Movements. Resident. In highly seasonal environments such as Venezuelan *llanos*, some local movements probable. Race *fortirostris* apparently an occasional vagrant on St Vincent, but not reported there in recent decades.
Status and Conservation. Not globally threatened. Common to very common throughout range; locally abundant. Thrives in many modified environments. Race *fortirostris* was successfully introduced in early decades of 20th century in N Lesser Antilles, initially on Barbuda and Antigua, and evidently also St Kitts (then known as St Christopher); since then, has spread to other islands N to Anguilla. Nominate race said to have been introduced on Tobago (from Trinidad) in 1905, and now common on that island.
Bibliography. Belcher & Smooker (1937), Cherrie (1916), Friedmann & Kiff (1985), Friedmann & Smith (1955), Hilty (2003), Jaramillo & Burke (1999), Lefebvre *et al.* (1997), Lovette, Seutin *et al.* (1999), Manolis (1982), Morand-Ferron, Lefebvre *et al.* (2004), Morand-Ferron, Veillette & Lefebvre (2006), Powell *et al.* (2008), Raffaele *et al.* (1998), Ramo & Busto (1981), Selander (1971), Sick (1993), Wiley (1975).

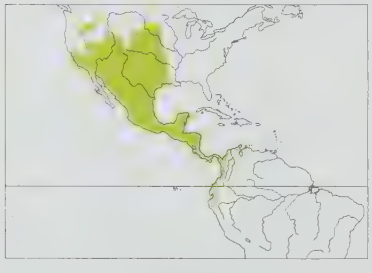
66. Greater Antillean Grackle

Quiscalus niger

French: Quiscale noir **German**: Antillengrackel **Spanish**: Zanate Antillano
Other common names: Antillean Grackle

Taxonomy. *Oriolus niger* Boddaert, 1783, Port-au-Prince, Haiti.
Formerly placed with *Q. lugubris* in a separate genus, *Holoquiscalus*; thought to be closest to that species, but recent analysis of mitochondrial DNA indicates that *Q. lugubris* is closer to *Q. nicaraguensis*. The same DNA study revealed moderate sequence divergences among four populations of present species (Grand Cayman, Jamaica, Hispaniola and Puerto Rico). Existence of two races in Cuba possibly due to fact that *gundlachii* evolved later and is slowly replacing *caribaeus* on main island; the two intergrade in W Cuba (Pinar del Río). Seven subspecies recognized.
Subspecies and Distribution.
Q. n. caribaeus (Todd, 1916) – extreme W Cuba (Pinar del Río), and I of Pines and adjacent cayos.
Q. n. gundlachii Cassin, 1867 – Cuba (E from Pinar del Río), including N cayos and Jardines de la Reina Archipelago.
Q. n. caymanensis Cory, 1886 – Grand Cayman I.
Q. n. bangsi (J. L. Peters, 1921) – Little Cayman I.
Q. n. crassirostris Swainson, 1838 – Jamaica.
Q. n. niger (Boddaert, 1783) – Hispaniola.
Q. n. brachypterus Cassin, 1867 – Puerto Rico and I de Vieques.

Descriptive notes. 25–30 cm; male 86·6–100 g and female 60–72·5 g (Cuba), male 67·5–88 g and female 51–64 g (*caymanensis*), male mean 112 g and female 79·3 g (*crassirostris*), male mean 86·4 g and female 61·7 g (*brachypterus*). Male nominate race is entirely black, with strong purple gloss on head and upperparts, including upperwing-coverts, and greenish gloss on flight-feathers and tail; tail long and graduated, wedge-shaped; iris yellow; bill and legs black. Female resembles male, but smaller, less glossy, and with smaller tail not held in wedge-shape. Juvenile is brownish-black, without iridescence, and has dark brown eyes. Races differ mainly in size and colour, nominate smallest and with most extensive purplish gloss: *gundlachii* of both sexes has violaceous plumage gloss; *caribaeus* is smaller than previous, with gloss bluish; *caymanensis* resembles last, but is much smaller, with blue gloss tinged purplish, uppertail-coverts glossed greenish-blue, upperwing glossed bronze-green; *crassirostris* is similar to *gundlachii*, but with shorter and thicker bill, male with violet sheen, this becoming blue on tail-coverts (above and below) and belly, with upperwing-coverts glossed greenish-bronze, female somewhat duller; *bangsi* is smaller than previous, with longer bill, male bluer, female more brownish; *brachypterus* resembles *crassirostris*, but smaller, with uppertail-coverts glossed purplish (not blue). Voice. Song varies considerably among islands, but (for a grackle) is relatively musical, a metallic "cling-cling-cling" and flute-like whistles. Call "chuk" or "chuk-chuk", or "chin-chin-chilin"; also high "wee-si-si" and harsh notes.
Habitat. Mangroves, marshes, savanna, coconut (*Cocos nucifera*) plantations, open fields, agricultural land, light woodland, parks and gardens; often roosts in towns and cities. Nominate race mostly below 1000 m, sometimes up to 2200 m; *crassirostris* mostly in lowlands.



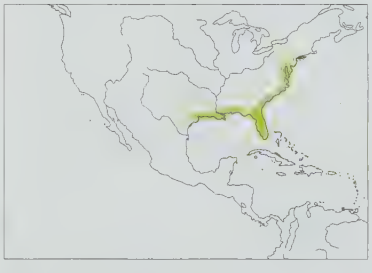
Food and Feeding. Omnivorous. Feeds on wild and cultivated seeds, including those of maize (*Zea mays*) and rice; takes insects and other arthropods; frequently preys on vertebrates such as *Anolis* lizards, even medium-sized Jamaican anole (*Anolis grahami*), and on eggs and chicks of small birds, including Banaquit (*Coereba flaveola*), grassquits (*Tiaris*) and Common Ground-dove (*Columbina passerina*); also eats fruits of *Bursera simaruba*. Often probes into ground and grass roots in search of arthropod prey. Commonly in flocks; sometimes several thousands at communal roosts.
Breeding. Season Feb–Sept, mainly Apr–Jul/Aug; Mar–Jul in Cuba. Mating system not well known. Colonial breeder, in trees; colonies in mangroves largest, up to c. 30 nests. Nest cup-shaped, made from plant materials including grass and Spanish moss (*Tillandsia*), reinforced with mud and lined with fine fibres, at variable height (in Cuba 5–16 m) above ground in tree, usually mangrove or palms (*Rostoynea*, *Cocos*, etc.); reported also as nesting in *Callophylum antillanum*. Clutch 3–4 eggs, pale olivaceous with brown to black spots and scrawls, mean dimensions 27·1 × 19·6 mm; no information on incubation period; male reported as feeding chicks, nestling period at least 23 days. Reported as host of *Molothrus bonariensis* in Puerto Rico, but experiments there showed that females eject most parasite eggs from nests.
Movements. Resident. Local movements to areas with fruiting trees reported from Jamaica.
Status and Conservation. Not globally threatened. Common to abundant throughout range, especially in lowlands. Often lives in towns and other modified habitats. Populations in smaller Cayman Is have suffered from hurricanes. Race *bangsi* formerly occurred also on Cayman Brac, but disappeared from there at some time between 1911 and 1970. Attempted introduced in Virgin Is (St Croix) c. 1917 was unsuccessful, and species soon died out there.
Bibliography. Balát & González (1982), Bradley (1995), Buden & Olson (1989), García Montaña (1998), Garrido (1973), Garrido & Kirkconnell (2000), Graves (2006), Jaramillo & Burke (1999), Keith *et al.* (2003), Lack (1976), Pérez-Rivera (1986, 2000), Post *et al.* (1990), Powell *et al.* (2008), Raffaele *et al.* (1998), Selander (1971), Wetmore & Swales (1931), Wiley (1985).

67. **Great-tailed Grackle**

Quiscalus mexicanus

French: Quiscale à longue queue **German**: Dohlengrackel **Spanish**: Zanate Mexicano

Taxonomy. *C.[orvus] mexicanus* J. F. Gmelin, 1788, area around Veracruz city, Veracruz, Mexico.
Closely related to, and may form a superspecies with, *Q. major*; occasional hybrids between the two reported along coast of S USA (in Texas and Louisiana). Related also to extinct *Q. palustris* of C Mexican plateau. Recent study of mitochondrial DNA revealed two clades with deep sequence divergence (3·1%), one formed by W races *nelsoni* and *graysoni*, the other including remaining races; despite DNA divergence, *nelsoni* hybridizes freely with *monsoni* in S USA (California and Arizona) following range expansions in 20th century. In Mexico, nominate race intergrades with *obscurus* in Guerrero (Balsas valley), with *prosopidicola* in S Tamaulipas, and with *loweryi* in extreme W Campeche. Eight subspecies recognized.
Subspecies and Distribution.
Q. m. nelsoni (Ridgway, 1901) – SW USA (from C California, Nevada and SW Arizona) S to NW Mexico (N Baja California and Sonora).
Q. m. monsoni (A. R. Phillips, 1950) – SW USA (SE California, C Arizona, Utah and Colorado S to New Mexico and W Texas) S to C Mexico (Zacatecas).
Q. m. prosopidicola (Lowery, 1938) – C & S USA (from Nebraska S to C Texas and Louisiana) and NE Mexico (Coahuila, Nuevo León and Tamaulipas).
Q. m. graysoni P. L. Sclater, 1884 – coast of Sinaloa, in W Mexico.
Q. m. obscurus Nelson, 1900 – W coast of Mexico from Nayarit S to Guerrero.
Q. m. mexicanus (J. F. Gmelin, 1788) – C Mexico (from E Jalisco, San Luis Potosí and S Tamaulipas) S to Nicaragua.
Q. m. loweryi (Dickerman & A. R. Phillips, 1966) – Yucatán Peninsula, including Cozumel I and other nearby islands, S to Belize.
Q. m. peruvianus Swainson, 1838 – Costa Rica, Panama, and Colombia E on Caribbean coast to NW Venezuela (Zulia) and S along Pacific coast to W Ecuador and extreme NW Peru (Tumbes).
Species is currently spreading N (& E) within USA, having now reached as far N as Oregon, South Dakota and Minnesota; this involves the three N races (*nelsoni* and *monsoni* in W, *prosopidicola* in E), but detailed information lacking as to exact range limits of each race, and situation complicated by extensive intergradation.



Descriptive notes. Male 43 cm, average 230 g; female 33 cm, average 125 g. Large icterid with large bill and long tail. Male nominate race is entirely black, with violet iridescence on head, back, throat and breast; more bluish gloss on rest of body, and greenish gloss on flight-feathers; tail long and graduated, keel-shaped, with greenish gloss; iris yellowish-white to pale yellow; bill and legs black. Female is much smaller than male, with shorter tail, plumage dark brown above, somewhat paler on head, with lighter supercilium, paler below, throat and breast lighter and warmer brown, contrasting with darker belly. Juvenile is similar to female, dark brown above and buffish-brown with dark streaks below, eyes dark. Races differ mainly in coloration (particularly of females), size and proportions, nominate largest and with relatively longest and deepest bill: *nelsoni* female is much paler than others, particularly on underparts (except belly) and supercilium; *graysoni* resembles previous in having pale females, both sexes slightly larger, and male has bluish (not violet) iridescence on back, breast and flanks; *monsoni* is similar to nominate, but somewhat smaller and not so heavy-billed, male with more prominent purplish gloss on back, female with slightly darker breast; *prosopidicola* is slightly smaller than nominate, female with paler head and paler buffy underparts; *obscurus* is smaller than nominate, female entirely dark brown, throat very slightly lighter, no visible supercilium; *loweryi* is like nominate, but distinctly smaller, female paler and warmer brown; *peruvianus* female is much paler than nominate, with clearly contrasting pale supercilium, light buff throat and underparts. Voice. Song of male variable within a colony, also among races. First part of song consists of hard notes, sound resembling cracking of twigs, this followed by "chewechewe" notes and a shorter sequence of twig-cracking notes, ending with loud "chawee" notes; song varies in pitch. Female produces a chatter, probably equivalent to male song. Calls include rising whistles (diagnostic call), rattles and guttural sounds; some male calls bugle-like, somewhat musical.
Habitat. Most types of habitat, except for unbroken forest. Found originally in marshes, coastal mudflats and lagoons, mangroves, and riparian habitat. Nowadays also in savannas, open fields, agricultural land, light woodland, and parks and gardens in towns and cities.
Food and Feeding. Omnivorous and opportunistic. Feeds on invertebrates, small vertebrates, carrion, berries and fruits, seeds, and discarded food scraps. Vertebrates taken include fish, frogs, lizards, small birds and mammals; preys on eggs and chicks of other birds, even of larger species such as herons (Ardeidae). Fruits consumed include cultivated bananas, those of Cuban royal palm (*Roystonea*) and wild berries of *Conostegia*. Forages on ground, sometimes with grazing livestock; also in bushes. Extracts insect larvae from soil, and turns stones to find hidden prey. May catch alates of termites (Isoptera) in air. Catches small fish and tadpoles by wading into shallow water, also while flying close to surface. Forages in small to large flocks.
Breeding. Season Mar–Jul in S USA (Texas) and Jan–Jul in Costa Rica; double-brooded in Guatemala and perhaps elsewhere in tropics. Colonial breeder, in compact colonies of up to c. 1000 nests, sometimes even more; often several nests in single tree, and inter-nest distance as small as 0·75 m. Polygynous, male defending small territory within colony in which one to several females nest; younger, short-tailed males aggressively excluded from colony; females in Texas engaged in frequent extra-pair copulations, which produced 37% of chicks. During sexual displays lowers head feathers, giving more slender look. Nest built by female, a bulky cup-shaped structure, outside diameter 18–20 cm, made from weed stems, coarse grass, sedges, vines or twigs, in towns may include scraps of paper or plastic, string, etc., material usually cemented with mud or cow dung, lining of fine fibres added, female often steals material from neighbouring nests; placed at good height in tree, sometimes suspended from branches with interlacing plant material, commonly in marsh vegetation over or near water, aquatic or riparian trees and shrubs selected including willows (*Salix*), buttonbush (*Cephalanthus*) and others, also in trees in farms and towns, and in Central America often in cultivated palm. Clutch usually 3 eggs in Guatemala and Costa Rica, 4 in S USA (Texas and Louisiana), means 3·5–3·7, bluish to bright blue with variable spots, blotches and scrawls in brown to black, mean dimensions 32·18 × 21·75 mm (Texas) and 33·6 × 23 mm (Guatemala); incubation by female, period 13–14 days; chicks fed by female, nestling period 20–23 days; male defends nests and chicks within its territory. Nests seldom parasitized by *Molothrus ater* and *Molothrus aeneus*, female almost invariably removing parasite eggs in experiments; has been suggested as being former host of *Molothrus oryzivorus* in areas S from Mexico until it evolved egg-ejection behaviour. In Louisiana, 36% of 183 eggs laid in 92 nests produced fledglings.
Movements. Apparently resident in most of range. A short-distance migrant in extreme N, though even these populations may not move during mild winters. Wintering ranges of the various races poorly known; race *prosopidicola* migrates along river valleys in Texas. Within USA, most birds resident nowadays, taking advantage of many sources of food associated with human settlements.
Status and Conservation. Not globally threatened. Common throughout range; abundant in man-made habitats. Has extended N since middle of 20th century, e.g. in Mexico colonized NW Sonora in 1940s–1950s and Baja California in 1960s; in USA has spread N & E since c. 1980, and has bred in Oregon and probably also in South Dakota; probably reached Louisiana in 1940s. Expansion in USA (at least) apparently continuing.

68. **Boat-tailed Grackle**

Quiscalus major

French: Quiscale des marais **German**: Bootschwanzgrackel **Spanish**: Zanate Marismeño

Taxonomy. *Quiscalus major* Vieillot, 1819, New Orleans, Louisiana, USA.
Closely related to, and may form a superspecies with, *Q. mexicanus*; occasional hybrids between the two reported along coast of S USA (in Texas and Louisiana). Four subspecies recognized.
Subspecies and Distribution.
Q. m. torreyi (Harper, 1934) – E USA from Long I (New York) S along coast to N Florida.
Q. m. westoni Sprunt, 1934 – most of peninsular Florida.
Q. m. major Vieillot, 1819 – SE Texas E along coast to extreme SW Mississippi.
Q. m. alabamensis Stevenson, 1978 – S Mississippi E along coast to NW Florida.

Descriptive notes. Male average 39·9 cm, 154–239 g; female average 27·5 cm, 93–147 g (*torreyi*). Male nominate race is entirely black, with violet gloss on head, blue-green gloss on body, and duller green gloss on wing and tail; tail long and graduated, wedge-shaped; iris brown; bill and legs black. Differs from similar *Q. mexicanus* in slightly smaller size, more slender bill, shorter and narrower tail, steeper forehead. Female is much smaller than male, dark brown above, with slight greenish gloss on wing and tail, ill-defined paler supercilium, cheek and often lores dusky, paler brown or buffy below, throat palest; bare parts as for male. Juvenile resembles female, but somewhat warmer brown, tinged cinnamon, above and below, no gloss, upperwing-coverts sometimes fringed rufous, breast sometimes indistinctly streaked. Races differ in size and iris colour: *torreyi* has longer wing than others, and pale yellow iris; *westoni* has longer and more slender bill, and yellow iris; *alabamensis* has thicker bill, yellow iris. Voice. Song, by both sexes (female more rarely) during display, a series of sharp "kip" notes followed by grating rattles, and ending with further "kip" notes. A common call is a harsh "jeeb-jeeb-jeeb"; also various whistles and harsher rattles.
Habitat. Brackish to freshwater marshes along coast, and bordering estuaries of main rivers. Nowadays also in man-made habitats, including cities (e.g. New Orleans) along coastal plain; also in inland marshes in Florida, rarely in inland locations elsewhere (such as Baton Rouge, in Louisiana).
Food and Feeding. Opportunistic and omnivorous. Feeds on small vertebrates, invertebrates, wild and cultivated seeds, tubers (e.g. potatoes), carrion, household scraps, even garbage. Vertebrates captured include fish, tadpoles, lizards, small birds, and small mammals; birds attacked or killed include Dunlin (*Calidris alpina*) and a perched swallow (Hirundinidae), and preys on eggs and chicks of many bird species; readily feeds on carrion, and said to pick pieces of flesh from trapped muskrats (*Ondatra zibethicus*). Invertebrates taken include molluscs (particularly mussels and freshwater *Pomacea* snails), crabs, shrimps and crayfish (Decapoda), spiders (Araneae), and insects (particularly of orders Orthoptera and Odonata). Wades into shallow water to pick crayfish, tad-

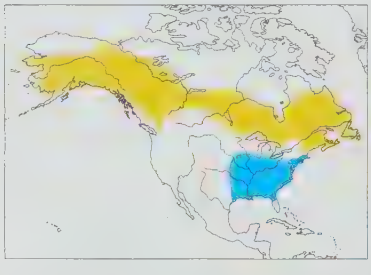
poles and fish; captures molluscs (snails, mussels) on shore or on floating vegetation. Often moistens bread, rice and dog food before eating it. Recorded as a kleptoparasite on Glossy Ibises (*Plegadis falcinellus*) feeding on crayfish. Forages in medium-sized to large flocks; in non-breeding season, usually in single-sex flocks.

Breeding. Season Mar–Jul, and egg-laying highly asynchronous; autumnal breeding (Nov) reported in Florida. Breeds in colonies of two to c. 200 nests, usually in zones free from most terrestrial predators; most colonies on small islands, and in man-made habitats sometimes in trees on traffic islands of main roads (where protected by automobile traffic); in area of range overlap with *Q. mexicanus* the two species may nest together, but with nests of present species in the minority and usually on the periphery. Mating system is harem polygyny, older dominant (or alpha) males defending a group of nesting females and performing more than 70% of copulations in colony, and siring more offspring than other males; males of lesser rank display outside colony; DNA fingerprinting revealed that 50% of females perform extra-pair copulations, particularly with males outside colony. During sexual displays, head feathers are raised or fluffed. Nest built by female, a bulky cup-shaped structure, outer walls usually of grass stems and leaves, cemented with mud and plant debris, lined with fine materials, including pine (*Pinus*) needles and thin grass stems, external diameter c. 19·7 cm, external depth the same; built 0·5–1 m above water in emergent aquatic plant or higher up in tree or shrub of various species. Clutch 1–5 eggs, mean 2·7, light blue, covered with brown and black scrawls, mean dimensions 31·9 × 21·8 mm; incubation by female, period 13 days; chicks fed by female alone, rarely assisted by male, nestling period 13 days; males in colony mob and attack potential nest predators.

Movements. Largely resident. Longer-winged N race *torreyi* a partial short-distance migrant, some moving S after breeding; one individual ringed as a chick in South Carolina was recovered 413 km S, in coastal E Florida, and others observed farther S in that state.

Status and Conservation. Not globally threatened. Common to locally abundant. Tolerates habitat modifications. Has expanded its range N & W.

Bibliography. Avise & Zink (1988), Bancroft (1984a, 1984b, 1985, 1987), Bent (1958), Bjorklund (1991), DaCosta *et al.* (2008), Dunham (1990), Hopkins *et al.* (2004), Jackson (1985), Jaramillo & Burke (1999), Kok (1972), Lowery (1974), McCarthy (2006), McIlhenny (1937), Melman & Searcy (1999), Post (1992, 1994a, 1994b, 1995, 1998a), Post & Seals (1993), Post *et al.* (1996), Poston (1997a, 1997b), Poston *et al.* (1999), Powell *et al.* (2008), Pratt (1991), Selander (1960), Selander & Giller (1961), Selander *et al.* (1969), Snyder & Snyder (1969), Sprunt (1931), Stevenson (1978).



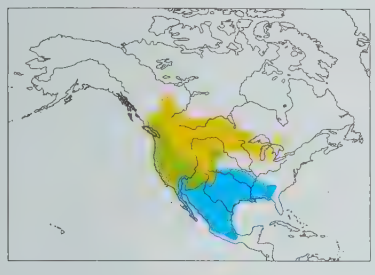
Genus *EUPHAGUS* Cassin, 1867

69. **Rusty Blackbird**

Euphagus carolinus

French: Quiscale rouilleux **German**: Roststärling **Spanish**: Zanate Canadiense

Taxonomy. *Turdus Carolinus* Statius Müller, 1776, Carolina, USA.
Closely related to *E. cyanocephalus*. Two subspecies recognized.
Subspecies and Distribution.
E. c. carolinus (Statius Müller, 1776) – breeds S of tundra from NW Alaska (Kotzebue Sound) E across Canada from Northern Territories (Mackenzie Delta) to Labrador, and S to extreme NE USA (New York state E to C Maine); migrates to E USA.
E. c. nigrans Burleigh & J. L. Peters, 1948 – breeds SE Canada (Newfoundland, Nova Scotia and New Brunswick); migrates to E USA.



Descriptive notes. Male 23 cm, 45·9–80·4 g; female 21 cm, 47–76·5 g. Male nominate race breeding is uniformly black with rather slight greenish or bluish gloss; iris yellow; bill and legs black. Differs from very similar *E. cyanocephalus* in being rather less glossy, and in having less heavy-looking bill. Female is slate-grey, usually darker above and with bluish-green gloss (more uniform slate-grey in worn plumage, with gloss often limited to upperwing-coverts); bare parts as for male. Male non-breeding is black with broad paler feather fringes, rusty brown on crown, nape and auriculars, with marked buff-brown supercilium, buff-brown on underparts (looking black-barred), and with wing, rump and tail black, tertials edged rufous; non-breeding female is similar to male, but fringes more cinnamon, and rump and underpart barring slate-grey. Juvenile is dull greyish, back and throat washed brown, wing feathers narrowly edged light brown; eyes dark, soon becoming paler. Race *nigrans* is very like nominate, but male has bluish (not greenish) gloss, and female is darker grey. VOICE. Male song described as a quiet gurgling sound followed by a shrill "kushaléé" and ending in a trill at 4 kHz; also a series of 2–3 musical notes and then a longer harsh note. Female song, sometimes delivered from nest, said to be different from male's, but few details. Common call, including in flight, a low "chuk"; alarm call "chip".
Habitat. Breeds in clearings within conifer forest and conifer–deciduous forest, usually near water in marshes and lakes; often nests around North American beaver (*Castor canadensis*) ponds; also favours openings and stands of young trees in boreal forest. In non-breeding range found mostly near water in wooded swamps, e.g. with bald cypress (*Taxodium distichum*), in riparian vegetation along creeks, also in open fields near swamps and wetlands. Usually roosts in trees, rarely on low vegetation near ground.
Food and Feeding. Has a rather broad-based diet, feeding on insects and other invertebrates, small vertebrates, carrion, seeds and some fruit. In summer consumes many aquatic insects and larvae, often of beetles (Coleoptera), also grasshoppers (Orthoptera); chicks commonly fed with dragonflies (Odonata). Other invertebrates taken include snails (Gastropoda), spiders (Araneae) and crawfish (Astacoidea). Preys on small vertebrates such as frogs and salamanders (Caudata); also attacks small birds, and known to kill, among others, longspurs and New World sparrows (Emberizidae) and goldfinches (*Carduelis*), and even *Molothrus ater*, attacks occurring mostly during severe cold weather. Feeds on tree seeds, i.e. acorns (*Quercus*) and pine seeds (*Pinus*), grass seeds (*Setaria*, *Panicum*), and some fruits, including elderberries (*Sambucus*) and blackberries (*Rubus*). Sometimes eats maize (*Zea mays*) and oat (*Avena*) seeds. Forages mostly on ground, in winter quarters frequently in ploughed fields. Often wades in shallow water to catch prey. Usually occurs in small groups, but in non-breeding season can also be encountered in flocks of up to c. 1000 individuals. In winter sometimes roosts with grackles and other icterids, and also with Common Starlings (*Sturnus vulgaris*).
Breeding. Season Apr/May–Jul; single-brooded. Apparently monogamous. Nests solitarily, in E of range also in small loose colonies. Nest built by female, often escorted by male, a bulky and strong cup 14–20 cm in external diameter, outer walls of twigs, grass and *Usnea* lichen, cemented with humid rotten vegetation (which dries up), lined mostly with grass, placed 0·5–6 m above ground in stump, tree or shrub growing in or close to water, often concealed in dense vegetation; trees used include conifers, i.e. spruce (*Picea*) and larch (*Larix*), and broadleaf species, i.e. willow (*Salix*), birch (*Betula*) and alder (*Alnus*); sometimes in dense vegetation on ground; old nests often used by Solitary Sandpiper (*Tringa solitaria*). Clutch 3–5 eggs, pale grey to blue-green, variably marked in brown, mean dimensions 25·8 × 18·6 mm; incubation by female, often fed by male (usually not on nest), period 14 days; chicks fed by both parents, nestling period 14 days. Rarely parasitized by *Molothrus ater*.
Movements. Strongly migratory, with no overlap between breeding and non-breeding ranges. Post-breeding movement to winter quarters in E USA, from Nebraska E to Massachusetts and S to E Texas and C Florida. Diurnal migrant. Leaves breeding grounds in Aug–Sept, arriving in S of non-breeding range Oct–Nov; remains in winter quarters until Feb. Return migration from mid-Feb, reaching S edge of breeding range in Mar (mean spring arrival date in Nova Scotia c. 24th Mar); many do not arrive until May/Jun in N of range. During migration occurs irregularly in Colorado, mostly E of Rocky Mts, and even farther W, some reaching extreme NW Mexico (Baja California). Lost migrants have landed on ships up to 400 km off E coast of USA. Recorded as accidental in Russian Far East, islands in Bering Sea and Greenland.
Status and Conservation. VULNERABLE. Classified as "Declining" in the USA (Yellow WatchList priority species for conservation). Estimated total population 2,000,000 individuals in period 1980–1990, but since then has declined steeply to probably no more than a few hundred thousand. Destruction of habitat may be one of main causes of decline. Has suffered serious long-term population decline that appears to have accelerated since end of last century. Historical accounts indicate that numbers have been falling steadily for more than a century, and recent surveys have revealed annual rates of decline of c. 5% to 12% since 1970s. Possible reasons for this include loss and degradation of wooded wetlands, habitat on which this species is dependent throughout year; this has been a particular problem in non-breeding range. In recent decades, habitat disturbance and environmental pollution, as well as global climate warming, may have had adverse effects on breeding. In 2005, the International Rusty Blackbird Working Group was set up with aim of developing research that would shed light on causes of decline; some early findings were that methylmercury levels in tissues were higher in breeding area than in wintering range, and that, in winter, individuals are vulnerable to parasite and microbial infections (possibly a result of stress induced by degradation of wintering habitat). In addition, when the species nested in small stunted conifers in undisturbed wetlands in Alaska and New England, it achieved relatively high success; in contrast, when those in New England nested in young spruces or balsam firs (*Abies balsamea*) that had regrown after recent logging of wetlands or adjacent uplands, they suffered far greater nest predation, leading to huge reduction (almost 70%) in nest survival; researchers suggested that establishment of unlogged buffer zones around wetlands should be considered as a conservation measure for this icterid. Sometimes consumes maize (*Zea mays*) and oat (*Avena*) seeds, but causes only minor crop damage; nevertheless, it suffers some mortality from poisoning at winter roosts, where it mixes with other icterids (grackles, *Agelaius phoeniceus*, etc.) and Common Starlings that are subject to pest control.
Bibliography. Anon. (2010d), Avery (1995), Barnard *et al.* (2010), Bent (1958), Butcher & Rowher (1988), Edmonds *et al.* (2010), Gabrielson & Lincoln (1959), Godfrey (1986), Greenberg & Droege (1999), Greenberg & Matsuoka (2010), Hobson *et al.* (2010), Hoffman & Hoffman (1982), Jaramillo & Burke (1999), Kennard (1920), Kenyon & Phillips (1965), Lebbin *et al.* (2010), Lewis (1931), Luscier *et al.* (2010), Matsuoka, Shaw & Johnson (2010), Matsuoka, Shaw, Sinclair *et al.* (2010), McCaskie (1971), Meanley (1995), Mettke-Hofmann *et al.* (2010), Orians (1985a), Powell, Hodgman & Glanz (2010), Powell, Hodgman, Glanz, Osenton & Fisher (2010), Rich *et al.* (2004), Taylor (1987), Woodruff & Woodruff (1991).

70. **Brewer's Blackbird**

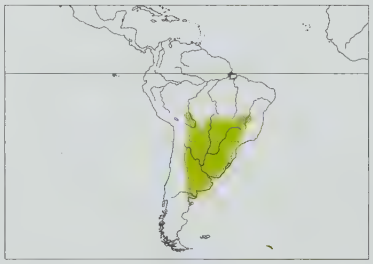
Euphagus cyanocephalus

French: Quiscale de Brewer **German**: Purpurstärling **Spanish**: Zanate de Brewer

Taxonomy. *P.*[*sarocolius*] *cyanocephalus* Wagler, 1829, Temascáltepec, Mexico.
Closely related to *E. carolinus*. Monotypic.
Distribution. Breeds in S Canada from N British Columbia E across Alberta and Saskatchewan to S Ontario, throughout W USA S to California and New Mexico and E to N Nebraska and Michigan, and in NW Mexico (including N Baja California). N breeders migrate to SW parts of breeding range and S to S USA and S Mexico.

Descriptive notes. Male 23 cm, 60–73 g; female 21 cm, 50·6–67 g. Male is glossy black, with purple iridescence on head and neck, greenish to bluish iridescence on rest of plumage; iris yellow; bill and legs black. Some non-breeding males (possibly yearlings) may have buff-edged feathers. Female is dark greyish-brown, with slightly paler supercilium, slightly paler below, darker on belly, has slight violaceous gloss on head, greenish gloss on back; iris dark brown, occasionally paler; bill and legs as on male. Juvenile is like female, but more uniformly coloured, browner and without gloss. Voice. Song, by both sexes, a brief but varied "skwéé" or a "schrlup". Common call "chuk"; scolding "tschup".
Habitat. Original inhabited clearings and edges of several forest types, ranging from chaparral to montane conifer woodland. Nowadays common in modified habitats, such as pastures, agricultural land, farms, towns and suburban areas. Lowlands and mountains; to 3000 m.
Food and Feeding. Diet consists of invertebrates, small vertebrates, seeds; more rarely, fruits. Stomach contents of 285 birds from California mostly insects and seeds; insects chiefly beetles (Coleoptera, of 13 families), flies (Diptera), bugs (Hemiptera), Orthoptera and Lepidoptera. Seeds taken from both cultivated plants (wheat, oats) and wild plants. Reported as killing and eating other birds, also as taking nestlings. During breeding, food for chicks obtained up to 800 m from colony. Forages on ground. Commonly forages in flocks, which in winter can contain a few thousand individuals.
Breeding. Season Apr–Jul; in resident populations (coastal California) courtship and pair-forming starts in Jan and takes 5–12 weeks, but elsewhere this period shorter; second broods frequent in W USA (coastal Oregon and California). Nests solitarily or in colonies of mostly 3–20 nests, rarely up to 100 nests; up to seven nests per tree in California colonies. Monogamous to moderately polygynous, number of polygynous males in California dependent on sex ratio at colonies, varying from year to year, and males had maximum of three mates; nests of polygynous males often not adjacent, but scattered within colony; territorial defence limited to small area around nest-site. Nest built by female, a bulky cup of diverse plant materials, reinforced with mud and cow dung, lined with horsehair and rootlets, external diameter c. 15 cm, external depth c. 7·5 cm, built on ground, or in shrub or marsh vegetation, or up to 50 m above ground in dense foliage of tree, rarely in hole in broken top of dead tree or old woodpecker (Picidae) hole; both native trees and shrubs, e.g. Monterey pine (*Pinus radiata*) and sagebrush (*Artemisia*), and exotic ones, e.g. eucalypts (*Eucalyptus*), used; female may change nest location between seasons. Clutch 3–7 eggs, pale blue or greenish-blue, variably marked with spots, blotches and lines in shades of brown, purplish-brown and black, mean dimensions 25·5 × 18·6 mm; incubation by female, sometimes fed by male, period 12–13 days; polygynous male deserts primary female during incubation; hatching asynchronous, chicks fed usually by both sexes, polygynous males divide their efforts, nestling period 13 days. Nests parasitized by *Molothrus ater*.
Movements. Resident along Pacific coastal region, from SW British Columbia (Canada) S to N Baja California (Mexico); individuals ringed in C coastal California observed no farther than c. 10 km from capture site. Elsewhere, a short-distance to medium-distance migrant, moving S after breeding to S parts of breeding range and to S half of USA (E to NW Florida) and Mexico (S to Michoacán, Oaxaca and Veracruz); recorded rarely as far S as Guatemala. In addition, altitudinal movements occur in W of range (in Rockies and Sierra Nevada).
Status and Conservation. Not globally threatened. Common to locally abundant. Since early decades of 20th century has expanded into E parts of North America, most of this spread 1920s–1940s, but continuing thereafter; formerly bred no farther E in USA than W Minnesota, but by early 1970s range had extended to S Ontario (Canada), with concomitant E expansion of non-breeding range in C & S USA. Quite tolerant of human modifications of habitats; prefers relatively open habitats. Range extension aided by forest clearance.

Bibliography. Balph (1975), Bent (1958), Butcher & Rowher (1988), Butler (1981), Furrer (1975), Grinnell (1920), Harms *et al.* (1991), Horn (1968, 1970), Howell, S.N.G. & Webb (1995), Howell, T.R. & Bartholomew (1952, 1954), Jaramillo & Burke (1999), Koenig (1985), La Rivers (1944), Martin (2002), McCarthy (2006), Orians & Horn (1969), Power (1971a, 1971b), Ritter (1983), Soriano (1931), Stepney (1975), Stepney & Power (1973), Verbeek (1964), Westmoreland & Kiltie (1996), Wiggins (1990), Williams (1952).



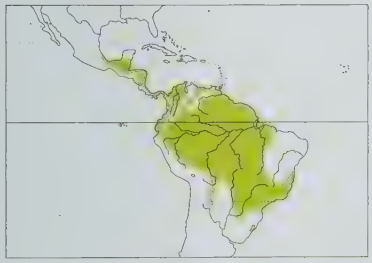
Genus *MOLOTHRUS* Swainson, 1832

71. Screaming Cowbird

Molothrus rufoaxillaris

French: Vacher criard **German**: Rotachsel-Kuhstärling **Spanish**: Tordo Chillón
Other common names: Short-billed Cowbird

Taxonomy. *Molothrus rufo-axillaris* Cassin, 1866, Buenos Aires, Argentina.
Analyses of mitochondrial DNA indicate closest relationship with *M. oryzivorus* and *M. aeneus*. Monotypic.
Distribution. SE Bolivia and C Brazil (S from Mato Grosso, S Tocantins, Goiás, and W Minas Gerais), S throughout Paraguay and Uruguay to NE & C Argentina (S to Río Negro and NE Chubut).
Descriptive notes. Male 20·3 cm, average 58 g; female 19·2 cm, average 48·8 g. Male is entirely black with bluish iridescence (ultraviolet reflectance slight), except for rufescent lesser underwing-coverts (rarely seen in the field); iris reddish-brown; bill and legs black. Differs from very similar male *M. bonariensis* in lacking strong purplish-blue and green gloss, and in having thicker bill. Female is very like male, but slightly smaller and duller, with smaller rufescent patch on underwing. Juvenile out of nest is very similar to host chick (*Agelaioides badius*), slowly acquires black adult plumage in patches, usually starting moult at c. 30 days; in last stage, black with chestnut flight-feathers. Voice. Rather noisy, commonly vocalizing throughout year. Song, by perched male, a brief, piercing and explosive "klúish!" (often preceded by low "grrr", audible only at close range); female may answer with loud rasping rattle, in a kind of duet. Male also produces rasping calls. Fledgling mimics calls of host's chick.
Habitat. Original habitat probably grassland near woodland edge, and open woodlands of many types, particularly *chaco* woodland with mesquite (*Prosopis*) and acacias (*Acacia*), also savannas, including palm savannas with *Butia yatay* and *Copernicia alba*. Nowadays common in pastures, agricultural land, farms, parks, towns and suburbs. Avoids dense unbroken woodland. Roosts in dense vegetation, rarely in marshes. Lowlands to 1800 m.



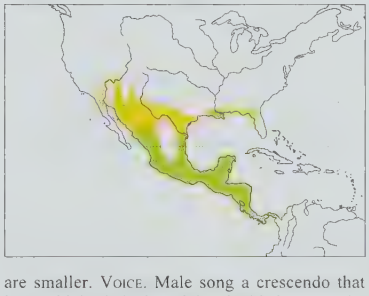
Food and Feeding. Insects and other arthropods, and seeds. Insects in stomach contents include beetles (of families Chrysomelidae and Scarabaeidae) and ants (Formicidae). Rarely, takes flower nectar from introduced trees, such as *Grevillea robusta*. Forages mostly on ground, commonly around grazing domestic mammals. May flock with *Agelaioides badius* and *Gnorimopsar chopi*, even when not breeding, or with *M. bonariensis* and *M. oryzivorus*. Roosts with hosts or with other icterids.
Breeding. Season Oct–Mar in C Argentina. Apparently monogamous; male accompanies female constantly, pair-bond lasts a minimum of one or two seasons. Male displays by puffing body feathers and bowing while singing. A brood parasite with three main hosts, all icterids with co-operative breeding habits, i.e. *Agelaioides badius*, *Gnorimopsar chopi* and, to lesser extent, *Pseudoleistes virescens*; recently found to parasitize also non-co-operative *Procacicus solitarius* and Cattle Tyrant (*Machetornis rixosa*) in NE Argentina, these cases believed possibly a result of recognition errors by female of present species. Pair visits host nests at least twice per hour, sometimes displaying around them; often punctures or pecks host eggs. May lay more than 1 egg per host nest, and sometimes a single nest parasitized by many females; up to 19 parasitic eggs recorded in one nest, but such large numbers abandoned by host; eggs harder-shelled and more rounded than host eggs, and bluish, greyish or pinkish, variously marked with spots, scrawls and blotches in shades of brown, mean dimensions 23·1 × 17·9 mm; incubation of single egg 12 days; nestling resembles that of *Agelaioides badius*, differing in small details (bill colour, feathering of head, etc.); nestling period usually 12–13 days. Successful chicks of present species, particularly males, are larger and heavier than those of *Agelaioides badius*, larger even than adults of latter; once fledged, may remain with host parents or helpers for up to 6 weeks; after independence may form temporary groups of their own, which eventually join adult population of own species. In one study, *Agelaioides badius* fledged on average one chick of present species for every three of its own chicks. Female may pair when still in immature (heavily worn) plumage.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Locally uncommon to common. Has more than doubled the extent of its range in the last 50 years, probably assisted by conversion of natural vegetation (*campos*, *cerrados* and Atlantic Forest) into agricultural fields. In Brazil, has spread N as far as Tocantins–Maranhão–Bahia border, following its principal host in Brazil, *Gnorimopsar chopi*; reported in Bolivia from Beni, Santa Cruz and Tarija, but range there not well known. Its known main hosts, so far, are rather abundant icterid species that are not seriously declining. Range expansion appears to be continuing.
Bibliography. D'Angelo Neto (2000), De Mársico & Reboreda (2008), Di Giacomo, A.G. *et al.* (2010), Fraga (1979, 1983b, 1996, 1998, 2006, 2008c), Friedmann (1929), Herrera & Vidoz (2009), Hoy & Ottow (1964), Hudson (1920), Jaramillo & Burke (1999), Kirwan (2009), Lichtenstein (2001), Llambías *et al.* (2006), Mason (1980, 1987), Mermoz & Fernández (2003), Mermoz & Reboreda (1996), Pacheco & Olmos (2006), Sick (1993), Zotta (1936).

72. Giant Cowbird

Molothrus oryzivorus

French: Vacher géant **German**: Riesenkuhstärling **Spanish**: Tordo Gigante
Other common names: Rice Grackle

Taxonomy. *O.*[*riolus*] *oryzivorus* J. F. Gmelin, 1788, Cayenne, French Guiana.
Formerly placed in genus *Psomocolax* or *Scaphidura*, but such treatment not supported by molecular-genetic findings. Analyses of mitochondrial DNA indicate closest relationship with *M. rufoaxillaris* and *M. aeneus*. Geographical variation weak; further study desirable. Race *impacifus* commonly emended to "*impacificus*" but, in absence of any internal evidence in original description (where same original spelling appears three times), there is no justification for such a change under the International Code of Zoological Nomenclature. Two subspecies tentatively recognized.
Subspecies and Distribution.
M. o. impacifus (J. L. Peters, 1929) – E Mexico (Veracruz) S to W Panama.
M. o. oryzivorus (J. F. Gmelin, 1788) – C Panama E to Colombia, S on Pacific coast to NW Peru (Tumbes), and from Venezuela, Trinidad and Tobago and the Guianas S to E Peru, Bolivia, N & NE Argentina (Jujuy, Salta and N Corrientes) and most of Brazil (S to Santa Catarina; absent in NE).



Descriptive notes. Male 34 cm, 174–242 g; female 29 cm, 144–167 g. A large, long-winged and long-tailed black interid, erectile feathers around neck forming ruff; in its undulating flight resembles a corvid, e.g. Purplish Jay (*Cyanocorax cyanomelas*), more than it does an icterid. Male nominate race is entirely black, with bronze to bluish iridescence; ultraviolet reflectance present in patches; inconspicuous black frontal casque covered by feathers; conspicuous neck ruff (making head appear small); iris variable, yellow to orange-yellow; bill and legs black. Female is smaller and duller than male, with smaller ruff. Fledged chick has blackish plumage, and pale yellow bill that eventually becomes black. Race *impacifus* differs from nominate only in having violaceous (not bluish to bronze) iridescence. Voice. Rather silent. Song usually a high-pitched, shrill whistle followed by a warble "psee-pseerere-pic-pic". Female produces harsh rattle. A "chuk" call given by both sexes. Audible wingbeats in flight.
Habitat. In breeding season often near colonies of *Psarocolius* and *Cacicus* at forest edge, in large clearings and savannas, and around pastures and lawns, even in small towns. During rest of year frequents open habitats along main rivers and channels, particularly exposed stony beaches and riverbeds; found also around livestock pastures. Lowlands up to c. 1500 m (nominate race); *impacifus* to 1700 m in Costa Rica.
Food and Feeding. Insects and other invertebrates, and seeds; sometimes takes nectar from brush-shaped inflorescences of *Combretum* vines. In NE Argentina (near Iguazú), early in morning, seen to peck, dismember and eat large insects attracted by artificial lights (building or street lights), including scarab beetles (Scarabaeidae) and giant water bugs (Belostomatidae) up to 7 cm long. Forages mostly on ground, often around domestic livestock (cattle, horses), also around some wild grazing mammals such as capybaras (*Hydrochoerus hydrochaeris*) and tapirs (*Tapirus*); catches tabanid flies around grazing mammals. In French Guiana one seen to pick insects from skin of brown-throated sloth (*Bradypus variegatus*). Often turns stones and cow dung, debris and garbage in search of concealed prey. Usually in small flocks, rarely of more than 20 individuals; may associate with other gregarious, ground-feeding icterids, including congeners and *Quiscalus*. Roosts in larger groups, reaching 2000 individuals on river islands of Amazonian Peru, often with other icterids.
Breeding. Season Apr–Nov in Panama, Dec–Apr in Suriname and Sept–Dec in NE Argentina. Brood parasite mostly on colonial species of cacique (*Cacicus haemorrhous* and *Cacicus cela*) and oropendolas (reported so far for *Psarocolius decumanus*, *Psarocolius wagleri*, *Psarocolius angustifrons*, *Psarocolius viridis* and *Psarocolius montezuma*; observed also to visit nesting colonies of *Psarocolius yuracares*); Green Jay (*Cyanocorax yncas*) confirmed as a host in a Venezuelan valley without oropendolas or caciques, also one chick in Colombia was fed by Green Jays and two chicks in Ecuador fed by Turquoise Jays (*Cyanolyca turcosa*), the last two possibly rare cases of fledgling adoption; also, fledglings fed by *Icterus pectoralis* and *Icterus pustulatus* in Nicaragua. Usually deposits 1 or 2 eggs per host nest, but some nests contain up to 6 parasite eggs (possibly laid by more than one female); eggshell particularly thick and rough, colour variable, plain white, pale blue with some brown or blackish spots and lines, or pale buffish-white with brownish spots and lines (this variation found in Panama, Venezuela, Trinidad, Suriname and Argentina, and probably elsewhere, and different egg types found in single host colony), mean dimensions 34·2 × 25·1 mm; some eggs resemble those of particular hosts, but so far no conclusive evidence for regular mimicry of host eggs; some hosts (*Psarocolius montezuma*) regularly remove cowbird eggs, also present species possibly removes or pecks host eggs; incubation period 12–13 days; nestling has pale bill and ivory-coloured casque, resembling some *Psarocolius* oropendolas (possibly a case of mimicry); nestling period relatively long, 16–20 days; post-fledging period of dependence on host mostly unknown. Host nests sometimes severely infested by ectoparasitic flies of genus *Philornis*, often leading to death of host chicks; in Panama, chicks of present species reported to remove the fly larvae from both host chicks and themselves, but elsewhere in range this seems not to occur.
Movements. Apparently resident. Probably some short-distance movements between breeding and non-breeding habitats. Nominate race recorded as an accidental visitor in Barbados (West Indies).
Status and Conservation. Not globally threatened. Uncommon to fairly common or locally common; widespread. Rare or absent from several states of NE Brazil; scarce and local in *llanos* of R Orinoco in Venezuela and in Trinidad and Tobago. Well adapted to human-modified and artificial environments, provided that sufficient supply of host nests exists; has possibly increased. Found in many protected areas throughout its large range, such as Manu National Park (Peru), Amboró National Park (Bolivia), Pantanal Mato-grossense National Park (Brazil) and Iguazú National Park (Argentina), among others.

73. Bronzed Cowbird

Molothrus aeneus

French: Vacher bronzé **German**: Rotaugen-Kuhstärling **Spanish**: Tordo Ojirrojo
Other common names: Red-eyed Cowbird

Taxonomy. *P.*[*sarocolius*] *aeneus* Wagler, 1829, Veracruz, Mexico.
Formerly placed in genus *Tangavius*, but such treatment not supported by molecular-genetic findings. Analyses of mitochondrial DNA indicate closest relationship with *M. rufoaxillaris* and *M. oryzivorus*. Often considered conspecific with *M. armenti*, but shows more marked sexual dichromatism and also differs vocally. Three subspecies recognized.
Subspecies and Distribution.
M. a. loyei Parkes & Blake, 1965 – breeds from SW USA (S California, Arizona, New Mexico and W Texas) S in W Mexico to Nayarit and N Baja California.
M. a. aeneus (Wagler, 1829) – breeds in S USA (S Texas, Louisiana and Florida) and from E & C Mexico S, including nearby islands (e.g. Cozumel I), to C Panama.
M. a. assimilis (Nelson, 1900) – SW Mexico from Jalisco S to Chiapas.

Descriptive notes. Male 20 cm, average 68·9 g; female 18 cm, average 56·9 g. Male nominate race is mostly black with bronze gloss, including erectile neck ruff, but iridescence on wing and tail mostly blue to blue-green, rump with violaceous iridescence; iris bright red; bill and legs black. Female is blackish overall, with minimum of iridescence, and lacks neck ruff. Juvenile resembles female, but paler and browner, with dark eyes and horn-coloured bill. Races differ mainly in female plumage and in size: *loyei* is larger than others, female paler, mostly greyish-brown, with vaguely streaked underparts; *assimilis* is very like previous, but both sexes are smaller. Voice. Male song a crescendo that includes short introductory notes followed by longer high-pitched modulated whistles, or a single descending whistle followed by rasping warble. Both sexes utter harsh "chuck" call; female has rattle.
Habitat. Open country in areas with xeric to humid vegetation, usually avoiding dense forest or woodland. Usually in grasslands, pastures, plantations, farms, roadsides, and even urban and suburban habitats. Lowlands to 3000 m.
Food and Feeding. Mostly seeds and arthropods. Stomach contents of fully adult males more than 90% seeds (including of cultivated *Sorghum vulgare*), the rest being insects, spiders (Araneae) and snails (Gastropoda). Reported as feeding on rice. In Texas forages in winter near grain-elevators, feeding on spilt seed. Forages mostly on ground; locates hidden prey by turning small stones. Often follows grazing livestock, and picks ticks (Ixodoidea) from their skin. Usually in flocks, sometimes of up to 600 individuals; may associate with *M. bonariensis*, *M. oryzivorus* and *Quiscalus mexicanus*.
Breeding. Season Apr–Jul. Apparently polygynous or promiscuous. Male displays expanded ruff while singing from perch; sings also during "Helicopter Display", hovering for up to 15 seconds 0·5–1 m above perched female, during which he fluffs his body feathers, resembling a ball. A generalist brood parasite, with c. 100 reported hosts, mostly passerines; frequent hosts include tyrant-fly-

On following pages: 74. Bronze-brown Cowbird (*Molothrus armenti*); 75. Brown-headed Cowbird (*Molothrus ater*); 76. Shiny Cowbird (*Molothrus bonariensis*).

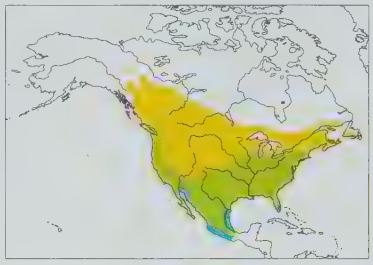
catchers (Tyrannidae), wrens (Troglodytidae), mockingbirds (Mimidae), vireos (Vireonidae), tanagers (Thraupidae), New World sparrows and buntings (Emberizidae), and other icterids (about ten species of *Icterus* are known hosts of present species); in parts of Arizona where sympatric with *M. ater*, little overlap between the two in host selection. Sometimes small groups visit a host nest, eggs laid mostly at dawn; often punctures or removes host eggs. Most host nests contain 1 cowbird egg, but multiple parasitism occurs; eggs bluish-white to bluish-green, unmarked, mean dimensions 23·6 × 18·3 mm (nominate race), 24·5 × 17·1 mm (*loyei*); incubation period for single eggs 10–12 days; hatchling has orange-pink skin, dusky-yellow bill and legs, white to cream rictal flanges and red mouth, nestling period 10–12 days; post-fledging period of dependence on host up to 14 days.
Movements. Populations in most of USA range (California, Arizona, New Mexico, Texas and Louisiana) and in CN Mexico (particularly Coahuila) short-distance migrants; no information available on distances travelled. Elsewhere in Mexico and in Central America apparently resident; altitudinal movements in highlands.
Status and Conservation. Not globally threatened. Common to fairly common in most of range, less common in interior Mexico; less numerous than *M. ater*. Somewhat more local in non-breeding season. Nominate race has extended its range in N following agricultural expansion, and populations in Louisiana and Florida are result of a recent expansion; in contrast, *loyei* has declined locally because of habitat loss. This cowbird is not subject to control measures in USA.
Bibliography. Carter (1986), Chace (2005), Clotfelter (1995), Clotfelter & Brush (1995), Dickerman (1960), Eisenmann (1957), Ellison *et al.* (2006), Friedmann (1929, 1963), Friedmann & Kiff (1985), Friedmann *et al.* (1977), González-García (2007), Howell & Webb (1995), Jaramillo & Burke (1999), Kostecke *et al.* (2004), Lowther (1995), Parkes & Blake (1965), Peer & Sealy (1999a, 1999b), Robbins & Easterla (1981), Rowley (1984), Sealy *et al.* (1997), Stiles & Skutch (1989), Thurber & Villeda (1980), Warren (2002, 2003), Wetmore *et al.* (1984).

74. Bronze-brown Cowbird

Molothrus armenti

French: Vacher brun **German**: Zwergkuhstärling **Spanish**: Tordo Chico
Other common names: Colombian/Arment's Cowbird

Taxonomy. *M.[olothrus] armenti* Cabanis, 1851, Cartagena, Colombia.
Often considered conspecific with *M. aeneus*, but shows reduced sexual dichromatism and also differs vocally. Monotypic.
Distribution. Caribbean coast of N Colombia (N Bolívar, Atlántico and Magdalena).



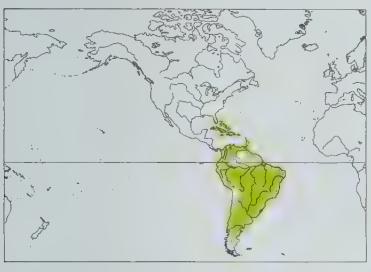
Descriptive notes. Male 18·6 cm, average 40·8 g; female 16 cm, average 30·7 g. A small cowbird with neck ruff. Male has head, back and underparts dark sepia with strong coppery iridescence, wing and tail blackish with blue to purple gloss; iris brick-red to red; bill and legs black. Differs from *M. aeneus* mainly in smaller size and in dark brown (rather than black) plumage coloration. Female is similar to male, but less glossy and duskier in colour, with smaller ruff. Juvenile is duller than female, uniformly brown to dusky brown, unglossed, head with slightly paler supercilium and dark eyestripe, no visible streaks or stripes below, iris coffee-brown, bill and legs dark horn-coloured. Voice. Male song during display an ascending, high-pitched "eez-eez-dzleeee", with rasping or glassy tone, reaching 9500 Hz. Also produces a high-pitched metallic whistle.
Habitat. Occupies dry woodland with *Prosopis juliflora*, *Acacia farnesiana* and arborescent cacti, also second-growth scrub, agropastoral land, roadsides; also mangroves. Arid tropical lowlands up to 50 m.
Food and Feeding. Little information. Diet probably mostly arthropods and seeds; frequents farms and barnyards, and feeds on chicken food. Forages mostly on ground, in small flocks of up to c. 30 individuals; may associate with *M. bonariensis* and *Quiscalus mexicanus*.
Breeding. Season May–Jul; fledged chicks seen in Jul. In "Song Spread" display, male lowers head, raises body feathers and spreads wings and tail while singing. Brood parasite; hosts remain unknown, presumably small passerines. No other information.
Movements. Apparently resident.
Status and Conservation. Not assessed. Classified as "endangered" in Colombia. Little known. Extremely local, and total population must be small. An old report from Leticia (Amazonian Colombia) is erroneous. Reasons for this species' restricted range not clear, as its dry woodland habitat extends well into Venezuela. Found in at least one protected area, Isla de Salamanca National Park.
Bibliography. Borja *et al.* (2001), Dugand & Eisenmann (1983), Friedmann (1933, 1957), Hilty & Brown (1986), Jaramillo & Burke (1999), López-Lanús (2005b), Núñez-Santamaría & Rodríguez-Berrocal (2002), Rada Quintero (2002).

75. Brown-headed Cowbird

Molothrus ater

French: Vacher à tête brune **German**: Braunkopf-Kuhstärling **Spanish**: Tordo Cabecipardo
Other common names: Common Cowbird

Taxonomy. *Oriolus ater* Boddaert, 1783, Carolina, USA.
Closely related to *M. bonariensis*, and much resembling it in habits, general behaviour and voice. Race *obscurus* intergrades with *artemisiae* in Sierra Nevada (California). Proposed race *californicus*, described from L Buena Vista (Kern County), in SC California, is subsumed in *obscurus*. Three subspecies recognized.
Subspecies and Distribution.
M. a. obscurus (J. F. Gmelin, 1789) – breeds along Pacific seaboard from S Alaska S (E to the Cascades and Sierra Nevada) to NW & N Mexico (N Baja California, also on mainland S to Oaxaca); N populations migrate to S parts of breeding range, in Mexico extending to S Baja California.
M. a. artemisiae Grinnell, 1909 – breeds from W Canada (interior British Columbia E to SC Manitoba) S in W USA (E from the Cascades and Sierra Nevada) to California, Nevada and New Mexico; migrates S to Mexico (S to Michoacán).
M. a. ater (Boddaert, 1783) – breeds from SE Canada (S Ontario E to Newfoundland) S throughout E USA to C Texas, Gulf Coast and C Florida, and in E Mexico S to Tamaulipas; winters in Florida and in Mexico S to Oaxaca.
Also breeds in Yukon (NW Canada); race undetermined, possibly *artemisiae*.



Descriptive notes. Male 18–20 cm, female 16–18 cm; male 43·1–57·3 g and female 32·3–42·3 g (nominate), male average 47·5 g and female average 37·6 g (*artemisiae*), male average 40·2 g and female average 32 g (*obscurus*). Male nominate race has dark brown hood down to upper mantle and central chest, followed by a band of blackish feathers with purple iridescence, rest of plumage black with greenish iridescence; iris deep brown; bill and legs blackish. Female is brownish overall, darker on upperparts, and with indistinctly paler superciliary line; a shade lighter below, palest on throat; bare parts as for male. Juvenile is brownish like female, but feathers of upperparts edged buff, throat greyish-white to buff-white, and underparts streaked dusky brown. Races differ mostly in size and in female plumage: *artemisiae* is larger and longer-billed than nominate, female paler, some juveniles much paler and with prominent pale edgings above (looking scaly) and bold streaking below; *obscurus* is smallest, female slightly paler than previous (despite scientific name), some juveniles very pale and scaly like those of previous. Voice. Male song, from perch, consists of two low-pitched warbles (or a series of clicks) followed by thin descending whistle, often transcribed as "glug-glug-gliii"; in W (race *obscurus*), whistle preceded by somewhat longer series of low notes. Males also produces high-pitched flight call of 2–5 whistles, varying geographically, in W (*artemisiae*) consists of several whistles. Female call a dry chattery warble or rattle.
Habitat. Found in almost all open habitats, such as grasslands, pastures, woodland edge, agricultural fields, orchards, suburban areas and in towns. Lowlands to mountains; race *artemisiae* up to c. 3000 m.
Food and Feeding. Feeds on insects and other arthropods; also on seeds of both wild and cultivated plants. Forages on ground, often around grazing mammals, originally mostly American bison (*Bos bison*) herds and wapiti (*Cervus canadensis*) when available, nowadays exploiting domestic livestock for same purposes. Foraging sites often distant (up to 15 km) from breeding sites. Forages in small to large flocks; in non-breeding season commonly mixes with other icterids, and roosts in huge numbers (hundreds of thousands) with them and Common Starlings (*Sturnus vulgaris*).
Breeding. Season mid-Apr to mid-Jul, with some local variations. Mating system variable, from monogamy to promiscuity. A generalized brood parasite, c. 220 host species reported, of which 144 known to rear cowbird chicks; hosts mostly passerines in size range 10–150 g, frequently tyrant-flycatchers (Tyrannidae), vireos (Vireonidae), New World warblers (Parulidae), American sparrows (Emberizidae), and other icterids; certain hosts, particularly large species with long bill, recognize and remove parasite eggs; in study during 2002–2007 breeding seasons, at Konza Prairie Biological Station, in NE Kansas (C USA), 54·4% of 2621 nests of 22 passerine species that typically accept parasite eggs were parasitized by present species, and parasitized nests contained average of 1·9 parasite eggs, nestlings or both (55·7% of such nests received two or more eggs), with Bell's Vireo (*Vireo bellii*) and Dickcissel (*Spiza americana*) parasitized at much greater rate (respectively, 70·5% and 69·6%) than *Agelaius phoeniceus* (21·9%), these three species combined accounting for 85·8% of potential host nests found in all years. Female reported as producing up to 40 eggs per season (up to 77 in captivity); female regularly damages (punctures) or removes host eggs from nest; eggs usually do not resemble those of host, and have thicker shell, white to greyish-white with brown and grey spots, mean dimensions 21·45 × 16·42 mm (nominate race), 21·8 × 16·8 mm (*artemisiae*) and 19·3 × 14·99 mm (*obscurus*); incubation period for single egg 10–11 days, shorter than that of most host eggs; chick of present species does not particularly resemble those of most hosts in appearance or voice, but commonly solicits more food, leaves nest at 8–13 days.
Movements. Short-distance to medium-distance migrant. W race *obscurus* migrates S into Baja California; *artemisia* and nominate migrate mostly to S USA and Mexico (S to Michoacán and Oaxaca). Diurnal migrant. N populations leave breeding grounds in Sept–Oct; individuals ringed in NE USA travelled up to 850 km S. Returns late Mar to mid-May; males arrive back on breeding grounds a few days before females. Altitudinal movements occur in Rocky Mts and in SW USA (Sierra Nevada). Nominate race has occurred as a vagrant on many Caribbean islands, in Belize, and exceptionally in W Europe (Scotland, England, Wales, Norway).
Status and Conservation. Not globally threatened. Common to locally abundant in most of range. At end of 20th century, estimated global population was 20,000,000–40,000,000 individuals. Before European settlement was found mostly in Great Plains of C North America, and still particularly abundant there. Populations of this species usually increase and expand with human-made disturbances and forest clearance. Increases can adversely affect survival of some host species. Host nests may produce fewer (or even none) of their own chicks when parasitized, and present species can therefore threaten survival of rare and sensitive hosts. For example, Kirtland's Warbler (*Dendroica kirtlandii*), a Near-threatened species breeding just S of Great Lakes in Michigan, was considered globally threatened until, in 1970s, trapping of present species in the region reduced parasitism of the warbler's nests from 70% to only 3%; similarly, population control practised in critical areas has aided conservation efforts, e.g. control of present species within Texas range of Vulnerable Black-capped Vireo (*Vireo atricapilla*) helped the vireo to survive.

76. Shiny Cowbird

Molothrus bonariensis

French: Vacher luisant **German**: Seidenkuhstärling **Spanish**: Tordo Renegrido
Other common names: Glossy Cowbird

Taxonomy. *Tanagra bonariensis* J. F. Gmelin, 1789, Buenos Aires, Argentina.
Closely related to *M. ater*, and much resembling it in habits, general behaviour and voice. Proposed race *melanogyna* (Paraná, Brazil), with females blackish (almost as black as males), now considered a dark colour morph of nominate, as also is proposed race *milleri* (Mato Grosso, Brazil). Origin of isolated Chilean population of nominate race uncertain; analysis of mitochondrial DNA desirable. Seven subspecies recognized.
Subspecies and Distribution.
M. b. minimus de Dalmas, 1900 – SE USA (Florida), West Indies, Trinidad and Tobago, the Guianas and extreme N Brazil (R Branco).
M. b. cabanisii Cassin, 1866 – E Costa Rica, Panama and W Colombia.
M. b. venezuelensis Stone, 1891 – N Venezuela and E Colombia.
M. b. aequatorialis Chapman, 1915 – SW Colombia and W Ecuador.
M. b. occidentalis Berlepsch & Stolzmann, 1892 – extreme SW Ecuador (Loja) and W Peru.
M. b. riparius Griscom & Greenway, 1937 – E Ecuador, E Peru, and Amazon Valley in Brazil (E to Obidos).
M. b. bonariensis (J. F. Gmelin, 1789) – C & E Brazil (S of R Amazon) S to E Bolivia, Paraguay, Uruguay and Argentina (S to C Santa Cruz); also Chile (Coquimbo Region S to Aysén).

Descriptive notes. 17–21·5 cm; male average 55·7 g and female 44·9 g (nominate, E Argentina), male average 63·7 g and female 55·6 g (*cabanisii*, Colombia), male average 38·7 g and female 31·9 g (*minimus*, Puerto Rico). Male nominate race is glossy blue-black to violet-black, with wing and tail glossed bluish and greenish; ultraviolet reflectance considerable; iris brown; bill and legs blackish-grey. Differs from similar *M. rufoaxillaris* in having stronger gloss, shorter wing, longer and less deep-based bill, also diagnostic voice. Female is dusky brownish-grey above, sometimes with slight bluish gloss, and with indistinct pale supercilium, paler below, palest on throat, with faint streaking on breast, bare parts as for male; some individuals almost as black as male, but less glossy ("*melanogyna*"). Juvenile resembles female. Races differ mainly in size and in plumage gloss: *minimus* is smallest, male with more developed purple gloss than nominate, female plumage similar to nominate; *venezuelensis* resembles previous, but is noticeably larger; *cabanisii* is largest race, plumage similar to last, but male more purple, female a little paler; *aequatorialis* male has violaceous iridescence, females dark brown above and below and lacks pale supercilium; *occidentalis* is slightly smaller than previous, male with strong purplish gloss, female much paler than other races, with more developed supercilium, streaked underparts, contrastingly pale belly; *riparius* male is like nominate, but smaller, female darker above and paler below (more contrasty) than nominate. Voice. Male has "gurgling" song with 2–6 low-pitched gurgles followed by thin whistles or warbles; another song (often used in flight) is a fast, high-pitched warbling and twittering, introduced by thin descending whistle (probably homologous with flight whistles of *M. aeneus* and *M. ater*). Female song a rattle. Common call "chuck", by both sexes. Chicks beg with high-pitched, hissing whistles.
Habitat. Found in almost all open habitats, avoiding unbroken forest and dense woodland. Habitats include savannas, pastures, wetlands, farms, agricultural land, parks and gardens, including in towns and large cities. Well adapted to man-made environments, and commonly seen at roadsides. Lowlands to 3500 m.
Food and Feeding. Diet mostly insects and seeds. Feeds on both wild and cultivated seeds. Reported as taking nectar from flowers of the vine *Combretum lanceolatum*, also from cultivated plants such as eucalypts (*Eucalyptus*), *Grevillea* and *Phormium*. Forages for insects around grazing mammals, originally using native deer, capybaras (*Hydrochoerus hydrochaeris*) and other species; nowadays exploits domestic livestock for same purposes. In SE Brazil (E São Paulo), this was one of ten species attracted to activities of a mechanical lawnmower; it foraged for seeds in drying grass. Forages in small to large groups; often collects in large roosts, especially outside breeding season.
Breeding. Season Mar–Oct in Puerto Rico, May–Sept in Venezuela and Sept–Feb in N half of Argentina. Mating system apparently variable, partners sometimes temporarily monogamous, sometimes exhibit considerable amount of promiscuity. Male puffs body feathers and bows while singing. A generalist brood parasite with 240 recorded host species, most of them passerines; passerine families more frequently parasitized include tyrant-flycatchers (Tyrannidae), mockingbirds (Mimidae), thrushes (Turdidae), New World warblers (Parulidae) and New World sparrows (Emberizidae), as well as other icterids; in some host populations more than 70% of nests parasitized; several host species, particularly those having large body size or long bill, selectively remove present species' eggs from nest, and others may desert parasitized nests or bury parasite eggs beneath new lining material; host nests receive 1–20 or more eggs, often from several females, and female regularly damages (punctures) or removes host eggs (and also other parasite eggs), having major effect on host's reproduction rate. Some eggs may resemble host eggs, but no regular mimicry; eggs usually more rounded and harder-shelled than host eggs, highly variable within and among populations, from plain white (particularly in E Argentina) to pale grey or pale blue with heavy spotting and blotching in dark brown, bluish-grey and violaceous, also unspotted bluish eggs reported for race *occidentalis*, mean dimensions 22·6 × 18·1 mm in nominate form (C Argentina), 24·3 × 19·5 mm (*cabanisii*) and 20·6 × 16·5 mm (*minimus*); incubation period for single egg 11–12 days; nestling period usually 12–14 days. Although present species' nestlings and fledglings do not mimic host chicks in plumage or voice, there is little evidence of discrimination by foster-parents; survival of cowbird chicks as opposed to host chicks is strongly linked to relative sizes.
Movements. Chiefly resident. In Argentina a partial short-distance migrant, with extensive overlap of breeding and non-breeding ranges; one ringed individual recaptured c. 500 km from ringing site. Scarce during winter in extreme S of range (Argentinian Lake District). Altitudinal movements probable in S Andes of Argentina and Chile. Many records in USA N of breeding area, most along E coast N to New Brunswick (Canada); presumed due to prospecting individuals.
Status and Conservation. Not globally threatened. Common to very common throughout most of range; uncommon and local in Amazonian lowlands. Rather an aggressively spreading species, thriving in modified environments. Throughout 20th century, extended its range N from N South America, ultimately colonizing all Caribbean islands N to Bahamas and Cuba, and reaching S USA (Florida) in mid-1980s; probably expanding into other S states. Origin of isolated Chilean population of nominate race uncertain, and has been suggested that it derived from escaped Argentinian cagebirds; analysis of mitochondrial DNA may shed some light on this. Present species' parasitic habits may be causing population declines in rare host species, such as *Agelaius xanthomus* in Puerto Rico; it is now trapped on that island in an effort to control its numbers.

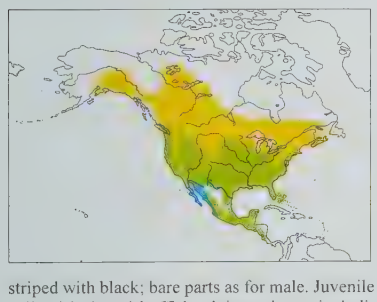
PLATE 79

inches 4

cm 10



Genus *AGELAIUS* Vieillot, 1816

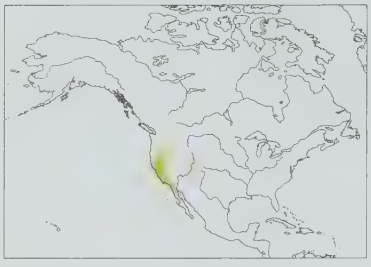
77. Red-winged Blackbird

Agelaius phoeniceus

French: Carouge à épaulettes **German**: Rotflügelstärling **Spanish**: Sargento Alirrojo
Other common names: Bicolored Blackbird ("*gubernator* group")

Taxonomy. *O.*[*riolus*] *phoeniceus* Linnaeus, 1766, Charleston, South Carolina, USA.
Formerly treated as conspecific with *A. assimilis*, but the two differ markedly in sexual dimorphism, in mating and nesting behaviour and in size; molecular data support treatment as separate species. Subspecific taxonomy complex. Distinctive race *gubernator* has been suggested as being a separate species (sometimes including *californicus* and *mailliardorum* as races); was possibly isolated in the past, but now intergrades with *nelsoni*. Over most of E USA and Canada geographical variation runs along smooth clines, and delimitation of races is rather arbitrary; several independent studies indicate minimal differences in mitochondrial DNA between most races in E North America. Some authors suggest that *arctolegus* and *fortis* are better synonymized with nominate. Additional proposed races are, in USA, *stereus* (described from Barr, Colorado), *zastereus* (from Boise, Idaho) and *heterurus* (from Fort Wingate, New Mexico), all tentatively included in *fortis*; and *matudae* (from Palizada, in Campeche, in Mexico) and *brevirostris* (from W Honduras), all treated as synonyms of *richmondi*. Twenty-two subspecies currently recognized.
Subspecies and Distribution.
A. p. arctolegus Oberholser, 1907 – breeds from SE Alaska and W Canada (SE Yukon, C Mackenzie, NW Saskatchewan and NC Manitoba S to C British Columbia, S Alberta and W & NE Ontario) S in USA to E Montana, S South Dakota and Iowa; migrates to S USA.
A. p. caurinus Ridgway, 1901 – SW Canada (British Columbia) S along US coast to N California.
A. p. nevadensis Grinnell, 1914 – breeds from SC & SE British Columbia S in W USA (from C Washington, N Idaho and WC Oregon) to SC California and S Nevada.
A. p. mailliardorum van Rossem, 1926 – C coastal California, in SW USA.
A. p. californicus Nelson, 1897 – C California (Central Valley).
A. p. aciculatus Mailliard, 1915 – Kern County, in S California.
A. p. neutralis Ridgway, 1901 – S coastal California and extreme NW Mexico (N Baja California).
A. p. sonoriensis Ridgway, 1887 – SW USA (extreme S Nevada, SE California and Arizona) and NW Mexico (N Sonora).
A. p. fortis Ridgway, 1901 – breeds in USA E of Rocky Mts (in W Montana and SE Idaho E to W Nebraska and W Kansas, S to C & EC Arizona, C & SE New Mexico and N & W Texas); N populations migrate S to Gulf Coast.
A. p. phoeniceus (Linnaeus, 1766) – breeds from SE Canada (S Quebec E to W Newfoundland and Nova Scotia) and E USA (E from Wisconsin, Iowa and E Nebraska, S to NE Texas, NE Louisiana and C Florida); N populations migrate S to at least Gulf Coast.
A. p. littoralis A. H. Howell & van Rossem, 1928 – coast of Gulf of Mexico from Texas E to Florida.
A. p. mearnsi A. H. Howell & van Rossem, 1928 – SC Florida.
A. p. floridanus Maynard, 1895 – S Florida (including Florida Keys).
A. p. bryanti Ridgway, 1887 – NW Bahamas.
A. p. nyaritensis Dickey & van Rossem, 1925 – Pacific coast from W Mexico (S from Nayarit) S to W El Salvador.
A. p. gubernator (Wagler, 1832) – C Mexico, from Durango S to Jalisco and Puebla.
A. p. nelsoni Dickerman, 1965 – Morelos and Puebla, in SC Mexico.
A. p. grinnelli A. B. Howell, 1917 – El Salvador to NW Costa Rica (Guanacaste).
A. p. megapotamus Oberholser, 1919 – S Texas (extreme S USA) and E Mexico (S to N Veracruz).
A. p. richmondi Nelson, 1897 – S Veracruz S to N Costa Rica (Limón).
A. p. pallidulus Van Tyne & Trautman, 1946 – N Yucatán Peninsula, in SE Mexico.
A. p. arthuralleni Dickerman, 1974 – L Petén Itzá, in N Guatemala.

Descriptive notes. Male average 22·7 cm, 63·6 g; female average 18·5 cm, 41·5 g. Male nominate race is almost entirely dull black, with lesser upperwing-coverts red, median coverts yellowish-buff; in non-breeding season black feathers strongly tipped pale buff to chestnut, especially on upperparts, and red epaulet feathers largely obscured by buffish tips; iris dark brown; bill and legs black. Female is dark brownish above, with conspicuous pale supercilium, upperparts streaked buff and reddish-brown; pale pinkish-buff submoustachial stripe and chin, contrasting dark malar stripe; underparts pale buff, boldly striped with black; bare parts as for male. Juvenile resembles female, but pale areas generally more yellowish, broad buffish edgings above, including wing feathers, pale base of lower mandible; immature male streaked like female, but blackish overall, and showing small epaulet. Races differ mainly in size and in female plumage tones: *fortis* is largest in size; *arctolegus* is almost as large as previous, but female darker below; *mearnsi* is similar to nominate, but smaller, with longer and more slender bill; *floridanus* is similar to last, but female paler; *bryanti* resembles previous, but female still paler; *littoralis* female is darker than nominate (and other E races), with shorter wing and tail, thinner bill; *megapotamus* has longer wing and shorter bill than nominate, female much paler and greyer than previous; *richmondi* female has more reddish plumage, more ochraceous in underparts, streaking narrower; *pallidulus* female is paler and more heavily streaked below than last; *arthuralleni* female is darker and more richly coloured than preceding race, also streaking below is heavier and blacker; *caurinus* male has median upperwing-coverts darker buff-ochre than other races, female is very richly coloured, with rusty fringes on upperparts, buffy and well streaked below; *nevadensis* has stouter bill than last, female less richly coloured; *sonoriensis* female is paler and less buffy than *caurinus*, bill relatively slender; *neutralis* is smaller and thicker-billed than last, female darker and with more streaked underparts; *aciculatus* resembles previous, but larger and with bill longer and more slender, female intermediate in colour between previous and *nevadensis*; *nyaritensis* female is paler than *sonoriensis*, and less richly coloured than *richmondi*; *nelsoni* is very like last, but with longer bill and tail; *grinnelli* female is intermediate in dorsal coloration between *nyaritensis* and *richmondi*, ventrally resembling latter; *gubernator* male has lesser upperwing-coverts orange-red (a few paler feathers on lower edge), median coverts black (not buff), female uniformly sooty grey to dull black (similar to male) with streaked paler chin and throat, reddish tinge on lesser coverts; *californicus* is like previous but smaller, with thinner bill, female more visibly streaked; *mailliardorum* has smaller bill than last, female darker. Voice. Male song variable, consists of a few short notes followed by a long and loud nasal trill, sometimes (e.g. Florida) ending in shorter trill, can be transliterated as "kon-ka-rééé" or "ko-kla-rééé-a". Songs of male *gubernator* simpler and less musical. Female has two song types: one, a chatter or "rattle", addressed to males, particularly territory-owner, and can be combined with male song in a duet; "growl", a series of harsher notes, is mostly aggressive and addressed to nearby females. Calls include low "chek" or "kek"; alarm a buzzing "zeer" or whistled "cheet", also descending "teeew".
Habitat. Marshes, ponds, roadside ditches, wet meadows, rice fields and other agricultural land, and suburban parks. Sea-level to c. 3000 m.
Food and Feeding. Seeds, also insects and other arthropods. Takes seeds of both wild plants, e.g. water grasses (*Echinochloa*) and filarees (*Erodium*), and cultivated ones, including rice, maize (*Zea mays*), sorghum and sunflower (*Helianthus*). Chicks in North American wetlands provisioned mostly with emerging damselflies and dragonflies (Odonata). Forages on ground and low in vegetation. Often turns over stones and dry dung to find hidden prey. Forages in huge flocks, sometimes of hundreds of thousands of individuals; in non-breeding season commonly in single-sex flocks. Roosts gregariously, often with other icterids and Common Starlings (*Sturnus vulgaris*).
Breeding. Season Mar–Jul in most of North America and Apr–Aug (sometimes to Nov) in Costa Rica. Mostly polygynous, ranging from sequential polygyny (in upland habitats with poorer food supplies) to harem polygyny (in highly productive marshes); highest level of polygyny (ten or more nesting females per territorial male, with record of 33) in very productive wetlands of W North America, elsewhere normally 2–4 females per male; female regularly indulges in extra-pair copulations, and 23–48% of nestlings sired by males other than partner (usually territorial neighbours). Dominant male defends territories where females build nests; females may defend smaller areas within male's territory, but defence often weak. Nest built by female, usually taking 3 days, an open cup of diverse plant materials, mixed with some mud or peat, lined with finer material, often dry grass, external diameter c. 12 cm, external depth 11–12 cm, placed from 25 cm to c. 3 m above ground in emergent marsh vegetation, often in cat-tails (*Typha*) or sedges (Cyperaceae), sometimes on dry soil in diverse herbaceous plants, or in shrub e.g. *Baccharis* or poison oak (*Rhus*), or in low tree such as alder (*Alnus*) or willow (*Salix*). Clutch 3–5 eggs in North America, 2–3 in Costa Rica, pale greenish-blue with dark blotches, spots and lines, mean dimensions 24·8 × 17·6 mm (USA); incubation by female, period 12–14 days; chicks provisioned mostly or exclusively by female, male may contribute in some situations (related to brood size and nestling age), nestling period 10–12 days; fledglings fed for about two weeks, male helping far more frequently. Nests parasitized by *Molothrus ater*, less frequently by *Molothrus aeneus*, and in SE USA (Florida) possibly also by *Molothrus bonariensis*.
Movements. Populations in W USA, Mexico and farther S are mostly resident. Those in N & E North America (races *arctolegus*, *fortis* and nominate) migratory, during boreal winter reaching Gulf states from extreme S Texas E to Florida. Departure from breeding grounds in Aug–Sept in extreme N of range, in Oct farther S, reaching non-breeding quarters from about Nov; return begins in Feb–Mar, arrival in far N of breeding range in May. Some races (e.g. *nevadensis*) partially migratory, some moving relatively short distances. US ringing data show that not all movements are on a N–S axis, as some also E to W or vice versa; ringed individuals moved distances of 600–1000 km, females moving 200–300 km farther than males; individual may change their wintering locations from one year to another.
Status and Conservation. Not globally threatened. Common to very common, and locally abundant. Global populations estimated at minimum of 200,000,000 individuals. Found in many modified environments. Commonly regarded as an agricultural pest, particularly of maize and sunflower, in Canada and USA; diverse control measures employed, ranging from direct shooting to poisoning and sterilization, while "environmentally friendly" methods include the creation of damage-resistant cultivars of the plants attacked. On the other hand, this species is beneficial to humans as it also feeds on insects that attack cultivated plants. Some distinctive races in Mexico and Central America may be of local conservation concern; further study required.
Bibliography. Albers (1978), Alcock (1973), Armstrong (1995), Ball *et al.* (1988), Beletsky (1983, 1996), Beletsky & Orians (1987a, 1987b, 1989, 1996), Bendell *et al.* (1981), Bird & Smith (1964), Blakely (1975), Blankespoor *et al.* (1982), Bollinger (1985), Bollinger & Caslick (1985), Bray *et al.* (1975), Brenowitz (1982), Brugger & Dolbeer (1990), Buford *et al.* (1998), Caccamise (1977), Clark *et al.* (1986), Clotfelter & Yasukawa (1999a, 1999b), Cox & James (1984), Dickerman (1974), Dickinson & Lein (1987), Dolbeer (1976, 1978), Dyer (1975), Eckert & Weatherhead (1987), Fiala (1981), Gibbs *et al.* (1990), Gray (1997a, 1997b), Hardy (1967), Hardy & Dickerman (1965), Holcomb & Twiest (1970), Howell & Webb (1995), Hurly & Robertson (1984, 1985), James (1983), Jaramillo & Burke (1999), Knight & Temple (1988), Kroodsma & James (1994), Lacombe & Bergeron (1986), Mah & Neuchterlein (1991), Marchant (1960), McCarthy (2006), McGuire (1986), Nero (1984), Orians (1973), Orians & Beletsky (1989), Orians & Christman (1968), Patterson (1991), Payne (1969), Peek *et al.* (1972), Picman (1981, 1983), Power (1970), Rohwer *et al.* (1996), Scott (1991), Searcy (1979, 1986), Searcy & Yasukawa (1981, 1995), Searcy *et al.* (1999), Smith (1972), Stevenson & Anderson (1994), Stowers *et al.* (1968), Strehl & White (1986), Teather (1993), Weatherhead & Clark (1994), Weatherhead & Robertson (1977), Weatherhead *et al.* (1982), Webster (1999), Westneat (1993, 1995), Whittingham *et al.* (1992), Yasukawa & Searcy (1981, 1995), Yasukawa, Blank & Patterson (1980), Yasukawa, Boley & Simon (1987), Yasukawa, McClure *et al.* (1990).



78. Tricolored Blackbird

Agelaius tricolor

French: Carouge de Californie **German**: Dreifarbenstärling **Spanish**: Sargento Tricolor

Taxonomy. *Icterus tricolor* Audubon, 1837, no locality = Santa Barbara, California, USA.
Closely related to *A. phoeniceus*. Monotypic.
Distribution. W USA (S Washington, Oregon, California W of Sierra Nevada, also extreme SW Nevada) and extreme NW Mexico (extreme N Baja California).
Descriptive notes. Male average 22·3 cm, 60–79 g; female average 18·5 cm, 46–54·5 g. Male is black with slight bluish gloss, lesser upperwing-coverts crimson-red, median coverts contrastingly white;

On following pages: 79. Red-shouldered Blackbird (*Agelaius assimilis*); 80. Tawny-shouldered Blackbird (*Agelaius humeralis*); 81. Yellow-shouldered Blackbird (*Agelaius xanthomus*); 82. Colombian Mountain Grackle (*Macroagelaius subalaris*); 83. Tepui Mountain Grackle (*Macroagelaius imthurni*); 84. Velvet-fronted Grackle (*Lampropsar tanagrinus*); 85. Oriole Blackbird (*Gymnomystax mexicanus*); 86. Red-bellied Grackle (*Hypopyrrhus pyrohypogaster*); 87. Austral Blackbird (*Curaeus curaeus*); 88. Forbes's Blackbird (*Curaeus forbesi*); 89. Scarlet-headed Blackbird (*Amblyramphus holosericeus*); 90. Chopi Blackbird (*Gnorimopsar chopi*).

in non-breeding season black body feathers tipped light grey-brown, especially on back, epaulet less striking; iris brown; legs and bill black. Differs from very similar *A. phoeniceus* mainly in having white (not buff) median coverts, also glossier plumage, somewhat longer, thinner bill. Female is dusky brown overall, streaked with blackish; chin and throat whitish, sometimes a pale supercilium; more uniformly dark than female *A. phoeniceus*. Juvenile resembles female, but plumage somewhat duller and more buffish-looking. Voice. Song of male is a harsh, unmusical growl, "grroowak", which lasts 1–1·5 seconds, lower-pitched than song of *A. phoeniceus*. Female song a hollow chatter or rattle. Common calls "churr" and "chwuk".

Habitat. Natural habitat probably marshes and ponds with cat-tails (*Typha*) and bulrush (*Scirpus*), and nearby grassland. Nowadays found also in pastures, feedlots, rice fields and other irrigated agricultural land. Lowlands to 1300 m.

Food and Feeding. Insects and other arthropods, and seeds (including rice and other cereals). Insects include beetles (Coleoptera), larval moths and butterflies (Lepidoptera) and grasshoppers (Orthoptera), also larvae of caddis flies (Trichoptera), dragonflies (Odonata) and midges (Diptera); opportunistic, attracted to insect swarms, and probable that swarms of migratory locusts (now gone) provided much food in the past. Gregarious throughout year. Forages on ground, in huge flocks of tens of thousands, the two sexes moving together; sometimes in mixed-species foraging flocks with *A. phoeniceus*. Gathers almost all of the food for young outside the colony.

Breeding. Season Mar/Apr–Jul, starting first in foothills and latest in rice fields, also some autumnal breeding Oct–Nov; egg-laying often highly synchronized, even in colonies of 50,000 or more nests all females may lay within period of one week; some suggestive evidence of itinerant breeding, i.e. individuals nest more than once in a season, but at different localities (an entire nesting cycle may take only 42 days). Monogamous to moderately polygynous, with 1–4 nesting females per territorial male. Breeding territory quite small, 2–3 m². Nests in huge, densely packed colonies (largest reported for any icterid), usually of 1000–50,000 nests, and reported maximum of 200,000 nests (numbers of breeders at particular site can change dramatically between years); a colony of 100,000 nests occupied only 4 ha; colonies located in three main habitats, i.e. non-irrigated uplands or foothills, irrigated agricultural areas without rice, and rice fields. Through sheer numbers may easily displace *A. phoeniceus* from a Californian marsh. Nest built by female, an open cup of diverse plant materials, mixed with some mud, lining usually of green grass, placed low in marsh vegetation (often in cat-tails), or on dry soil in herbaceous plants (even weeds such as thistles, or cultivated alfalfa), sometimes on ground, or up to 3 m above it in willow (*Salix*); a favourite nesting plant in uplands is introduced Himalayan blackberry (*Rubus discolor*). Clutch 3–6 eggs, usually 4, pale greenish-blue with brown to black spots and lines, mean dimensions 24·4 × 17·7 mm; incubation by female, period 11–12 days; chicks fed by female, nestling period 12–13 days; males commonly feed fledged chicks, which collect in groups. Nests parasitized rarely by *Molothrus ater*. Usually 1–3 fledglings produced per nest; reproductive success much higher in non-native upland vegetation (mainly Himalayan blackberry) than in native wetland vegetation (cat-tail and bulrush stands); often extremely low in silage fields (which hold significant proportion of breeding population), where harvesting can result in loss of entire colonies; some colonies in non-irrigated land may be entirely abandoned during unusual droughts.

Movements. Resident to nomadic; populations move within the species' range in response to weather conditions and food supply. Possibly followed migratory locust in the past. In coastal California, appears to be more abundant in winter than at other times.

Status and Conservation. ENDANGERED. Restricted-range species: present in California EBA. Classified as "Highest Concern" in the USA (Red WatchList priority species for conservation). Rare to locally common; more than 95% of the population breeds in the state of California, where found mostly in Central Valley. Global population in 2010 estimated at 395,000 individuals; earlier, minimum of 700,000 adults estimated in 1934 in just eight counties in California. In later surveys covering whole of California, 370,000 estimated in 1994, 233,000 in 1997 and 162,000 in 2000, representing a decline of 56% in period of only six years; in 2005, however, as many as 257,000 individuals found at total of 21 colonies, suggesting that caution required in assessing and comparing survey figures. Formerly bred in colonies containing hundreds of thousands of individuals, but since c. 1900 numbers drastically reduced as a result of human activities; populations have declined steadily because of massive loss of nesting habitat in California, also because of agricultural practices, such as harvesting and pesticide-spraying, that disrupt or destroy colonies. During Christmas Bird Count, this species has been recorded regularly at 120 sites for almost 40 years, suggesting that population may be relatively stable. Considerable variation in population estimates indicates that it is a very difficult species to survey, and a thorough and constant, reliable methodology is required in the future. Few details available on the species' status away from California. Formerly regarded as a pest, and until 1960s was killed by poisoning.

Bibliography. Anon. (2010d), Beedy & Hamilton (1999), Bent (1958), Churchwell *et al.* (2005), Cook & Toft (2005), Crase & DeHaven (1977), DeHaven *et al.* (1975a, 1975b), Emlen (1941, 1985), Hamilton (1998), Howell & Webb (1995), Jaramillo & Burke (1999), Lack & Emlen (1939), Lebbin *et al.* (2010), Neff (1937, 1942), Orians (1960, 1961), Orians & Christman (1968), Orians & Collier (1963), Payne (1969), Payne & Landolt (1970), Rich *et al.* (2004), Richardson (1961), Skorupa *et al.* (1980).

79. Red-shouldered Blackbird

Agelaius assimilis

French: Carouge de Cuba **German**: Rotschulterstärling **Spanish**: Sargento Cubano

Taxonomy. *Agelaius assimilis* Lembeye, 1850, Cuba.

Formerly treated as conspecific with *A. phoeniceus*, but the two differ markedly in sexual dimorphism, in mating and nesting behaviour and in size; molecular data support treatment as separate species. Birds from I of Pines formerly separated as a geographical race, *subniger*, but description was based on immature specimens. Monotypic.

Distribution. W Cuba, including I of Pines.

Descriptive notes. Male average 22 cm, 54·4 g, female average 20 cm, 41·8 g. Male is black with slight bluish gloss; lesser upperwing-coverts red, median coverts yellow-buff; iris dark brown; bill and legs black. Differs from extremely similar *A. phoeniceus* in smaller size and longer legs. Female is entirely black, like male, but less iridescent, and lacking coloured epaulets. Immature male has epaulet reduced in size and paler; immature female more brownish. Voice. Song described as a repeated rather shrill creaking "o-wi-hiii", similar to that of *A. phoeniceus* but higher-pitched and shorter, and produced by both sexes, sometimes in duet. Call "chuk" or "chek", sometimes in short series.

Habitat. Breeds in swamps and marshes, generally in sites with cat-tails (*Typha*), bulrushes (*Scirpus*) and similar tall emergent vegetation. In non-breeding season forages also in nearby uplands, including pastures and agricultural fields.

Food and Feeding. Insects and other arthropods, small vertebrates, fruits and seeds; also discarded food scraps. Forages mostly on ground. Forms flocks, sometimes quite large ones; often associates with *A. humeralis* and *Ptiloxena atroviolacea*.

Breeding. Season Apr/May–Aug. Monogamous. Territorial, territories c. 700–900 m² in extent. Nest built by female, cup-shaped, made from dry grass, feathers, hair, etc., external diameter 9–10 cm, internal depth 5–6·6 cm, placed low down in aquatic vegetation such as beak-sedge (*Rhynchospora*), cat-tails, reeds (*Phragmites*) or arrowhead (*Saggitaria*) in swamp or marsh. Clutch 2–3 eggs, bluish-white with brown and pale purple spots, mean dimensions 24·6 × 17·5 mm; incubation by female, chicks fed by both sexes (at similar frequencies); no information on duration of incubation and nestling periods.

Movements. Apparently resident.

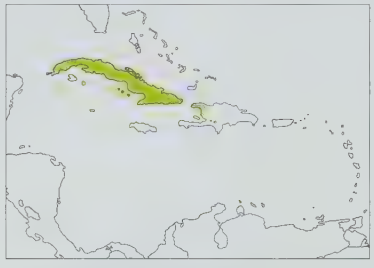
Status and Conservation. Not globally threatened. Locally common. Has restricted and fragmented distribution. Very numerous at Ciénaga de Zapata. Recently reported from region of Ciego de Ávila, in SC Cuba; further study needed. Fragmented range a reflection of very patchily distributed habitat.

Bibliography. Balát & González (1982), Barbour (1943), Barker *et al.* (2008a), Beletsky (1996), Davis, M. (1953), Garrido (1970), Garrido & Kirkconnell (1996), Jaramillo & Burke (1999), Raffaele *et al.* (1998), Whittingham *et al.* (1992, 1996, 1997).

80. Tawny-shouldered Blackbird

Agelaius humeralis

French: Petit Carouge **German**: Braunschulterstärling **Spanish**: Sargento Humeral



Taxonomy. *Leistes humeralis* Vigors, 1827, Havana area, Cuba.

Closely related to and possibly forming a superspecies with *A. xanthomus*. Two subspecies recognized.

Subspecies and Distribution.

A. h. humeralis (Vigors, 1827) – Cuba, including larger cays on N coast, and some outlying islands (e.g. Jardines de la Reina Archipelago); also W Hispaniola (W Haiti).

A. h. scopulus Garrido, 1970 – Cayo Cantiles (E of I of Pines), off SW Cuba.

Descriptive notes. 19–22 cm; male average 38·3 g, female average 34·5 g. Male nominate race is black, slightly glossed bluish; lesser and median upperwing-coverts tawny, median coverts tipped yellowish-cream; iris dark brown; bill and legs black. Female is like male, but duskier and without gloss; tawny shoulder patch smaller, median coverts partly black. Juvenile is dusky black, with little or no tawny in wing. Race *scopolus* is smaller and thinner-billed than nominate, and with reduced shoulder patch. Voice. Song, by both sexes, 1–2 protracted buzzing notes, sometimes introduced with shorter buzz at higher pitch; partners sometimes duet. Calls include "chuk" or "cheek", also nasal and metallic notes.

Habitat. Open woodland and woodland edge, farmland and rice fields; in Haiti occurs along sloughs and channels in dry open woodland.

Food and Feeding. Insects and other arthropods, small lizards, seeds; also fruits and nectar. Insects taken include bees (Apoidea). Forages on ground, also in bushes and trees. Forms large flocks, mainly in non-breeding season; often associates with other icterids.

Breeding. Season Apr–Aug in Cuba; fledged chicks reported May–Jul. Monogamous. Breeds solitarily, sometimes in small loose colonies; reported inter-nest distances 8–25 m, large trees may hold several active nests. Non-territorial, defends only a small area around nest. Nest built mostly by female, cup-shaped, made from dried grass, moss, twigs, hair and feathers, placed in tree or palm, usually near water, sometimes in emergent water plants in marsh; commonly builds among basal portion of frond of Cuban royal palm (*Roystonea regia*), occasionally in introduced eucalypt tree (*Eucalyptus*), and even on outdoor lamp. Clutch 3–4 eggs, bluish to greenish with brown spots, mostly at large end, mean dimensions 22·6 × 16·7 mm; incubation by female, chicks fed by both sexes (at similar rates); no information on duration of incubation and nestling periods. Nests possibly parasitized by *Molothrus bonariensis*; further study needed.

Movements. Largely resident. Some limited movement apparently; nominate race recorded as an accidental in SE USA (Florida).

Status and Conservation. Not globally threatened. Common in Cuba; uncommon and local in Haiti. In Haiti found only in W, mostly at mouth of R Artibonite, also in area of Port-de-Paix; rarely or formerly around Port-au-Prince. Haitian population first discovered in 1927, and sometimes believed the result of recent colonization from Cuba; no DNA data available to verify this idea. Adapts well to man-modified environments.

Bibliography. Balát & González (1982), Barbour (1943), Buden & Olson (1989), Demeritt (1936), Garrido (1970), Garrido & Kirkconnell (2000), Jaramillo & Burke (1999), Raffaele *et al.* (1998), Wetmore & Swales (1931), Whittingham *et al.* (1996).

81. Yellow-shouldered Blackbird

Agelaius xanthomus

French: Carouge de Porto Rico **Spanish**: Sargento Puertorriqueño
German: Gelbschulterstärling

Taxonomy. *Icterus xanthomus* P. L. Sclater, 1862, Mexico; error = Puerto Rico.

Closely related to and possibly forming a superspecies with *A. humeralis*. Two subspecies recognized.

Subspecies and Distribution.
A. x. xanthomus (P. L. Sclater, 1862) – Puerto Rico.
A. x. monensis Barnés, 1945 – Mona I, off W Puerto Rico.

Descriptive notes. 20–23 cm; male average 41 g, female average 35 g. Male nominate race is black with bluish gloss; lesser and median upperwing-coverts yellow (tips of medians sometimes paler); iris dark brown; bill and legs black. Female is similar to male, but a little smaller. Juvenile is duller than adult, more brownish-grey than blackish, with much smaller and paler shoulder patch. Race *monensis* differs from nominate in having shoulder patch paler, at times yellowish-white. Voice. Song a rasping nasal "nyaaaaaa", by both sexes, sometimes by several individuals in chorus. Common call "chuk"; alarm "ct-zeee".
Habitat. Restricted to mangroves (*Avicennia nitida*, *Rhizopora mangle*, *Laguncularia racemosa*) along coast and in small mangrove islands (cayos), pastures near mangroves, and palm plantations, including stands of Puerto Rico royal palm (*Roystonea borinquena*) and coconut (*Cocos nucifera*). On Mona I (race *monensis*) frequents coastal cliffs.
Food and Feeding. Diet mainly insects, particularly moths (Lepidoptera) and crickets (Gryllidae); takes nectar from flowers of *Erythrina*, *Inga*, *Aloe* and *Yucca*, and feeds also on cactus fruits. Forages in trees, probing and gaping among bark and epiphytes; also on ground. In small groups; larger flocks in non-breeding season.
Breeding. Season Apr–Aug; on Mona I (race *monensis*) more protracted, Feb–Nov. Monogamous. Nests in small colonies (often 4–6 nests), average inter-nest distance 16 m, in abandoned salt ponds, on small offshore islands, stands of red mangrove (*Avicennia*), trees in pastures, and palm groves, also on sea cliffs on Mona. Non-territorial. Nest built by female, cup-shaped, made from local materials as variable as grass, roots, seaweed, feathers, string, scraps of paper and plastic, lined with fine grass, placed in tree hole, in cavity or crevice in sea cliff, or in branches of red mangrove, other tree, or palm; accepts nestboxes. Clutch 1–4 eggs, usually 3, blue-green with brown spots; incubation by female, often fed by male, period 12–13 days; chicks fed by both sexes, nestling period 13–16 days. Nests often parasitized by *Molothrus bonariensis*, and rears latter's chicks.
Movements. Apparently resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA. Uncommon to rare, and local. Nominate race formerly occurred throughout Puerto Rico, where population estimated at 2400 individuals in 1975; following huge contraction of range, now confined mostly to SW coastal area; small remnant population that persisted in E coastal areas appears to have disappeared, with no breeding records since 1986. In SW Puerto Rico, declined by c. 80% between 1975 and 1981, and in 1982 numbered 300 individuals at most, but roost counts prior to breeding season during 1985–1995 revealed average annual increase of 14%. Estimated global population in early 1998 c. 1250 individuals. Population on Mona I (race *monensis*) c. 700 individuals and believed stable. Seems always to have been most numerous near coast, and many of surviving population in Puerto Rico now breed on offshore cays. One of main reasons for decline was brood parasitism by *Molothrus bonariensis*, which invaded Puerto Rico around mid-1950s or before, and may have been largely responsible for shift to cays; habitat disturbance enabled the parasite to increase and spread rapidly. Other factors include habitat clearance for agriculture, nest predation by Pearly-eyed Thrashers (*Margarops fuscatus*) and increased mortality caused by introduced carnivores; also, invasion of nesting areas by Caribbean Martins (*Progne dominicensis*). Since 1982, following installation of artificial nests, monitoring of breeding, and control of numbers of *Molothrus*, rats (*Rattus*) and nest mites (Acarina), as well as habitat management, improvement in nesting success recorded, and in SW Puerto Rico, where Boquerón Commonwealth Forest is a stronghold for this icterid, its numbers have continued to recover slowly. *Molothrus* not known to occur on Mona I.

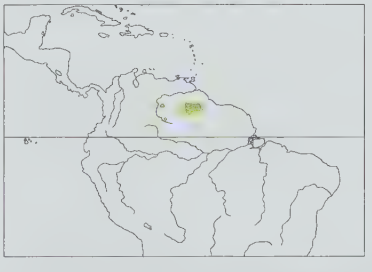
Genus *MACROAGELAIUS* Cassin, 1866

82. Colombian Mountain Grackle

Macroagelaius subalaris

French: Carouge montagnard **German**: Braunachselstärling **Spanish**: Chango Colombiano
Other common names: Mountain Grackle

Taxonomy. *Quiscalus sub-alaris* Boissonneau, 1840, Bogotá, Colombia.
Closely related to and forming a superspecies with *M. imthurni*. The two have sometimes been regarded as conspecific, but differ appreciably in body and bill proportions, plumage and vocalizations. Monotypic.
Distribution. E Andes of Colombia from Norte de Santander and Santander S on W slope to Cundinamarca.



Descriptive notes. Male 29–30 cm, female 27–28 cm. Slender and long-tailed icterid. Plumage is almost entirely black with blue gloss; axillaries and most of underwing-coverts dark chestnut (almost invisible in field); iris dark brown; bill and legs black. Differs from similar *M. imthurni* mainly in having chestnut in wing, no yellow pectoral tufts, slightly thicker bill, slimmer body. Sexes similar. Juvenile is less glossy and more dusky brown, particularly in flight-feathers, than adult, and with reduced chestnut in wing. Voice. Song variable, sometimes starting with low clicks and buzzing notes, followed by series of different warbled or whistled motifs, each one usually repeated 2–4 times; repetitive pattern makes song somewhat reminiscent of that of a mockingbird (*Mimus*). Calls include sharp "check" and "chuip" notes for contact.
Habitat. Humid upper montane forest rich in epiphytes, particularly oak forest (*Quercus humboldtii*), up to *páramo*; 1900–3100 m.
Food and Feeding. Feeds on insects and other arthropods, particularly weevils (Curculionidae), Orthoptera, bugs (Hemiptera), hymenopterans and spiders (Araneae); takes berries of *Oreopanax floribundum* (Araliaceae) and *Hedyosmum bonplandianum* (Chloranthaceae). Forages mostly at height of 15–30 m, searching for food items among leaves, inflorescences and epiphytes. Drinks from water stored in tank bromeliads. Found in groups of up to 40 individuals; sometimes in mixed-species foraging flocks with Acorn Woodpecker (*Melanerpes formicivorus*), Green Jay (*Cyanocorax yncas*), Great Thrush (*Turdus fuscater*), Hooded Mountain-tanager (*Buthraupis montana*), *Icterus nigrogularis* and *Cacicus leucoramphus*.
Breeding. Season May–Sept. Nests solitarily. Co-operative breeder, groups of 4–5 individuals attending nest or fledglings; also one adult, perhaps a breeding female, was fed by other adults from a nesting group. Nest built by several members of group, described as an open cup made from diverse plant material, two built mostly with dry leaves and branchlets of *Chusquea tesellata* bamboo, stems of *Pennisetum clandestinum* grass and dry branchlets of *Miconia*, external walls may include *Usnea* lichens, lining materials included thin fern stems and palm or bromeliad fibres, external nest diameter 25–30 cm, depth 16·5 cm, internal diameter 10–11 cm; placed mostly in oak, sometimes in *Escallonia paniculata* or *Clethra*, usually 5–10 m above ground, often on inaccessible external branch or above steep slope, some nests more or less camouflaged by arboreal leaf litter. No information on clutch size, eggshell fragments were pale blue with reddish-brown marks; no information on incubation and nestling periods; chicks fed by several group-members.
Movements. Apparently resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Colombian East Andes EBA. Rare and extremely local. Estimates of global population range from 1000 to 3000 individuals. Range formerly much wider, probably extending also to E slope. During 20th century this species was extirpated from many areas, and now has a patchy distribution. Habitat loss the main threat, as at least 80% of montane oak forests have been logged or converted to pasture. In recent surveys recorded at 22 localities, from Suratá (in Santander) S to La Aguadita (Cundinamarca), but follow-up surveys revealed that many of these were suffering rapid deforestation. During surveys in 2003–2006 in Serranía de los Yariguíes (a spur extending from main E Andean range in Santander) found at three sites, at one of which considered abundant. Yariguíes massif, a steep, forested range c. 100 km in length, still retains considerable amount of forest at elevations suitable for this icterid, and in Jan 2011 new population discovered at Reserva Páramo La Floresta (privately owned reserve administered by municipality of Zapatoca); this site, at elevation of c. 2600 m, includes second growth, sub-*páramo*, fragments of oak forest and, importantly, a *humedal* (marshy wetland), around which this icterid was the most conspicuous (and possibly most numerous) bird species. Very similar habitats exist elsewhere in Yariguíes range, but on isolated plateaux of steep forested mountains, and thus very difficult to reach; likely that these, too, support significant populations of this species. In rest of this species' range, population small and severely fragmented, and prospects for survival uncertain. Conservation efforts and ecological studies at Guanentá–Alto Río Fonce Fauna and Flora Sanctuary, in Santander, and at Soatá and Tipacoque, in Boyacá, appear to have had some success and are continuing. In addition to Reserva Páramo La Floresta, reported from Las Orquídeas, Cueva de los Guácharos and Tatamá National Park, and from Ucumarí Regional Park.
Bibliography. Amaya-Espinel & Renjifo (2002), Anon. (2010d), Butchart & Stattersfield (2004), Cadena *et al.* (2002), Cortés-Herrera, Chaves-Portilla *et al.* (2006), Cortés-Herrera, Hernández-Jaramillo *et al.* (2006), Cortés-Herrera, Ruiz-Ovalle & Hernández-Jaramillo (2011), Fierro-Calderón *et al.* (2006), Hilty & Brown (1986), Jaramillo & Burke (1999), López-Lanús (2005a), Meyer de Schauensee (1951), Renjifo *et al.* (2002), Restall *et al.* (2006), Stattersfield & Capper (2000).

83. Tepui Mountain Grackle

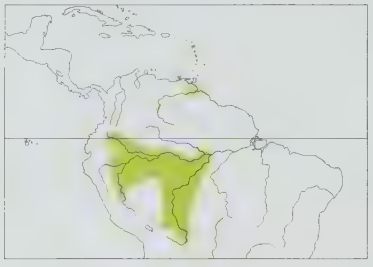
Macroagelaius imthurni

French: Carouge des tépuis **German**: Goldachselstärling **Spanish**: Chango de Tepuí
Other common names: Golden-tufted (Mountain) Grackle

Taxonomy. *Agelaeus imthurni*, P. L. Sclater, 1881, Kaieteur Falls, Potaro River, Guyana.
Closely related to and forming a superspecies with *M. subalaris*. The two have sometimes been regarded as conspecific, but differ appreciably in body and bill proportions, plumage and vocalizations. Monotypic.
Distribution. Mountains (tepuis) in S Venezuela (W & C Amazonas and SE Bolívar), extreme N Brazil (Roraima) and W Guyana.

Descriptive notes. Male 28 cm, average 87·3 g; female 25 cm, average 71·7 g. Rather slender and long-tailed icterid. Plumage is almost entirely black with blue gloss, becoming dusky or duller black on belly, rump and inner webs of flight-feathers; underwing-coverts black, axillaries yellow to tawny-yellow with variable chestnut feather bases (showing as pectoral tuft); iris hazel to dark brown; bill and legs black. Sexes similar. Juvenile is less glossy and more dusky brown, particularly in flight-feathers, than adult. Differs from similar *M. subalaris* in having yellow pectoral tufts, little or no chestnut in wing, thinner bill, somewhat less slim body. Voice. Rather noisy. Presumed song complex and variable, mixing shrill and rasping warbles with more pleasant metallic notes; one of shorter variants is "sh-glack-chak-shweo-shwéé"; longer songs may sound like series of rising and falling, dissonant chords, with glassy tone. Commonly sings in flight. Apparently both sexes sing (and duet), and group singing frequent. A common call, perhaps as alarm, is a repeated "chak". May produce audible wing noise in flight.
Habitat. Lower to upper montane humid forest with high diversity of evergreen trees such as *Eschweilera odorata*, *Guarea silvatica*, *Euterpe* palms, among others, covered with abundant bromeliads and other epiphytic plants; above 1200 m occurs in stunted forests (up to 15 m tall) on poor sandy soils, dominated by *Miconia* and other trees in family Melastomataceae, with abundance of epiphytic and terrestrial bromeliads. At 700–2000 m, occasionally down to 500 m.
Food and Feeding. Scant information. Probably eats arthropods, small vertebrates and fruit. In Sierra de Lema (Venezuela) feeds on moths (particularly of family Noctuidae) attracted to night lights; in same area a flock seen to inspect or feed on racemes of red-coloured berries produced by an abundant shrub (species not identified). Finds insect prey in foliage and in epiphytes; not reported as feeding in forest undergrowth or on ground. Occurs mostly in monospecific flocks of 10–30 individuals.

Breeding. Breeds in Mar in Venezuela. Co-operative breeder. Few nests described: one was a bulky cup 30 cm in diameter, loosely built from grasses and other plant fibres, placed 12 m up in crown of tree in group of four trees growing on a peninsula in a large river; in a similar nest found at Sierra de Lema, five adults brought food to three chicks. No further information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Locally abundant in appropriate habitat. Found in several protected areas in its range: Canaima and Duida-Marahuaca National Parks, in Venezuela, Monte Roraima National Park, in Brazil, and Kaieteur National Park, in Guyana.
Bibliography. Barnett *et al.* (2002), Fraga (2009), Hilty (2003), Jaramillo & Burke (1999), Johnson & Lanyon (1999), Meyer de Schauensee (1951), Restall *et al.* (2006), Ridgely & Tudor (1989).



Genus *LAMPROPSAR* Cabanis, 1847

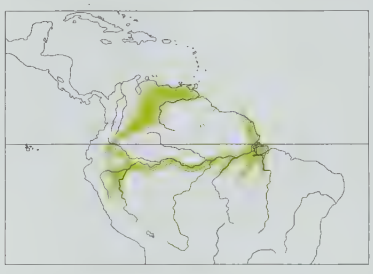
84. **Velvet-fronted Grackle**

Lampropsar tanagrinus

French: Carouge velouté **German**: Samtstirnstärling **Spanish**: Chango Terciopelo
Other common names: Bolivian Grackle (*boliviensis*); Violaceous Grackle (*violaceus*)

Taxonomy. *Icterus tanagrinus* Spix, 1824, Itacoatiara, north-east Amazonas, Brazil.
Analysis of mitochondrial DNA suggests relationship with morphologically very different *Gymnomystax mexicanus*. Some races, especially *boliviensis*, may merit full species status. Five subspecies recognized.
Subspecies and Distribution.
L. t. guianensis Cabanis, 1848 – Venezuela (Sucre and NE Monagas S to NE Bolívar; NW Amazonas) and NW Guyana, NE Colombia (NE Vichada), and extreme N Brazil (Roraima).
L. t. tanagrinus (Spix, 1824) – Amazon Basin in E Ecuador, S Colombia (Amazonas), NE Peru (Loreto and Ucayali) and W Brazil (Amazonas E to lower R Negro and R Madeira).
L. t. macropterus Gyldenstolpe, 1945 – W Brazil (upper R Juruá in Acre and W Amazonas).
L. t. violaceus Hellmayr, 1906 – WC Brazil (NW Mato Grosso).
L. t. boliviensis Gyldenstolpe, 1941 – E Bolivia (Beni and Santa Cruz).

Descriptive notes. Male average 20·3 cm, 59·4 g; female average 19 cm, 55·2 g. All-dark icterid with short, conical bill and rather long and fan-shaped tail; feathers on forehead and lores stiff and plush-like. Male nominate race is entirely black, with bluish to purple gloss on upperparts; iris dark brown; bill and legs black. Differs from *Quiscalus lugubris* in smaller size, smaller bill, eye colour, tail shape, drabber coloration, and voice. Female is similar to male, but slightly duller. Juvenile resembles adult. Race *guianensis* is smaller than nominate, has blue gloss on underparts and brownish underwing-coverts; *macropterus* is larger than nominate, tail glossed green; *violaceus* has distinctive violet iridescence; *boliviensis* is smaller than others. Voice. Rather vocal. Songs in Venezuela (nominate race) pleasant, but with slight glassy tone. Song repertoires include trills and repeated warbled phrases, mixed with calls; some themes consist of paired question-and-answer phrases, e.g. "he-you-sweet...krr-chew". Contact or alarm calls include "chuk" notes and a harsh "gk", also scolds with "trr-rrrt" mixed with soft "peet" notes; *bolivianus* also "chu-chu-chu".
Habitat. Usually near water (rivers, channels, oxbow lakes, marshes) in primary forest and secondary forest, riparian woodland and shady plantations. Also in mangroves in Venezuela and Guyana. In Amazonia occurs in *várzea* or *igapó* vegetation; in E Bolivia in seasonally flooded savanna with motacú palms (*Scheelea princeps*). Nominate race and *guianensis* up to 400 m; *boliviensis* to 500 m.
Food and Feeding. Few data on diet; stomach contents beetles (Coleoptera) and alate ants (Formicidae). Forages in lower and middle levels of vegetation, also on emergent and floating aquatic plants. Found mostly in groups of 3–10 individuals, sometimes up to 30 and exceptionally up to 100.
Breeding. Season Mar in Guyana, Sept in Ecuador, and Oct and Feb in Bolivia. Seems to be a co-operative breeder, but scant available information. A nest in Guyana was made mostly from roots, and placed in a shrub over water; in Ecuador, three individuals helped in nest-building (at least one other also visited during building stage, and five individuals reported one week later), nest was a cup 28 cm tall and with external diameter 14 cm, made from long fibrous roots, loose fibres up to 80 cm long dangling below nest, placed on drooping branch of small *Inga* tree over channel 5 m wide in flooded area; in Bolivia, one nest a rather thick, deep cup 29 cm in height, external diameter 12 cm, built from roots, slender stems and dark fungal rhizomorphs (presumably of *Marasmius*), sited 2 m above ground in orange tree in plantation. Clutch 3 eggs (Bolivia), elongated, pale bluish-green with brown and blackish dots, blotches and scrawls, dimensions 24·6–25·3 × 16·2–16·3 mm; no information on incubation and nestling periods.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Rather uncommon to fairly common and locally common. Tolerates moderate habitat modification.
Bibliography. Fraga (2009), Greeney & Gelis (2008), Gyldenstolpe (1941b, 1945a), Hilty (2003), Jaramillo & Burke (1999), Maillard & Herrera (2007), Remsen *et al.* (1988), Restall *et al.* (2006), Ridgely & Tudor (1989), Schubart *et al.* (1965), Snyder (1966).



Genus *GYMNOMYSTAX* Reichenbach, 1850

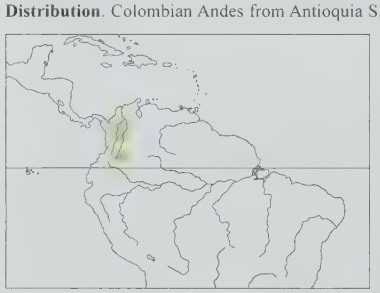
85. **Oriole Blackbird**

Gymnomystax mexicanus

French: Carouge loriot **German**: Nacktaugentrupial **Spanish**: Chango Oriolino

Taxonomy. *O.*[*riolus*] *mexicanus* Linnaeus, 1766, Mexico; error = French Guiana.
Molecular data indicate close relationship to *Hypopyrrhus* and *Lampropsar*, despite very different plumage. Monotypic.
Distribution. N, NE & WC Venezuela S through E Colombia (E of Andes) and an isolated spot in Cauca Valley; also NE Guyana and extreme N Brazil (Roraima); and Amazonia from E Ecuador, NE Peru (S to Ucayali) and extreme SE Colombia (Leticia, in extreme SE Amazonas) E along R Amazon (S to lower R Tapajós and lower R Tocantins) to Amapá, Marajó I and Mexiana I (Brazil), and French Guiana.

Descriptive notes. Male average 30·5 cm, 93·5 g; female average 27 cm, 92 g. Distinctive, large, bright icterid. Head and underparts are bright chrome-yellow, upperparts and tail black; upperwing black, lesser coverts and carpal area yellow (epaulets); bare circumorbital area, lores and malar streak black; iris brown; bill and legs black. Sexes similar. Juvenile is paler yellow than adult, has black cap, brownish tinge on upperparts, indistinct thin pale edgings on flight-feathers, bare facial area pinkish-grey; immature like adult, sometimes some back on rear crown. Voice. Most vocalizations are screechy, rasping and unmusical. Song, by both sexes, variable, usually consists of 4–6 harsh buzzing sounds; one song type transcribed as "chaa-chaa-chrick-chaa". A characteristic call is a harsh buzzy crescendo, "chsssswk", sounding like a burst of white noise; also harsh rattles.
Habitat. In Orinoco Basin (the *llanos*) found in savannas with scattered trees, tall grasslands and marshes, cattle pastures and agricultural stubble, usually not far from water. In Venezuela also in artificial habitats such as open city parks and large suburban lots (even in Caracas). In Amazonia frequents open riparian vegetation (early successional) on new islands and sandbanks, floating *várzea* grasslands of *Paspalum* and *Echinochloa*, and muddy river beaches; reputedly absent from floodplains of blackwater rivers. Roosts in swamps. Lowlands to 400 m, rarely to 950 m.
Food and Feeding. Almost omnivorous. Diet arthropods, including spiders (Araneae), crickets (Gryllidae) and caterpillars (Lepidoptera), also small vertebrates (e.g. frogs), also seeds, including those of cultivated maize (*Zea mays*), and fruits (*Cordia*). Forages mostly on ground and in low vegetation. Turns over objects such as cow dung and river debris to find hidden prey. Found in pairs and in flocks of up to 80 individuals; rarely joins mixed-species foraging flocks.
Breeding. Season May–Jun in Venezuela, Feb in SE Colombia and Mar in Peru. Probably monogamous. Solitary breeder. Nest built by both sexes, mostly by female, a thick-walled open cup, one was made from weeds and grass stems, lined with rootlets, external diameter 17 cm and depth 11 cm, internal diameter 8·5 cm and depth 5·5 cm, placed 6 m up in parasitic plant, possibly mistletoe (Loranthaceae), growing in chaparro tree (*Curatella americana*); another nest was composed mostly of rachises of a leguminous tree, built 7 m above ground in crown of isolated palm (*Attalea butyracea*) in a pasture. Clutch 3 eggs, pale blue with spots and irregular blotches in lilac, shades of brown and black, mean dimensions 28 × 20·4 mm; incubation period c. 17 days; chicks fed by both parents, no information on duration of nestling period. Nests parasitized by *Molothrus bonariensis*.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common in most of range. Rare in Guyana, from where few recent records; discovered only recently (1980s) in N Brazil (Roraima). Reported also in W Colombia (upper Cauca Valley), but status there uncertain. Tolerates, and expands with, moderate human disturbance. In Venezuela has spread into man-made environments in suburban and urban areas, including Caracas.
Bibliography. Barnett *et al.* (2002), Cherrie (1916), Cruz & Andrews (1989), Fraga (2009), Goeldi (1897), Hilty (2003), Jaramillo & Burke (1999), Remsen & Parker (1983), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schubart *et al.* (1965), da Silva (1998), Skutch (1967b), Thomas (1979).



Genus *HYPOPYRRHUS* Bonaparte, 1850

86. **Red-bellied Grackle**

Hypopyrrhus pyrohypogaster

French: Carouge à ventre rouge **German**: Rotbauchstärling **Spanish**: Chango Ventrirrojo

Taxonomy. *Cassicus pyrohypogaster* de Tarragon, 1847, Colombia.
Molecular-genetic data indicate that this species' closest relatives are *Gymnomystax* and *Lampropsar*, but that it has evolved in isolation for a long time (4 million years) and is highly distinctive. Monotypic.
Distribution. Colombian Andes from Antioquia S, discontinuously, to Putumayo.

Descriptive notes. Male average 31·5 cm, 101 g; female average 27 cm. Distinctive, robust blackbird. Plumage is glossy black, with vivid red belly and crissum; feather shafts of head and throat pointed and shiny black, giving streaked appearance; iris pale yellow; bill and legs black. Sexes similar, female smaller than male. Juvenile differs from adult in having black areas dull dark brown, red areas paler and more orange, thigh and rear flanks brown with reddish feather tips; immature like adult, but retained juvenile flight-feathers contrastingly brown. Voice. A rather musical "peero-peero", also trills and warbles. Song described as "glok-glok-schle-o", but considerable geographical variation. Contact call a harsh note; shrill "peep".
Habitat. Primary and secondary montane forests, forest edge, also pastures and plantations near forest patches. Reported at 800–2750 m, mostly above 1200 m.
Food and Feeding. Possibly omnivorous. Feeds on arillate fruits of *Cupania*, also berries of *Miconia* and figs (*Ficus*), and reported as feeding on seeds of *Chusquea* bamboos during rare

mast occurrences; arthropods taken include spiders (Araneae), orthopteroid insects and caterpillars (Lepidoptera). Nestling diet mostly insects. Forages mostly in canopy, in flocks of up to 30 individuals; sometimes with mixed-species foraging flocks of other mountain icterids, e.g. *Cacicus uropygialis*, also with Red-ruffed Fruitcrows (*Pyroderus scutatus*) and Green Jays (*Cyanocorax yncas*).

Breeding. Season Jan–May in C Andes, Mar–Aug elsewhere, but reported also Aug–Dec. Solitary nester. Co-operative breeder, in groups of 3–6 individuals, including adults of both sexes and juveniles; mutual feeding between group-members reported. Nest built by female, a bulky open cup made from sticks and large dry leaves, one with external diameter 17·3 cm and external depth 15 cm, placed in tree or shrub of native species (*Cupania*, *Tibouchina*, *Miconia*), sometimes in exotic species, e.g. cypress; one nest was 9 m above ground in isolated tree in pasture. Clutch 2–4 eggs, greenish-grey with dark brown and lilac spots; incubation by female, period 13–15 days; chicks fed by many group-members, including older juveniles, nestling period 14–18 days; fledglings remain in vicinity of nest for c. 5 days.

Movements. Resident; perhaps some local altitudinal movements.

Status and Conservation. ENDANGERED. Restricted-range species: present in Colombian Inter-Andean slopes EBA and Chocó EBA. Rare and local; fairly common in a few places. Although recently discovered at several new localities, total population small and fragmented. Recorded in W Andes from Cerro Tatamá (Valle del Cauca) and N into Antioquia, in C Andes from Antioquia (many historical sites and a few modern ones) S locally to Putumayo, and in E Andes in S Huila and W Caquetá. Since c. 1980, observed in small numbers very locally, but reported as quite common in mountains around Medellín and La Linda, Las Nubes and La Noque, in Antioquia; captive-bred individuals released around Medellín in 1997–1998. Found recently at several new localities, e.g. Amalfi, in Antioquia. Present known range includes some protected areas, such as Ucumarí Regional Park (Risaralda) and Cueva de los Guácharos National Park (Huila), where present in small numbers; in Antioquia, reported as common in La Forzosa Nature Reserve, Alto San Miguel Ecological Reserve, and La Romera and La Serrana Municipal Reserves; recent records also from Tatamá National Park (Risaralda–Chocó–Valle), Las Orquídeas National Park (Antioquia) and Cordillera de los Pichados National Park (Caquetá). Appears able to live at forest edges and in old second growth (and has nested in isolated tree in pasture), suggesting some tolerance of forest clearance and disturbance. Sometimes persecuted as a crop pest; sometimes captured for cagebird trade.

Genus *CURAEUS* P. L. Sclater, 1862

87. Austral Blackbird

Curaeus curaeus

French: Carouge austral **German**: Stachelkopfstärling **Spanish**: Tordo Patagón

Taxonomy. *Turdus Curaeus* Molina, 1782, Chile.

Similar in aspect and behaviour to *Gnorimopsar chopi*, but molecular data suggest closer relationship with quite different *Amblyramphus holosericeus*. Geographical variation partly clinal, body mass increases from N to S. Proposed race *recurvirostris* (described from Riesco I, in S Chile), resembling *reynoldsi* but supposedly with slightly recurved bill, requires further study, as recent observers have not reported peculiarities in bill shape. Two subspecies recognized.

Subspecies and Distribution.

C. c. curaeus (Molina, 1782) – C & S Chile from Coquimbo (rarely Atacama) S, including Chiloé I and most islands along coast, to Straits of Magellan, and SW Argentina (Neuquén S along Andes to Santa Cruz).

C. c. reynoldsi W. L. Sclater, 1939 – S Chile and extreme S Argentina (Tierra del Fuego and nearby islands).

Descriptive notes. Male average 26·8 cm and 83·3 g, female average 82·9 g (nominate, SW Argentina); male 114·6 g, female 99·1 g (*reynoldsi*). A large blackbird with long bill noticeably flattened on culmen ridge. Plumage is entirely black with slight bluish gloss, feathers of crown and nape somewhat lanceolated; iris dark brown; bill and legs black. Differs from superficially similar *Molothrus bonariensis* mainly in larger size, pointed bill shape, duller black colour. Sexes similar. Juvenile is duller and more brownish than adult. Race *reynoldsi* is larger and narrower-billed than nominate. VOICE. Song distinctive, a slow repetition of trills and hollow squeaky whistles mixed with "koo-ree-teeoo" call, phrases repeated slowly with clear pauses between them. A common call is a distinctive nasal, but not harsh, "koo-ree-teeoo" or "kooree-tee", often repeated. Much group calling and singing.

Habitat. Mesic Mediterranean-type scrub and woodland in C Chile, mostly in valley bottoms, also open evergreen or deciduous *Nothofagus* woodland, usually at edges or in clearings, farther S; also lakeshores and sea beaches, pastures, pine (*Pinus*) plantations and agricultural fields. In Argentina confined to *Nothofagus* forest and its surroundings, but even there seldom seen in continuous unbroken forest. In N half of Tierra del Fuego found in humid steppes. Sea-level to 1500 m.

Food and Feeding. Omnivorous, consuming insects, aquatic invertebrates, small vertebrates, seeds, fruits, some nectar (from the bromeliad *Puya*). Aquatic invertebrates taken include shrimps (Decapoda), small vertebrates include small rodents, and bird eggs and nestlings; feeds on seeds of cultivated cereals, e.g. maize (*Zea mays*) and wheat, and takes both wild fruits (such as *Aristotelia chilensis* and *Berberis*) and cultivated ones (cherries, grapes, apricots). Stomach contents included beetles (Coleoptera), moth caterpillars (Lepidoptera) and grass seeds. Picks chicken food in poultry yards, and household food scraps around houses and barns. Forages mostly on the ground, including on rocky seashores in S Chile. Probes into leaf litter; also finds prey items under pieces of bark and small stones lying on ground. Usually in groups of six to c. 20 individuals.

Breeding. Season Oct–Dec; three nests in Argentina (Victoria I, on L Nahuel Huapi) contained incubated eggs or recently hatched chicks in mid-Dec. Solitary nester, apparently monogamous. Some co-operative breeding. Nest a bulky cup of plant material e.g. twigs, grass stems, bamboo leaves, etc., mixed with some mud, lining of finer material, three nests from Victoria I had external diameter 20–25 cm and internal diameter 11 cm, internal depth 7 cm, placed 1·5–3 m above ground in dense vegetation in low tree or shrub, including native *Chusquea* bamboo and introduced plants e.g. European briar (*Rosa rubiginosa*), elmleaf blackberry (*Rubus ulmifolius*) or common broom (*Cytisus scoparius*). Clutch 3–6 eggs, pale bluish with few black spots and scrawls around large end, sometimes unmarked, mean dimensions 30·2 × 21 mm; no information on incubation and nestling periods, nor on roles of sexes (female has brood patch, presumably incubates); at least six individuals (three colour-ringed) observed to feed chicks at one nest on Victoria I; fledglings fed by several group-members. Not reported as host of *Molothrus bonariensis*, suggesting some effective anti-parasite defences.

Movements. Largely resident. Some movement apparent; nominate race recorded as accidental in S Mendoza (WC Argentina) and on Atlantic coast of Patagonia (Puerto Deseado).

Status and Conservation. Not globally threatened. Common and widespread in much of range; less common in Tierra del Fuego. Tolerates, and even benefits from, moderate transformations of natural landscape. Found in many protected areas, including Puyehue and Vincente Pérez Rosales National Parks (Chile) and Lanín, Nahuel Huapi, Los Alerces and Los Glaciares National Parks (S Argentina).

Bibliography. Christie (2009), Christie *et al.* (2004), Housse (1945), Humphrey *et al.* (1970), Imberti (2005, 2006), Jaramillo (2003), Jaramillo & Burke (1999), Johnson & Goodall (1967), Markham (1970, 1971), Orians, Orians & Orians (1977), Ridgely & Tudor (1989), Sosa (2008), Zapata (1967).

88. Forbes's Blackbird

Curaeus forbesi

French: Carouge de Forbes **German**: Forbesstärling **Spanish**: Chango de Forbes

Taxonomy. *Agelaius forbesi* P. L. Sclater, 1886, Macuca, Pernambuco, Brazil.

Taxonomic status of this species was for a long time uncertain; was sometimes considered a rare hybrid between *Gnorimopsar chopi* and *Chrysomus ruficapillus*. Placed in present genus because bill shape similar to that of *C. curaeus*, but no DNA data available. General behaviour and voice suggest possible relationship with *Macroagelaius*, *Lampropsar*, *Gymnomystax* and *Hypopyrrhus*. Monotypic.

Distribution. E Brazil: Pernambuco and Alagoas; and Minas Gerais.

Descriptive notes. 21–24 cm. Medium-sized, slim, all-dark icterid with long tail, short and rather rounded wing, and pointed bill with flat culmen. Plumage is entirely black, with brownish or dusky tinge on rump, lower back and belly; lanceolate feathers with glossy shafts on head, sometimes also on throat; iris black; bill and legs black. Differs from similar *Gnorimopsar chopi* mainly in smaller size, and slenderer bill with straight culmen and lacking groove on lower mandible. Sexes similar. Juvenile apparently undescribed. VOICE. Rather harsh song a double nasal buzz, with fundamental frequency c. 1·7 kHz. Flight call sounds like "perelet"; alarm call a rattle.

Habitat. In N of range frequents forest edges and nearby marshy pastures, as well as groves of introduced mango trees (*Mangifera indica*). In S (Minas Gerais), R Doce population occurs in a preserved tract of humid Atlantic Forest near a main river, and population at Cavernas do Peruaçu in deciduous forest growing in limestone area (with dry season lasting 6 months). Often reported from sugar-cane fields. Reported at up to 890 m.

Food and Feeding. Arthropods and fruits, but no detailed information. Chicks fed with insects. Forages in small flocks of up to c. 30 individuals; recent reports of flocks containing up to c. 700 individuals.

Breeding. Season Mar–Aug (Alagoas); two broods in a season. Co-operative breeder. During nest-building one individual arranged material brought by other 2–3 individuals; nest a thick cup of plant material (weed stems), sometimes mixed with mud and dung, external diameters 17 cm, height 12 cm, internal diameter 8 cm, depth 6 cm, placed 3–12 m above ground in tree, especially mango (38 of 46 nests), usually anchored to forked branch within thick foliage, sometimes in epiphytic bromeliad or liana. Egg-laying starts 4–10 days after nest completed, clutch 1–4 eggs, usually 3, pale blue to greenish-blue with few black spots and scrawls around large end, mean dimensions 26·3 × 18·6 mm; helpers at nest reported also during incubation stage, incubation period 12–14 days, usually 13 days; chicks fed by several adults, no information on duration of nestling period. Nests frequently parasitized by *Molothrus bonariensis*, e.g. 64% of nests in Alagoas, and most parasitized nests were abandoned; in subsequent studies, parasitism rates of up to 100% recorded.

Movements. Probably resident.

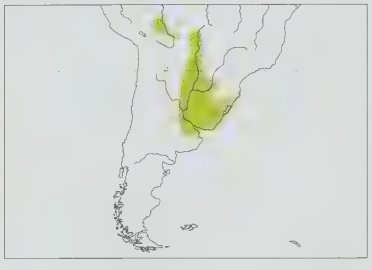
Status and Conservation. ENDANGERED. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Estimated global population 1000–2499 individuals; probably decreasing. Since initial discovery, in 1880 in Pernambuco and Alagoas, no further records for a century, probably chiefly because of confusion with far commoner *Gnorimopsar chopi*. In early 1980s rediscovered in Alagoas at Pedra Talhada, and in 1988 another population found, this more than 1400 km S, at Rio Doce, in Minas Gerais; in following year was found at other sites in Alagoas, with records from Usina Serra Grande, from near Matriz de Camaragibe, and from forest area known as Pedra Branca (near Murici), as well as from sugar-cane plantations and pastures bordering forest at Engenho Coimbra. More recently, has been recorded in Pernambuco at Usina Trapiche and at Mata do Estado (flocks of up to 709 individuals observed), and at São Vicente Ferrer and Engenho Água Azul, in Timbaúba, and reported as occurring at an additional nine localities in Pernambuco. Currently known from two sites in Minas Gerais, where up to 40 reported from confluence of Piracicaba and Doce rivers, and present on edge of Cavernas do Peruaçu National Park; other reports from Minas Gerais require confirmation. Seems to be naturally rare, but may be declining also owing to human alteration of its environment. Main threat appears to be parasitism by *Molothrus bonariensis*, which has increased in numbers; in addition, *Molothrus rufoaxillaris*, a specialist on icterids, has recently invaded E Brazil and may eventually parasitize this species. Experiments with removal of *Molothrus bonariensis* eggs found in the blackbird's nests are being conducted at Pedra Talhada. This blackbird is also captured for keeping as a pet and for cagebird trade. Occurs in several protected areas: at Pedra Talhada Biological Reserve (Alagoas) protection enforced by guards, but this species occurs mostly outside the reserve; at Rio Doce State Park (Minas Gerais) regularly recorded only in very small area between park entrance and L Carioca; at

Cavernas do Peruaçu National Park (Minas Gerais) seems to be present only at edge (in deciduous forest on limestone), but study in progress.

Bibliography. Anon. (2010d), Butchart & Stattersfield (2004), Jaramillo & Burke (1999), de Lyra-Neves *et al.* (2004), Ridgely & Tudor (1989), Short & Parkes (1979), Sick (1993), Stattersfield & Capper (2000), Studer (1982), Studer & Vielliard (1988), de Vasconcelos, D'Angelo Neto *et al.* (2006), Willis & Oniki (1991).

Genus *AMBLYRAMPHUS* Leach, 1814

89. **Scarlet-headed Blackbird**



Amblyramphus holosericeus

French: Carouge à tête rouge **German**: Rotkopfstärling **Spanish**: Federal
Other common names: Scarlet-headed Marshbird, Orange-headed Blackbird

Taxonomy. *Xanthornus* (*holosericeus*) Scopoli, 1786, Panay island, Philippines; error = the Paraná River Delta, Argentina.

Analysis of mitochondrial DNA suggests relationship with *Curaeus*, but the two genera differ morphologically and behaviourally. Monotypic.

Distribution. NE Bolivia (Beni and Santa Cruz), most of Paraguay, and S Brazil (S from S Mato Grosso and Santa Catarina, occasionally Paraná and possibly also São Paulo) S to NW & E Argentina (N Salta, Córdoba, and E Chaco S to Buenos Aires) and Uruguay.

Descriptive notes. Male average 25 cm, 86 g; female average 22·5 cm, 75 g. Distinctive red-and-black icterid with sharply pointed, chisel-shaped bill, which sometimes appears slightly upturned. Narrow loral stripe and eyelids black, otherwise entire head, neck, upper breast and thigh bright scarlet-red, remaining plumage black with slight gloss; iris, bill and legs black. Sexes alike. Juvenile is very different from adult, lacks red altogether, has entire plumage brownish-black, paler and washed yellowish on throat and breast; gradually acquires orange-red feathers on head, older immature like adult but duller, sometimes with brown feathers admixed in reddish areas. Voice. Song (in sexual display) variable, may include rattles or a nasal buzz. Characteristic contact call, by both sexes, a long, descending and hesitant whistle, "fee-ee-ee", with some up-and-down pitch variations; has slight metallic quality and can be heard at considerable distances.

Habitat. Tropical to warm-temperate marshes with abundant, tall herbaceous vegetation, particularly with species of sedge (*Cyperus*), *Thalia* and cat-tail (*Typha*); sometimes visits grasslands or agricultural fields near marshes. Lowlands, usually below 600 m.

Food and Feeding. Diet mostly insects, and reported also as eating small frogs; may feed on cultivated maize (*Zea mays*) or sorghum seeds in non-breeding season. Specialized forager, extracts insect larvae (and adults) from stems of marsh plants, using its chisel-shaped bill as a probe and gaping to open stems. Generally found as scattered territorial pairs, but during non-breeding season flocks of up to 100 individuals observed.

Breeding. Season Oct–Dec in C Argentina, extending to Feb/Mar in N Argentina. Solitary nester. Apparently monogamous and strongly territorial. Reported territory sizes exceed 40 ha in Buenos Aires (Argentina). Nest built mostly by female, with some help from male, a sturdy cup-shaped structure built mostly from interlaced strips of *Typha* leaves, lined with finer strips of same material, most with internal diameter 8 cm and depth 7 cm, attached c. 1 m above water to 4–7 plant stems in marsh, favoured plants including duraznillo (*Solanum malacoxylon*), cat-tail and species of *Cyperus*; statement that this icterid builds a covered nest was based on an error. Clutch 3–4 eggs, pale greenish-blue with small spots and blotches in dark brown, mean dimensions 26·2 × 19 mm; incubation by female, male guards nest during this stage, period 13–14 days; chicks fed by both sexes, nestling period 13 days. Nests parasitized by *Molothrus bonariensis*, but aggressive nest-guarding seems to lower incidence of parasitism. Female may breed in juvenile plumage.

Movements. Apparently resident in permanent wetlands, such as Esteros del Iberá, in Corrientes (Argentina). Some movements evident in areas with strong dry season, e.g. most of the Chaco; seasonal movements seem to involve many immatures. Irregular movements also occur; abandons favoured localities during severe droughts, as at Paraná Delta (Argentina) in autumn 1997 (during a La Niña episode).

Status and Conservation. Not globally threatened. Categorized as "vulnerable" in Argentina. Uncommon to locally fairly common. As breeding territories large, this icterid does not occur at high densities. In Argentina, large-scale forestation of lower Paraná Delta with willows (*Salix*) and poplars (*Populus*) has removed or altered natural habitats; recent intensification of cattle-rearing on R Paraná islands, where natural vegetation now subject to extensive fires, probably has a negative effect on this icterid's populations. Drainage of marshes has so far not occurred on a large scale. Sometimes captured for the pet trade, although it cannot survive for long in captivity. Still found in several protected areas, including Beni Biosphere Reserve (Bolivia), San Rafael National Park (Paraguay), Pantanal Mato-grossense National Park (Brazil), Otamendi Reserve, Iberá Natural Reserve and Río Pilcomayo National Park (Argentina), and Bañados del Este Biosphere Reserve (Uruguay).

Bibliography. Azpiroz (1997), Belton (1985), Bornschein & Reinert (2000), Camperi (1990), Di Giacomo (2005), Fernández & Mermoz (2000), Fernández *et al.* (2007), Fraga (2001, 2007), Hartert & Venturi (1909), Jaramillo & Burke (1999), Kaiser (2006), Narosky & Di Giacomo (1993), Nores *et al.* (1991), Orians (1980), de la Peña (1987), Pereyra (1934), Ridgely & Tudor (1989), Schubart *et al.* (1965).

Genus *GNORIMOPSAR* Richmond, 1908

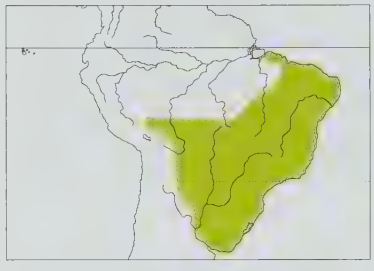
90. **Chopi Blackbird**

Gnorimopsar chopi

French: Carouge chopi **German**: Chopistärling **Spanish**: Chopí

Taxonomy. *Agelaius chopi* Vieillot, 1819, Paraguay.

Molecular data suggest an isolated position for this species, but in external morphology it seems closer to *Oreopsar bolivianus* and *Curaeus curaeus*; in nesting behaviour and voice it resembles *Agelaioides badius*. Race *megistus* sometimes subsumed in *sulcirostris*. Latter apparently intergrades with nominate in E Brazil (N Minas Gerais, possibly also Goiás). Three subspecies recognized.



Subspecies and Distribution.

G. c. sulcirostris (Spix, 1824) – NE Brazil E from Maranhão and Ceará and S to Bahia and N Minas Gerais (possibly also N Goiás).

G. c. chopi (Vieillot, 1819) – C & E Brazil (C Mato Grosso E to Goiás, Minas Gerais and Espírito Santo) S to NE Argentina (S to Santa Fe and Entre Ríos) and Uruguay.

G. c. megistus (Leverkühn, 1889) – extreme SE Peru (Pampas de Heath and Madre de Dios) E to E Bolivia (La Paz, Beni and Santa Cruz).

Reported also from S Bolivia (Tarija) and extreme N Argentina (extreme N Salta), but racial assignation of these populations doubtful; they may represent feral populations originated from escaped cagebirds.

Descriptive notes. Male average 23 cm, 73·9 g (nominate), 90·3 g (*sulcirostris*); female 69·7 g. Medium-sized all-dark icterid with groove along base of lower mandible (sulcate bill). Plumage is black overall, with little gloss except on head; head with distinctive shaggy lanceolate feathers with glossy black shafts; iris black, bill and legs black. Sexes alike. Juvenile is duller and more brownish than adult, and often lacks lanceolate head feathers. Readily distinguished from superficially similar *Molothrus bonariensis* and *Molothrus rufoaxillaris* by larger size, bill shape and relative lack of gloss. Race *sulcirostris* is larger and glossier than nominate, with bill more markedly sulcate; *megistus* is very like previous, but smaller. Voice. Song, by both sexes (often in group), variable, musical and complex, mostly a series of loud whistles with rich harmonics, the phrases mixed with trills, rattles and *sotto voce* sounds; some songs appear to include mimicry of other bird species (captives are good mimics); songs of *sulcirostris* (and *megistus*) reputedly more variable and musical, but main difference is lower pitch. Common call a loud "choo-peeh", often included in the song.

Habitat. Large clearings and edges in mesic to humid forest, including Brazilian Atlantic Forest, humid *chaco* and dry Chiquitano Forest and woodland; also open woodland and savanna (*cerrado*, mesic *chaco*). Frequent in palm groves (*Copernicia alba*, *Acrocomia aculeata*, *Butia yatay*). Occurs also in plantations, agricultural and pastoral land, small villages and even suburbs (e.g. in Santa Cruz, in Bolivia); recently reported in suburban La Paz and Cochabamba (Bolivia). Lowlands, nominate race to 1400 m in Brazil; *megistus* mostly in lowlands below 1200 m, but in Bolivia recently reported (probably introduced) at 2000–3400 m in Cochabamba and La Paz.

Food and Feeding. Mostly arthropods and small vertebrates, also seeds, and some fruit and nectar. Vertebrates eaten include a small frog and a recently dead juvenile Yellow-billed Cardinal (*Paroaria capitata*); takes both wild and cultivated seeds, latter including e.g. maize (*Zea mays*) and sorghum; fruits (unidentified) reported in stomach contents; rarely, feeds on flower nectar of native trees (e.g. *Erythrina dominguezii* in Chaco) and of introduced species (e.g. *Grevillea robusta*). Forages mostly on ground. Usually found in groups, and flocks of up to 100 individuals reported in non-breeding season; has well-developed sentinel behaviour. Roosts gregariously, often in bamboo, sometimes with other icterids.

Breeding. Season Oct–Jan in Paraguay, C & SE Brazil and Argentina; juveniles in Mar in E Bolivia. Breeds solitarily or in small colonies of up to seven or so pairs. Co-operative breeder. Nest built by both sexes, a loose or a well-made cup of diverse plant material, also string and scraps of paper, its size and shape fitting chosen cavity; placed inside hole or crevice in tree, in crown of palm (*Butia yatay*, *Copernicia*, *Acrocomia*), in closed nest built by other bird, particularly furnariid such as Rufous Hornero (*Furnarius rufus*) or *Phacellodomus* thornbird, or in crevice or hole in building or other artificial structure (e.g. powerline pole); accepts nestboxes. Clutch 3–5 eggs, bluish-green, sparsely scrawled and spotted in dark brown and blackish, mean dimensions (nominate race) 26·4 × 19·4 mm; incubation by female, period 14–15 days; both parents and helpers feed and defend chicks, nestling period 16–18 days. Nests commonly parasitized by *Molothrus rufoaxillaris* in NE Argentina, Paraguay and Brazil (possibly also in Uruguay and Bolivia), e.g. of 250 nests of present species monitored in study in NE Argentina 46% were parasitized; reported as host also of *Molothrus bonariensis* (based on a parasitized set of eggs in Delaware Museum of Natural History, in USA).

Movements. Resident.

Status and Conservation. Not globally threatened. Relatively common to locally common over most of its range. Quite adapted for living in moderately modified environments. Widely captured and traded as a cagebird for its song, it has become scarce in densely settled rural areas such as Entre Ríos, in Argentina, and also Uruguay; bird-trappers often destroy nest cavities in order to obtain chicks. Found in many protected areas throughout its range.

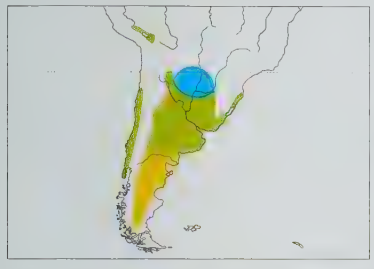
Bibliography. Azara (1802–1805), Azpiroz (1997), Belton (1985), Coconier *et al.* (2007), Di Giacomo (2005), Fraga (1996, 2006, 2008c), Graham *et al.* (1980), Hayes & Areco de Medina (1988), Hellmayr (1937), Hoy *et al.* (1963), Jaramillo & Burke (1999), de la Peña (1983, 1987), Pinto (1944a), Pizo (2008), Ridgely & Tudor (1989), Sick (1993).

PLATE 80 ➤

PLATE 80

inches 3

cm 8



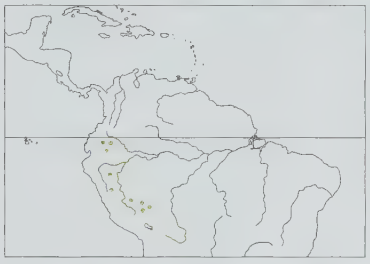
Genus *AGELASTICUS* Cabanis, 1851

91. Yellow-winged Blackbird

Agelasticus thilius

French: Carouge galonné **German**: Goldschulterstärling **Spanish**: Varillero Aliamarillo
Other common names: Yellow-shouldered Blackbird(!)

Taxonomy. *Turdus Thilius* Molina, 1782, Chile.
Genus often subsumed in *Agelaius* or *Chrysomus*. Analysis of mitochondrial DNA indicates that relationship of present species to two congeners (*A. xanthophthalmus* and *A. cyanopus*) is not close. Individuals somewhat intermediate between nominate race and *petersii* occur S of 42° S in Patagonia (Chile and Argentina). Three subspecies recognized.
Subspecies and Distribution.
A. t. alticola (Todd, 1932) – SE Peru (Cuzco, Puno) and W Bolivia (La Paz, Cochabamba and Oruro).
A. t. thilius (Molina, 1782) – Chile (Atacama S to Magallanes).
A. t. petersii (Laubmann, 1934) – breeds Argentina (from at least Santiago del Estero, Santa Fe and Corrientes S to Santa Cruz), Uruguay and SE Brazil (mostly along coastal marshes of Paraná, Santa Catarina and Rio Grande do Sul); in austral winter extends to extreme NE Argentina (Salta, Chaco, Formosa) and most of Paraguay, with few records in Bolivia (Izozog).



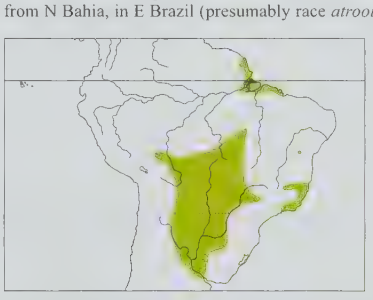
Descriptive notes. Male average 17·9 cm and 33·5 g; female 28·8 g (*petersii*). Male nominate race is entirely dull black, except for yellow marginal and lesser upperwing-coverts (epaulet), and similar pattern on underwing-coverts; iris brown; bill and legs black. Female has prominent pale buff supercilium, contrasting with dark brown, streaked crown and ear-coverts; rest of head and upperparts brown with broad dusky streaking, the brown edges becoming chestnut on lower scapulars and lower back; wing feathers dark brown with paler edges, more chestnut on inner greater coverts, hint of yellow on marginal coverts (but lacks male's epaulet); tail blackish, feathers thinly edged chestnut; light buff-brown below with darker streaking, chin and upper throat unstreaked, often a darker malar stripe; bare parts as for male. Juvenile is like female, but more buffish overall. Races differ mainly in size: *petersii* is smaller than nominate; *alticola* is larger than nominate, also female darker, more streaked, with thinner greyish supercilium (sometimes lacking), and usually with more yellow on marginal upperwing-coverts (sometimes approaching epaulet of male). Voice. Male song (nominate race and *petersii*) quite variable, but includes trills of 3–7 notes (resembling *A. cyanopus*), a whistled warble "tréé-o-lay" (or "séé-you-there"), and a similar warble ending with strong nasal or buzzing tone ("tree-o-lâáây"). Song of *alticola* less nasal. Sharp "chep" call given by both sexes.
Habitat. Patches of emergent aquatic plants, including cat-tails (*Typha*), bulrush (*Schoenoplectus*) and reeds (*Phragmites*), in marshes and wetlands, also surrounding grasslands and agricultural land; tolerates slightly brackish marshes. Roosts in marsh vegetation. May be found in treeless areas. Race *alticola*, the icterid that breeds at highest elevation, occurs mostly in wetlands in L Titicaca basin (Peru–Bolivia). Reported up to 2300 m (*petersii*); 2500–3800 m, rarely up to 4000 m (*alticola*).
Food and Feeding. Insects, including emerging aquatic insects, and seeds. Stomach contents of 85 adults from Buenos Aires province (Argentina) comprised 78% animal food and 22% seeds: animal food was mostly insects (66% of all food items) and included beetles (Coleoptera) of eleven families, mostly weevils (Curculionidae), other insect orders being Lepidoptera (mostly caterpillars and pupae), bugs (Hemiptera) and flies (Diptera); other invertebrates included wolf spiders (Lycosidae), crustaceans (Isopoda, Amphipoda) and molluscs; ingested seeds were mostly of native grasses (Poaceae) and sedges (Cyperaceae), also of families Papaveraceae and Caryophyllaceae. Seeks food items along edge of water and in shallow marshes or on nearby drier land; probes and gapes in stems. Forages in flocks.
Breeding. Season Oct–Dec in Chile and Argentina. Apparently monogamous. Colonial breeder, colonies usually in emergent marsh vegetation, less often in low dense vegetation in uplands but near a marsh; degree of nest-clumping variable, can reach five nests in radius of 5 m. Nest built by female, a well-made cup of plant material, usually pieces of wet rushes, cat-tails or other marsh plants, external diameter 8·5–9·5 cm, external height 7–7·5 cm, usually no more than 1 m above water or ground, mostly in bed of *Schoenoplectus californicus*, sometimes in cat-tails or *Phragmites* reeds, once in a patch of *Philostachys* bamboo near a marsh; if built in reeds, it is attached to several stems. Clutch 2–4 eggs, pale buffish-white with brownish-black spots and lines, mostly at large end, mean dimensions 23·4 × 17 mm; incubation by female, period 12–13 days; chicks fed by both sexes, female's feeding rate the higher in one study, male also guards nest and/or escorts breeding female, nestling period 10–12 days. Nests commonly parasitized by *Molothrus bonariensis*; successfully rears latter's chicks.
Movements. Resident in Uruguay and Brazil. Possibly some altitudinal movement in Peru–Bolivia (race *alticola*). S Argentinian populations of *petersii* (S from S Mendoza) migrate N during austral winter. In extreme NE Argentina and Paraguay mostly, or only, a non-breeding winter visitor; N limits of breeding range in Argentina not well known, but extend at least to Santiago del Estero, Santa Fe and (perhaps) S Corrientes.
Status and Conservation. Not globally threatened. Rather common over most of its range, becoming naturally rarer or local towards subtropics. Scarce but widespread non-breeding visitor in Paraguay. Occurs in several protected areas, including, among others, Laguna Alalay (Bolivia), Vicente Pérez Rosales and Puyehue National Parks (Chile), Nahuel Huapi and Lanín National Parks, Laguna Llancanelo Reserve and Laguna de Mar Chiquita Natural Park (Argentina), Taim Ecological Station (Brazil) and Bañados del Este Biosphere Reserve (Uruguay).
Bibliography. Azpiroz (1997), Belton (1985), Bornschein *et al.* (1997), Camperi (1988), Christie *et al.* (2004), Darrieu *et al.* (2001), Fraga (2002), Guerrero & Arambiza (2001), Hayes *et al.* (1994), Imberti (2003), Jaramillo & Burke (1999), Massoni & Reboreda (2001, 2005), Narosky & Di Giacomo (1993), Nores & Yzurieta (1980), Orians (1980).

92. Pale-eyed Blackbird

Agelasticus xanthophthalmus

French: Carouge à oeil clair **German**: Gelbaugenstärling **Spanish**: Varillero Ojipálido
Other common names: Yellow-eyed Blackbird

Taxonomy. *Agelaius xanthophthalmus* Short, 1969, Tingo Maria, Huánuco, Peru.
Genus often subsumed in *Agelaius* or *Chrysomus*. Present species closely related to *A. cyanopus*. Monotypic.
Distribution. Lowlands of Amazonian Ecuador (Napo) and Peru (San Martín, Huánuco and Madre de Dios).



Descriptive notes. Male average 20·5 cm, 43 g; female 18·2 cm. A slender-billed all-dark icterid with pale eyes. Male is entirely black with slight bluish-green gloss, also ultraviolet reflection in crown and supercilium (not reported for related species); iris pale yellow; bill and legs black. Female is very like male, but smaller, somewhat less glossy, also possibly lacking ultraviolet reflection. Juvenile is brown, back feathers and tertials with thin buffy tips, yellowish-buff streaking below, particularly on throat and upper breast, iris dark. Voice. Song, by both sexes, variable series of repeated notes, e.g. "chee-cheee-chee..." or "tew-tew-tew...", also a slow trill; duets reported. Contact call "chek".
Habitat. Wetlands, particularly edges of oxbow lakes, with abundant emergent and floating vegetation; seems to prefer areas dominated by the aquatic grass *Panicum grande*. Up to 650 m.
Food and Feeding. Main food insects; presumably other arthropods, and seeds, also taken. Obtains prey by gaping in the sheathing bases of grass leaves and in clusters of dead leaves; also by gleaning in aquatic vegetation. Reported as catching alate termites (Isoptera) in flight. Moves in pairs and in family groups.
Breeding. Season Nov in Peru. Scant data indicate monogamy and solitary breeding. One nest described, built from plant materials like strips of the grass *Panicum grande*, also leaf strips of *Heliconia metallica*, the vine *Mikania* and the palm *Scheelea cephalotes*, unlined cup 7 cm in diameter, anchored 45 cm above water in aquatic plant *Ludwigia leptocarpa* within clump of *Panicum grande*. Clutch 2 eggs, pale bluish-white with scattered brown blotches, more heavily marked around large end. No further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Scarce to rare, and very local. Known from very few localities. Because of its restricted range and relatively small populations, it might require listing as Near-threatened (particularly in Ecuador). Protected in Manu National Park and Biosphere Reserve (Peru).
Bibliography. Eaton (2006), Jaramillo & Burke (1999), Kiltie & Fitzpatrick (1984), Orians & Orians (2000), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schulenberg *et al.* (2010).

93. Unicolored Blackbird

Agelasticus cyanopus

French: Carouge unicolore **German**: Einfarbstärling **Spanish**: Varillero Negro

Taxonomy. *Agelaius cyanopus* Vieillot, 1819, Paraguay.
Genus often subsumed in *Agelaius* or *Chrysomus*. Present species is closely related to *A. xanthophthalmus*. Four subspecies recognized.
Subspecies and Distribution.
A. c. xenicus (Parkes, 1966) – NE Brazil (Amapá, NE Pará and N Maranhão); possibly also French Guiana.
A. c. beniensis (Parkes, 1966) – N Bolivia (Beni).
A. c. cyanopus (Vieillot, 1819) – E Bolivia (Santa Cruz) and C & S Brazil (S from Mato Grosso and W São Paulo) S across Paraguay to NE Argentina (S to NE Buenos Aires) and W Uruguay.
A. c. atroolivaceus (Wied, 1831) – coastal plain of E Brazil from Espírito Santo S to Paraná.
A few individuals reported from SW Amazonian Peru may belong to race *beniensis*; reported also from N Bahia, in E Brazil (presumably race *atroolivaceus*).

Descriptive notes. c. 18–21 cm; male average 40·6 g, female 37·4 g. A slender-billed, long-tailed icterid. Male nominate race is entirely black with very slight bluish gloss; iris dark brown; bill and legs black. Female has crown and upperparts brown, boldly streaked blackish, with narrow yellowish supercilium (often ill-defined) and blackish ear-coverts; upperwing brownish, most feathers with conspicuous rufous edging, tail blackish; pale yellow below, streaked dusky brown on flanks, sometimes streaked also on breast, underwing-coverts pale yellow; lower mandible sometimes with bluish-grey to pale horn at base or along entire length. Juvenile resembles female, but more buffy yellow, also more heavily streaked above and below; many males do not acquire adult plumage until second year. Races differ mainly in coloration of female: *atroolivaceus* female is much darker overall than nominate, underparts dark brownish-olive with yellowish wash, palest on throat; *beniensis* is larger than others, female has darker upperparts and underwing-coverts, but underparts somewhat intermediate in tone between previous and nominate; *xenicus* female is distinctive in having entire head to mantle and breast blackish

On following pages: 94. Yellow-hooded Blackbird (*Chrysomus icterocephalus*); 95. Chestnut-capped Blackbird (*Chrysomus ruficapillus*); 96. Saffron-cowled Blackbird (*Xanthopsar flavus*); 97. Yellow-rumped Marshbird (*Pseudoleistes guirahuro*); 98. Brown-and-yellow Marshbird (*Pseudoleistes virescens*); 99. Greyish Baywing (*Agelaioides badius*); 100. Pale Baywing (*Agelaioides fringillarius*).

with olivaceous wash, and dull, dark olive-yellow belly. Voice. Song, apparently by both sexes, alternating liquid "shr-r-le" rattles with series of repeated warbles or trills ("wie-wie-wie-wie", "chie-chie-chee", etc.), somewhat resembling sound of distant car alarm. In courtship also a short buzzing "kt-zéé". Contact call "chieg".
Habitat. Permanent marshes with abundant emergent vegetation, such as sedge (*Cyperus*), *Thalia* and cat-tail (*Typha*), and floating vegetation, such as water-cabbage (*Pistia*), duckweed (*Lemna*) and water-fern (*Azolla*); often the most frequent icterid in extensive wetlands of this type (e.g. Iberá marshes, in Argentina). Also visits surrounding grassland and agricultural fields. Can be found in low riparian vegetation along slow rivers and channels. Sometimes perches on trees. Lowlands; nominate race up to 500 m.
Food and Feeding. Arthropods (mostly insects), small vertebrates and seeds; reported as taking nectar from inflorescences of the vine *Combretum lanceolatum*. Seeds constituted c. 50% of stomach contents; seeds ingested were of aquatic grasses (*Paspalum repens*, *Echinocloa polystacha*) and of Polygonaceae. Feeds on maize (*Zea mays*) and other seed crops, mostly in non-breeding season. Main insect prey in stomach contents were beetles (of families Curculionidae and Dytiscidae) and dipteran flies (of families Chironomidae and Stratiomyidae); vertebrates ingested were mostly small cichlid fishes (*Apistogramma commbrae*) up to 3 cm long. More aquatic than other marsh blackbirds, commonly searching for food while perched on floating vegetation. Picks prey from underside of floating plants (*Pistia*, *Azolla*, etc.) and from water's surface. Forages also on the ground, showing "rolling" behaviour. Often in small groups of fewer than ten individuals, but flocks of c. 100 birds seen in non-breeding season; sometimes joins other icterids, and in marshes may associate with Donacobius (*Donacobius atricapilla*).
Breeding. Season Oct–May (mainly Nov–Feb) in NE Argentina; more than one brood attempted per season. Breeds solitarily or in small colonies of up to 20–30 nests in marshes or flooded grasslands. Nest-building takes 5–10 days, nest cup-shaped and made from interlaced wet plant material (cat-tail and grass leaves) that dries to a cardboard-like consistency, external diameter 8–9 cm, external depth 9–10 cm, built 0·7–1·7 m over water mostly in emergent aquatic plants, e.g. cat-tails (*Typha domingensis*), "piri" (*Cyperus giganteus*) or *Thalia geniculata*, or in the grass *Panicum prionites* or in aquatic shrub *Solanum malacoxylum* or *Ipomea malvaeoides*. Clutch 3 eggs, pale greenish-blue with grey and brownish spots, also blackish lines, mostly around large end, mean dimensions 23·2 × 16·8 mm; incubation by female, period 12 days; chicks fed by both parents, nestling period 11 days; three broods of well-feathered fledglings in Iberá marshes (Argentina) fed only by female, roles of sexes in parental care require more study. Nests parasitized by *Molothrus bonariensis*.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Locally numerous; rare and local in Rio Grande do Sul (S Brazil) and Uruguay. Appears to be locally abundant particularly in Bajo Chaco (Paraguay), the Iberá marshes (Argentina), parts of the Pantanal (S Brazil and nearby areas) and the Beni savannas (Bolivia). Occurs in several protected areas, including Beni Biosphere Reserve (Bolivia), Pantanal Mato-grossense National Park (Brazil), Isla Yacyretá Reserve (S Paraguay), and Predelta and Chaco National Parks and Iberá Natural Reserve (Argentina).

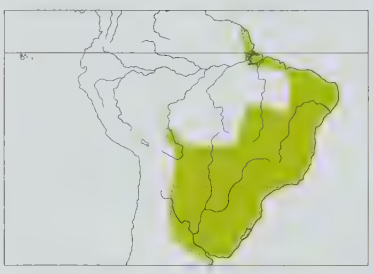
Genus *CHRYSOMUS* Swainson, 1837

94. Yellow-hooded Blackbird

Chrysomus icterocephalus

French: Carouge à capuchon **German**: Gelbkopfstärling **Spanish**: Varillero Capuchino

Taxonomy. *O.[riolus] icterocephalus* Linnaeus, 1766, Cayenne, French Guiana.
Genus often subsumed in *Agelaius*. Behavioural and molecular data indicate that this species is closely related to *C. ruficapillus*. Two subspecies recognized.
Subspecies and Distribution.
C. i. icterocephalus (Linnaeus, 1766) – N Colombia (S to N Tolima, Meta and Vichada), Venezuela (mostly N of R Orinoco), Trinidad, the Guianas, N Brazil (Roraima; both banks of R Amazon E to Amapá and NW Maranhão) and NE Peru (Loreto).
C. i. bogotensis (Chapman, 1914) – NC Colombia (highlands around Bogotá).



Descriptive notes. c. 17–19 cm; male average 35·9 g, female average 26·8 g. Male nominate race has head to throat and upper breast bright yellow, lores black; rest of plumage glossy black; iris dark brown; bill and legs black. Female has supercilium and throat to uppermost breast yellow, rest of face and crown citrine; upperparts dull greyish-olive with dusky streaking, wing and tail darker, more brownish-olive; underparts olive, more brownish on belly, faintly streaked olive; bill blackish, often paler at base of lower mandible. Juvenile is like female, but duller, with less yellow on head, paler upperparts, buffish underparts obscurely streaked; immature male like female, but brighter and more extensive yellow on throat, and may show black feathers in underparts and upperparts. Race *bogotensis* is larger than nominate, female darker, with head less yellowish, dusky olive or blackish mask over lores to ear-coverts strongly contrasting with long, narrow superciliary skirting ear-coverts and meeting a rather well-defined yellow bib. Voice. Male has two song types, one consisting of brief notes or whistles followed by harsh buzz, the other a more variable and pleasant sequence of warbles or whistles; the two types may be alternated; song structures similar to those of male *C. ruficapillus*, but tone harsher and less musical. Group singing frequent. Call "chek", also a descending whistle.
Habitat. Marshes (permanent or seasonal) with emergent aquatic plants such as cat-tails (*Typha*), bulrushes (*Schoenoplectus*), *Thalia* and similar; along R Amazon and main tributaries found mostly in *várzea* grasslands with grasses *Paspalum* and *Echinochloa*. Also humid savannas and mangroves, and agricultural land; particularly active in abandoned rice fields. Forages in ploughed fields. Lowlands to 1000 m (nominate race); race *bogotensis* to 2600 m.
Food and Feeding. Diet seeds and insects. Among seeds cultivated rice important; feeds also on wild rice (*Oryza perennis*). Insects in stomach contents included caterpillars (Lepidoptera) and weevils (Curculionidae). Nestling diet mostly insects, especially katydids (Tettigoniidae) and other Orthoptera. Forages mostly in grass and vegetation; occasionally on ground. Brood-feeding females of nominate race commonly obtain food outside male's territory, but *bogotensis* females locate food items within it. Found in small groups; in non-breeding season often in larger flocks, sometimes of several hundred individuals.
Breeding. Season mainly Jul–Oct in Venezuela (Oct–Nov in *llanos*), May–Nov in Trinidad, and Mar–Sept in Suriname; Mar–May in C Colombia (race *bogotensis*); breeding highly synchronized in seasonal Venezuelan *llanos* and other localities with clear-cut rainy season. Harem or successive polygyny the usual mating systems, harems small (mostly 2–5 females); solitary nesters and some colonial ones monogamous. Mostly colonial, in colonies of variable size (up to 100 nests reported) in or near marshes, or in rice fields; some nests solitary, or scattered in semi-colonies. Male territory 15–50 m in diameter (Trinidad, Suriname), smaller, 4–8 m in diameter, in *llanos*; average 308 m² in C Colombia (race *bogotensis*). Nest built by male, cup-shaped, made from wet plant material that dries up, external diameter 10·1 cm and external depth 9·1 cm (nominate race), or respectively 11·2 cm and 10·4 cm (*bogotensis*), tied to several stems usually 0·5–1 m above water in emergent aquatic vegetation (*Thalia*, *Eleocharis*, *Cyperus*, *Leersia*), rarely in tree or shrub near water; if female accepts nest, she lines it, male then remains with her until second day of incubation; many nests remain unused (in *llanos*, c. 33% of territorial males do not obtain a female). Clutch 2–4 eggs, pale blue to white with sparse blackish spots and lines around large end, mean dimensions 22 × 16·3 mm (Trinidad); incubation by female, in *llanos* starting with first egg (hatching asynchronous), period 11–13 days; chicks fed by female, some male participation, nestling period 11–12 days; male defends nest against predators and parasitic *Molothrus bonariensis*. About 30–40% of nests parasitized by *Molothrus bonariensis*; female seldom removes latter's eggs, but deserts if three or more parasite eggs (in *llanos* only 14% of parasitized nests produced cowbird chicks). Nesting success quite variable from one year to another in *llanos* population, depending on rainfall.
Movements. Largely resident. Local movements reported from areas with strongly marked dry season, such as Venezuelan *llanos*. Nominate race recorded as accidental in Netherlands Antilles.
Status and Conservation. Not globally threatened. Fairly common to locally common. Race *bogotensis*, with very small range, may merit local protection.
Bibliography. Belcher & Smooker (1937), Cadena *et al.* (2011), Cruz & Andrews (1989), Cruz *et al.* (1990), ffrench (1991), Haverschmidt (1968), Hilty (2003), Jaramillo & Burke (1999), Lowther *et al.* (2004), Manolis (1982), Naranjo (1995), Restall *et al.* (2006), Ridgely & Tudor (1989), Wiley & Wiley (1980a, 1980b).

95. Chestnut-capped Blackbird

Chrysomus ruficapillus

French: Carouge à calotte rousse **German**: Braunkopfstärling **Spanish**: Varillero Congo
Other common names: Rufous-headed Blackbird

Taxonomy. *Agelaius ruficapillus* Vieillot, 1819, Paraguay.
Genus often subsumed in *Agelaius*. Behavioural and molecular data indicate that this species is closely related to *C. icterocephalus*. Races probably once separated, but now appear to meet and possibly intergrade in SE Brazil (São Paulo). Two subspecies recognized.
Subspecies and Distribution.
C. r. frontalis (Vieillot, 1819) – coast of French Guiana, and E Brazil (Amapá, including Marajó I, E to Rio Grande do Norte, then S to Goiás, Minas Gerais and São Paulo).
C. r. ruficapillus (Vieillot, 1819) – E Bolivia (Santa Cruz) and S Brazil (Mato Grosso do Sul E to São Paulo and Rio Grande do Sul) S to NE Argentina (NE La Pampa and Buenos Aires) and Uruguay.

Descriptive notes. Males average 18·5 cm, 41·3 g; female average 17·1 cm, 32·2 g. Male nominate race has most of crown, throat and uppermost breast deep dark chestnut (looking black in poor light or at distance), rest of plumage black with slight bluish gloss; iris dark brown; bill and legs black. Female has indistinct buffish supercilium, is olivaceous brown above, faintly streaked with dusky; throat and upper chest pale buff to tawny, underparts dull olivaceous buff, all with faint dark streaking. Juvenile is similar to female, but paler, more buff-brown, with upperwing-coverts edged warmer brown, underparts more heavily streaked. Race *frontalis* male has crown and throat ferruginous, paler than nominate, and with narrow black band around base of bill, female has yellowish tinge on head and more visibly on throat. Voice. Males have two song types, sometimes produced in alternate sequences: one type starts with clicks, warbles or whistles and ends in descending nasal buzz, whereas the other can be quite musical, either a series of loud, short and tremulous whistles around a sustained pitch (like a flute playing coloratura) or flute-like notes on ascending scale (Brazilian name "do-re-mi"); much variation among males, even within single colony. Songs of N race *frontalis* similar to those of nominate, but harsher in tone. Much group singing performed by both races. Soft contact call "zeb"; also a "peet" call.
Habitat. Marshes (permanent or temporary), rice fields, wet grasslands and agricultural fields; invades recently flooded areas. May appear in open woodlands near wetlands, sometimes nesting and roosting in trees. N race *frontalis* commonly seen in irrigated fields, and around barnyards and corrals in the *caatinga*.
Food and Feeding. Seeds, insects and spiders (Araneae). Feeds heavily on cultivated rice seeds (12–62% of stomach contents); in natural conditions feeds mostly on grass seeds (especially *Sorghastrum*, *Paspalum* and *Echinocloa*). Forages on emergent vegetation in marshes, but also on ground in dry soil. Gregarious, almost invariably in flocks of up to 1000 individuals, sometimes several thousands; in Argentina males may segregate in separate flocks during Mar–Apr. Sometimes associates with other icterids, such as *Molothrus bonariensis* and, in interior NE Brazil, *Agelaioides fringillarius*.
Breeding. Season Nov–Mar in C & SE Brazil (both races) and Apr–May in NE (*frontalis*). Mating system sequential or harem polygyny, males spending most of their time in singing and displaying. A few solitary nests, but generally a colonial breeder in or near marshes, also in rice fields; colonies in natural (non-agricultural) habitat small, usually 10–30 nests (six in temperate Buenos Aires province had 6–29 active nests), whereas up to 350 nests per colony reported in rice-growing areas of NE Argentina, Uruguay and S Brazil. Nest built by male, cup-shaped, made from wet plant material (grass and sedges) that dries to a solid structure, external diameter 9–12·5 cm and external

depth 8–10 cm, sited in emergent aquatic vegetation e.g. giant bulrush (*Schoenoplectus californicus*), cat-tails (*Typha*), durazznillo (*Solanum malacoxylon*) and the like, less commonly in tree or shrub e.g. willow (*Salix humboldtiana*), *Sapium haematospermum* or similar, or even eucalypt (*Eucalyptus*) growing near marshes, ditches or rice fields; if female accepts nest, she lines it with thin fibres; a certain number of nests remain unused. Clutch 3–4 eggs, pale blue with few blackish spots and lines around large end, mean dimensions 23·4 × 17 mm (nominate race); incubation by female, period 13 days; chick fed mostly by female, nestling period 13 days; male may defend colony against aerial predators; post-breeding flocks composed only of females and dependent chicks common. Frequent host of *Molothrus bonariensis*, with almost 50% of nests parasitized; parasitism more intense in first months of breeding season.

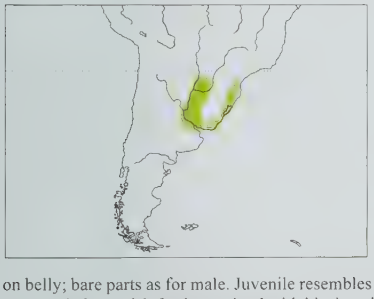
Movements. Little reliable or detailed information. Movements seem to occur mostly in response to droughts and floods, particularly at S edge of range; becomes rare in C Chaco during dry winter season. During severe drought in Nov–Feb of 2008–2009 almost absent from R Paraná delta in Argentina, but numerous flocks arrived within a week of first rains in Mar.

Status and Conservation. Not globally threatened. Common to locally abundant. Expanding its range, notably in C Brazil. Much attracted to rice fields, and regarded as a major agricultural pest in rice-growing areas in S & SE Brazil (especially Rio Grande do Sul), Paraguay, Uruguay and NE Argentina. Attempts to control its population, including use of poisoned baits (causing huge mortality of other birds, too) have not been successful in reducing this species' numbers; also, studies in Argentina suggest that damage done to rice is exaggerated, and partly compensated by the species' consumption of insects harmful to the crop. Elsewhere in its range, this blackbird is usually tolerated. Occurs in several protected areas, including Amboró National Park (Bolivia), Pantanal Matogrossense National Park (Brazil), and Río Pilcomayo, Chaco and Pre-Delta National Parks (Argentina).

Azpiroz (1997), Bello Falavena (1988), Belton (1985), Blanco (1995), Bruggers & Zaccagnini (1994), Di Giacomo (2005), Fraga (2007), Jaramillo & Burke (1999), Klimaitis (1973), Lowther *et al.* (2004), Lyon (1997), Narosky & Di Giacomo (1993), Restall *et al.* (2006), Ridgely & Tudor (1989), Sick (1993).

Genus *XANTHOPSAR* Ridgway, 1901

96. Saffron-cowled Blackbird



Xanthopsar flavus

French: Carouge safran **German**: Gilbstärling **Spanish**: Tordo Amarillo
Other common names: Saffron-crowned Blackbird; Yellow-throated Oriole ("*xantholemus*")

Taxonomy. *O.*[*riolus*] *flavus* J. F. Gmelin, 1788, "in Antigua insulae Panay et America australi" = Río de la Plata, Argentina and Uruguay.

Genus sometimes subsumed in *Agelaius*. Molecular data indicate close affinity with *Pseudoleistes* and more distant relationship to *Chrysomus*, these findings supported by behavioural data. In morphology resembles more the last two genera, but with rather stout tarsometatarsus and thin bill. Form *Icterus xantholemus*, based on a single speciment from S Brazil but erroneously published as from Ecuador, has been shown to be a synonym of present species. Monotypic.

Distribution. SE Paraguay and SE Brazil (from Santa Catarina, rarely Paraná) S to NE Argentina (Corrientes and Entre Ríos) and Uruguay.

Descriptive notes. Male average 20 cm, 42·5 g; female average 39·3 g. Male has hindcrown to back, wing and tail glossy black; rest of head and entire underparts yellow, tinged orange on forehead and breast; yellow epaulet formed by lesser and marginal upperwing-coverts, with similar pattern on underwing; rump yellow; thigh black, rearmost undertail-coverts black with yellow tips; iris orange-brown to deep red-brown; bill and legs black. Female has narrow eyestripe, crown, nape, back, wing and tail brownish-grey, remaining parts of head (including supercilium) and body (including rump) yellow, paler on belly; bare parts as for male. Juvenile resembles female, with rump lemon-yellow; yearling male may retain brownish feathers mixed with black and yellow in head and upperparts. Voice. Song, by both sexes, brief and unmusical, starts with short whistled or warbled notes, ends with rasping "kluiiiiiii". Commonest call "chep"; during nesting, an alarm whistle.

Habitat. Wet grassland, bogs and marshes, usually in open environments. In treeless areas in Argentinian *pampas*, but elsewhere tolerates some arboreal vegetation. In SE Paraguay found in abrupt interface between open grasslands (*campos*) and interior Atlantic Forest, living in large (50–100 ha) natural patches of grassland and marsh surrounded by dense subtropical forest or stands of the arboreal bamboo *Bambusa angustifolia*. Also in rice fields, even when breeding. In Entre Ríos (Argentina) occupies rolling countryside with fertile soils, mostly covered with agricultural fields and cattle pastures. In highlands of Rio Grande do Sul (Brazil) found in grassland near *Araucaria* forest. Up to 1000 m.

Food and Feeding. Insects, spiders (Araneae), small vertebrates (frogs); rarely, seeds (including some cultivated plants). Faecal analyses indicate that insects and spiders comprise bulk of diet; insects consumed represent all main orders, i.e. Hemiptera, Coleoptera, Lepidoptera, Diptera, Hymenoptera. Forages mostly on the ground, where flocks use "rolling" technique. Probes and gapes in soil, and picks prey from grass and low vegetation. Also captures alates of ants (Formicidae) in air. Food for chicks often obtained hundreds of metres from nest or colony. Sociable, in small groups and larger flocks; often associates with other bird species, notably Black-and-white Monjita (*Xolmis dominicanus*), also Streamer-tailed Tyrant (*Gubernetes yetapa*), and with *Pseudoleistes*.

Breeding. Season Oct–Dec, breeding activities in colony usually synchronized; apparently single-brooded. Nests solitarily or in small colonies of up to c. 30–40 nests, in shallow marshes or abandoned rice fields, sometimes on dry land (e.g. most of Entre Ríos, in Argentina). Evidence of possible co-operative breeding, with male helpers at nest. Nest built by female, an open cup made from plant material, mostly grass stems and leaves, lined with plant fibres external diameter 12–15 cm and depth 7–8 cm, placed up to 1 m above ground in emergent marsh vegetation such as *Ludwigia*, aquatic grasses, sedges e.g. *Rhynchospora corymbosa*, or in herbaceous vegetation including weeds such as thistles (*Cirsium vulgare*) or teasels (*Dipsacus fullonum*), or in low shrub e.g. *Baccharis*; a few nests built on the ground. Clutch 3–5 eggs, usually 4, pale with dense brick-red spotting; incubation by female, sometimes fed by male, period 12–13 days; both parents defend nest and feed chicks, nestling period usually 12 days. Nests parasitized by *Molothrus bonariensis*; in Entre Ríos, host chicks outnumber parasite chicks in post-breeding flocks.

Movements. Resident, although subject to some local movements.

Status and Conservation. VULNERABLE. Rare to locally uncommon; declining. Estimated global population 2500–10,000 individuals, and possibly no more than 5000. Range was once larger, but species possibly not common or widespread even in 19th century. In 1800s, range extended from S Brazil and most of Paraguay S over much of N & C Argentina (including rural suburbs of Buenos Aires city) and most of Uruguay; by end of that century, its range had decreased, especially in Argentina, where the species became extinct in most of Buenos Aires Province (last nesting attempt in 1932). Currently, small populations survive in E Paraguay, NE Argentina (parts of Entre Ríos and Corrientes), SE Brazil (mostly Rio Grande do Sul) and S & E Uruguay. Decline probably due to several factors: this species is captured (illegally) for cagebird trade during breeding season, which can destroy entire colonies; habitat destruction through large-scale replacement of natural grassland by pine (*Pinus*) and eucalypt (*Eucalyptus*) plantations, coupled with drainage of wetlands, a serious problem, and was probably a major cause of extinction of populations in Buenos Aires Province; fires during the breeding season, for centuries used as a tool in management of cattle, probably had serious impact; parasitism by *Molothrus bonariensis*, reported as long ago as 1881, no doubt exacerbates effects of other problems. Found in several protected areas, including San Rafael National Park (Paraguay), Aparados da Serra National Park (Brazil), and Bañados del Este Biosphere Reserve, including Potrerillo de Santa Teresa Reserve (E Uruguay). Generally unprotected in Argentina.

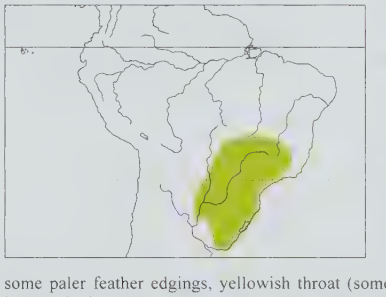
Genus *PSEUDOLEISTES* P. L. Sclater, 1862

97. Yellow-rumped Marshbird



Pseudoleistes guirahuro

French: Carouge guirahuro **German**: Gelbbürzelstärling **Spanish**: Tordo Güirahuró
Other common names: Yellow-rumped Blackbird

Taxonomy. *Agelaius guirahuro* Vieillot, 1819, Paraguay and Río de la Plata.

Closely related to *P. virescens* and to *Xanthopsar flavus*. Monotypic.

Distribution. SE Brazil (S from S Goiás, Minas Gerais and Rio de Janeiro) S to E Paraguay, NE Argentina (Corrientes and N Santa Fe, rarely N Entre Ríos) and N Uruguay.

Descriptive notes. Male average 25·5 cm and 91·2 g; female 81·9 g. Head to upper breast blackish-brown, upperparts brown, except for rich yellow rump; most of wing and tail brown, lesser and median upperwing-coverts rich yellow, similar pattern on underwing; underparts from lower breast to lower belly rich yellow, undertail-coverts brown, narrowly margined yellow; iris brown; bill and legs blackish. Differs from similar *P. virescens* mainly in yellow rump, yellow flanks and generally darker brown and more contrasted appearance. Sexes similar. Juvenile is similar to adult, but duller and browner above, with some paler feather edgings, yellowish throat (sometimes also ear-coverts), paler yellow below, breast with broad brownish streaks. Voice. Song a mix of whistles, warbles, slurs and nasal buzzes, usually slower, less screechy and more pleasant than that of *P. virescens*; commonly vocalizes in group. Common calls are "kwet-kwetéé" and "koink". Often calls and sings in flight.

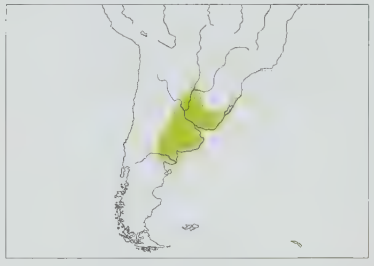
Habitat. Marshes and adjoining uplands, bogs and wet grasslands; also humid or flooded savannas, provided that tree cover not dense. One of the few icterids found in *cerrado*. W of R Paraguay in Paraguay and NE Argentina, occurs locally in marshes in humid Bajo Chaco. Commonly found in rice fields. Lowlands to 1400 m.

Food and Feeding. Insects and other arthropods, small vertebrates, and some seeds. Stomach contents in Paraguay included bugs (Hemiptera) and beetles (Coleoptera). Sometimes feeds on spilled rice left by harvesting machines. Forages on ground and in low vegetation. Has well-developed sentinel behaviour. Found in groups of up to 50 individuals when not breeding; sometimes associates with other icterids, particularly *Xanthopsar flavus*.

Breeding. Season Oct–Jan in Paraguay and Oct–Nov in Brazil (Rio Grande do Sul). Nests solitarily. Co-operative breeder, with up to six helpers at nest. Most nest-building by female, nest a solid and bulky cup of plant material mixed with mud, lined with rootlets and fine grass, placed low down (up to 2·5 m above ground) in herbaceous vegetation or grasses, in emergent marsh vegetation such as cat-tails (*Typha*), or in low shrub or small tree (*Sapium haematospermum*), or even palm (*Copernicia australis*). Clutch 3–6 eggs, white to pinkish-white with reddish-brown, violaceous-grey and purple blotches and spots, mean dimensions 25·6 × 19·3 mm; incubation by female, commonly fed by mate, period 14 days; chicks fed by both parents, also by helpers, estimated nestling period 12 days; soon after fledging, most chicks travel in post-breeding flocks with parents; trios seen at nests in Paraguay and Argentina (Corrientes), also feeding fledglings. Host of *Molothrus bonariensis*, sometimes rearing latter's chicks.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common in most of range; in Argentina common only in N Corrientes and S Misiones; numerous in E Paraguay, but rarer in the Chaco. A single old report from Buenos Aires (Argentina) apparently invalid. Present in several protected areas, including Ybicuí and San Rafael National Parks and Mbaracayú Forest Nature Reserve (Paraguay), Serra do Cipó and Brasília National Parks (Brazil), and Iberá Natural Reserve and Mburucuyá National Park (Argentina).



Bibliography. Azpiroz (1997), Belton (1985), del Castillo & Clay (2004), Di Giacomo (2005), Fraga (2001), Fraga & Di Giacomo (2004), Fraga *et al.* (2003), Hartert & Venturi (1909), Hayes (1995), Jaramillo & Burke (1999), Pacheco *et al.* (1997), Ridgely & Tudor (1989), Sick (1993).

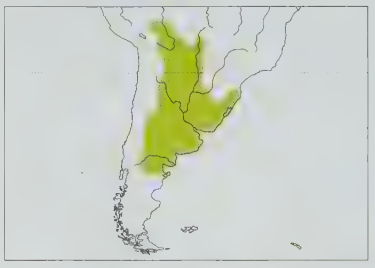
98. **Brown-and-yellow Marshbird**

Pseudoleistes virescens

French: Carouge dragon **German**: Drachenstärling **Spanish**: Tordo Pechiamarillo
Other common names: Yellow-breasted Marshbird

Taxonomy. *Agelaius virescens* Vieillot, 1819, Buenos Aires, Argentina.
Closely related to *P. guirahuro*. Monotypic.
Distribution. Extreme S Paraguay (Ñeembucú) and SE Brazil (Santa Catarina and Rio Grande do Sul) S to EC Argentina (E from E San Luis, S to Buenos Aires, E La Pampa and NE Río Negro) and Uruguay.

Descriptive notes. Male average 24 cm, 79·6 g; female average 72·9 g. Head to upper breast, upperparts and most of wing are deep brown to olive-brown, lesser upperwing-coverts and bend of wing rich yellow, forming very small epaulet (visible in flight) with similar pattern on underwing; tail deep brown to olive-brown; lower breast and belly rich yellow, flanks, thighs and undertail-coverts olive-brown; iris brown; bill and legs blackish. Differs from *P. guirahuro* in browner and less colourful appearance and brown rump. Sexes similar. Juvenile is similar to adult, but throat yellowish and breast striped pale yellow and brownish, lower mandible yellowish; this plumage lasts for only a short time. Voice. Noisy. Song a mixture of call notes, a series of screechy chattering notes mixed with ascending or (rarely) descending whistles. A common call, by both sexes, a loud repeated "chrrr-wéé", often given in chorus before flock departs; usual alarm call a loud wooden rattle. Much group calling, even in flight.
Habitat. Marshes and wet grasslands, pastures, even agricultural fields and roadsides; sometimes in treeless areas. Locally common in rolling and rocky landscapes near streams, e.g. Sierra de la Ventana, in Buenos Aires (Argentina). Commonly roosts in emergent vegetation in marshes or in tall grass clumps, e.g. *Panicum prionites* and pampas grass (*Cortaderia selloana*). Lowlands; non-breeding visitors reported occasionally to 2100 m in NW Argentina.
Food and Feeding. Insects and other arthropods, small vertebrates, rarely seeds. Arthropod prey include spiders (Araneae), particularly wolf spiders (Lycosidae), also beetles (Coleoptera), Orthoptera and Lepidoptera. Spiders formed 13% and seeds 7% of stomach contents. Forages on ground, probing and gaping in soil or in low vegetation; will turn over objects (such as cow dung) to find hidden items. Forages in flocks, usually leaving some individuals as sentinels. In non-breeding season flocks reportedly contain up to 40–50 individuals; associates with other ground-feeding icterids, such as cowbirds and *Xanthopsar flavus*, less commonly with its congener *P. guirahuro*.
Breeding. Season Aug–Dec in Argentina; starts to nest earlier than sympatric icterids, some fledglings by end of Sept. Co-operative breeder, with up to six helpers. Commonly in small groups or colonies, inter-nest distance variable, sometimes as little as 4 m. Appears to be non-territorial. Nest-building mostly by female, nest a solid bulky cup of plant material mixed with mud, lined with rootlets and fine grass, placed low down in herbaceous vegetation such as pampas grass, introduced thistles (*Cynara* and *Carduus*), cat-tails (*Typha*) or similar, or in low shrub or small tree (*Sambucus australis*, *Celtis spinosa*). Clutch 3–6 eggs, white with reddish-brown blotches and spots; incubation by female, commonly fed by mate, period 14 days; chicks fed by both sexes, assisted by helpers, nestling period 11–12 days; soon after fledging, most chicks and their families travel in post-breeding flock. Nests parasitized by *Molothrus bonariensis* and *Molothrus rufoaxillaris*; rears chicks of these.
Movements. Apparently non-migratory, but flocks move considerable distances in non-breeding season. Possibly only accidental in NW Argentina (Jujuy, Salta and Tucumán), where flocks reported too irregularly to constitute true migration; movements perhaps linked to floods during rainy years.
Status and Conservation. Not globally threatened. Common and rather widespread, particularly in EC Argentina and Uruguay. Drainage of wetlands may have eliminated some areas of suitable habitat in the Pampas, but this species seems quite tolerant of moderate human disturbances. Present in several protected areas, including Otamendi Reserve (Argentina), Lagoa do Peixe National Park and Taim Ecological Station (Brazil) and Bañados del Este Biosphere Reserve (E Uruguay).
Bibliography. Azpiroz (1997), Belton (1985), Darrieu & Camperi (1998), Darrieu *et al.* (1996), Duré Ruiz *et al.* (2008), Fraga (2002), Fraga *et al.* (2003), Gibson (1918), Jaramillo & Burke (1999), Mermoz & Reboreda (1994, 1996, 1998, 1999, 2003), Narosky & Di Giacomo (1993), Nores & Yzurieta (1980), Orians (1980), Orians, Orians & Orians (1977), Ridgely & Tudor (1989), Svagelj *et al.* (2009).



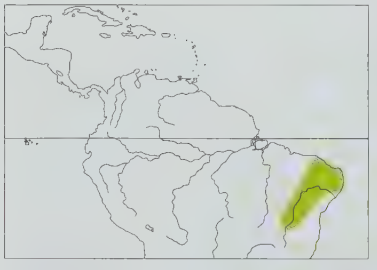
Genus *AGELAIOIDES* Cassin, 1866

99. **Greyish Baywing**

Agelaioides badius

French: Carouge à ailes baies **German**: Graukuhstärling **Spanish**: Tordo Músico
Other common names: Bay-winged Cowbird, Baywing

Taxonomy. *Agelaius badius* Vieillot, 1819, Paraguay.
Genus formerly subsumed in *Molothrus*. Sometimes treated as conspecific with *A. fringillarius*, but the two differ in plumage coloration, vocalizations and some details of social behaviour. Behaviour suggests close relationship with monotypic genera *Gnorimopsar* and *Oreopsar*, and this is supported by molecular data. Races probably intergrade in Bolivia. Two subspecies recognized.
Subspecies and Distribution.
A. b. badius (Vieillot, 1819) – E Bolivia (Beni) and S Brazil (Mato Grosso do Sul and Rio Grande do Sul) S to S Argentina (N Chubut) and Uruguay.
A. b. bolivianus (Hellmayr, 1917) – C & S Bolivia.
Descriptive notes. Male average 18·6 cm, 46·6 g; female average 18·4 cm, 43·7 g. Nominate race is brownish-grey overall, with blackish lores and narrow mask around eye; upperwing blackish,



feathers with broad rufous edgings (wing appears rufous), tail blackish with narrow brownish or greyish fringes; iris dark brown; bill and legs black. Differs from juvenile of *Molothrus rufoaxillaris* (which closely mimics that of present species) mainly in smaller size, shorter wing, somewhat smaller bill, paler wing-linings. Sexes similar. Juvenile is similar to adult, but mask not so dark, outer tail feathers edged rufous, inside of mouth pinkish (rather than black). Race *bolivianus* is very similar to nominate, but slightly larger and on average somewhat greyer in coloration. Voice. Song, by both sexes, slow, musical and continuous, a mix of trills, whistles, slurs, warbles and short buzzing notes; quite variable among individuals. Much group singing, particularly around roost. Contact calls "chuck" and a loud whistle, "peeh".
Habitat. Open woodland, savanna and scrub, from mesic to xeric. Prefers edges or clearings, and rare within dense unbroken woodland; almost absent from Atlantic Forest in E Paraguay and NE Argentina (Misiones). Common in *chaco* woodland with *Prosopis*, *Aspidosperma*, *Schinus* and similar, and arborescent cacti; seen also in palm savannas with yatay palm (*Butia yatay*). In the Monte Desert of W Argentina usually near water or in the most humid locations, but visits nearby scrub. Nowadays frequents agricultural and pastoral land, parks, plantations, gardens, even suburbs of large cities (e.g. Buenos Aires, Argentina). Nominate race from lowlands to 3100 m (in NW Argentina); *bolivianus* in montane valleys at up to 3200 m.
Food and Feeding. Seeds, insects (particularly Orthoptera and Lepidoptera) and other invertebrates, including spiders (Araneae) and amphipods; also some fruit, and rarely nectar, latter from flowers of introduced Australian trees such as eucalypts (*Eucalyptus*) and *Grevillea*. Seeds predominate in stomach contents. In agricultural areas feeds on cultivated seeds of e.g. maize (*Zea mays*), sunflower (*Helianthus*) and sorghum, but also on weed seeds (*Chenopodium*, *Amaranthus*, thistles). Nestling diet includes large mantids (Mantidae). Forages on bare ground, also in dense vegetation such as weed-covered fields; also arboreal, commonly foraging in branches and leaves of trees and shrubs. Sometimes uses a foot to hold food items. Usually in small groups; in non-breeding season also in larger flocks of up to c. 25 individuals.
Breeding. Season Oct–Mar in Argentina; usually single-brooded. Nests solitarily; usually territorial. Co-operative breeder, with up to four helpers present at most nests in Argentina; helpers commonly related to breeders, usually males 1–3 years old. Nest built by female, a loose or a well-made cup (depending on the site) of plant material (gathered from around nest), hair and some feathers, site variable, but usually covered or closed, often inside hole or crevice in tree, at base of palm frond or, more rarely, within thick foliage or among epiphytic bromeliads; avoids very dark sites, but may nest in shallow nestbox; commonly nests inside closed structure built by another species, mostly furnariid such as Rufous Hornero (*Furnarius rufus*), Firewood-gatherer (*Anumbius annumbi*), thornbird (*Phacellodomus*) or Brown Cacholote (*Pseudoseisura lophotes*), sometimes that of *Procacicus solitarius* or Great Kiskadee (*Pitangus sulphuratus*); utilizes old and rather ruined structure (particularly nest of Rufous Hornero) or new one, sometimes through piracy. Clutch 3–5 eggs, variable in colour (buff, greyish or bluish), always spotted or marked in shades of brown; incubation by female, period 13 days; chicks fed and preened by both sexes, also by any helpers present, nestling period usually 13–14 days; male guards nests throughout cycle; territory abandoned soon after chicks fledge, post-breeding groups coalesce into flocks, and fledglings fed by several adults for almost a month. Nests frequently parasitized by *Molothrus rufoaxillaris*, e.g. 80% of nests in NE Argentina study, and present species found to fledge on average one parasite chick for every three of its own chicks. Also parasitized by *M. bonariensis*.
Movements. Apparently resident. Accidental in C Chile.
Status and Conservation. Not assessed. Common and widespread; locally abundant. Quite adapted for living in modified environments. Has colonized N Patagonia (in S Argentina) and increased in numbers and distribution. Reports from São Paulo, Goiás and other places in EC Brazil are erroneous, being referable to misidentified mimetic *Molothrus rufoaxillaris* juveniles. Although impact of brood parasitism by latter species appears not to be heavy, present host seems more abundant in areas where *Molothrus rufoaxillaris* absent (e.g. Cochabamba Valley, in Bolivia, in 1990s). Found in many protected areas, including, among others, Kaa-Iya del Gran Chaco National Park (Bolivia), Pantanal Mato-grossense National Park (Brazil), and El Palmar, Pre-Delta and Chaco National Parks (Argentina).
Bibliography. Azpiroz (1997), Belton (1985), Beltzer (1988b), De Mársico & Reboreda (2010), De Mársico *et al.* (2010), Di Giacomo (2005), Fraga (1972, 1979, 1983b, 1984, 1986, 1988, 1991, 1992, 1998, 2004, 2006, 2008b), Friedmann (1929), Jaramillo & Burke (1999), Mason (1980), Orians, Orians & Orians (1977).

100. **Pale Baywing**

Agelaioides fringillarius

French: Carouge de Spix **German**: Braunkuhstärling **Spanish**: Tordo de Spix
Other common names: Spix's Baywing

Taxonomy. *Icterus fringillarius* Spix, 1824, Minas Gerais, Brazil.
Genus formerly subsumed in *Molothrus*. Sometimes treated as conspecific with *A. badius*, but the two differ in plumage coloration, vocalizations and some details of social behaviour. Monotypic.
Distribution. Interior of NE Brazil from Piauí, Ceará and W Rio Grande do Norte S to N Minas Gerais.

Descriptive notes. Male 17·5 cm, 40·1 g. Plumage is pale sandy brown overall, paler on rump, with blackish lores and narrow mask around eye, greyish-brown ear-coverts; upperwing blackish-brown, feathers with broad rufous-cinnamon edgings (wing appears mostly rufous), dusky tail; iris dark brown; bill and legs black. Differs from juvenile of *Molothrus rufoaxillaris* (which closely mimics that of *A. badius*) mainly in smaller size, shorter wing, somewhat smaller bill, paler wing-linings. Sexes similar. Juvenile is similar to adult. Voice. Song (possibly by both sexes) a slow, hesitant sequence of descending whistles mixed with calls, softer, more plaintive and less varied than that of *A. badius*; group

singing occurs. Many rasping or chattery calls somewhat resembling those of *Pseudoleistes*, including "kwoink" contact call; calls likened to those of House Sparrow (*Passer domesticus*).
Habitat. Edges and clearings in *caatinga* (dry forest), second growth of the same, and modified environments such as pastures and crop fields. Commonly seen around human habitations in rural properties (*fazendas*) in the *caatinga*, and breeds even in small towns. Mostly below 800 m.
Food and Feeding. Seeds and arthropods; once, a group attempted to catch small lizards. Seeds often of cultivated plants, such as maize (*Zea mays*) and sorghum. Forages mostly on the ground, commonly in corrals, barnyards and pig pens. In pairs and in small flocks of up to c. 20 individuals; associates at roosts with *Chrysomus ruficapillus*, *Molothrus bonariensis* and House Sparrows.
Breeding. Season Jan–Apr in N of range (Rio Grande do Norte) and Nov–Jan in S (Minas Gerais). Co-operative breeder, with up to six helpers present at most nests. Nest a loose or well-made cup of plant material, hair and feathers, placed inside closed nest built by other species, particularly the furnariid Rufous-fronted Thornbird (*Phacellodomus rufifrons*), sometimes another furnariid, e.g. Caatinga Cachalote (*Pseudoseisura cristata*) or Chotoy Spinetail (*Schoeniophylax phryganophilus*), less commonly in natural hole or crevice in tree or at base of palm frond. No information on clutch size and on duration of incubation and nestling periods; old reports that eggs white and unmarked require confirmation (eggs perhaps those of *Molothrus bonariensis*); helpers guard nest, mob predators and bring food, aggressive interactions with pairs of *Icterus jamacaii* (nest-site competitor and potential predator) can involve whole group. Nests parasitized by *Molothrus bonariensis*; is also a potential host of *Molothrus rufoaxillaris*, expanding in N Brazil.
Movements. Apparently sedentary.
Status and Conservation. Not assessed. Uncommon to locally fairly common; has reasonably extensive distribution. Adapts to human-modified environments.
Bibliography. Fraga (2006, 2008b), Friedmann (1929), Jaramillo & Burke (1999), Pacheco (2000).

Genus *OREOPSAR* W. L. Sclater, 1939

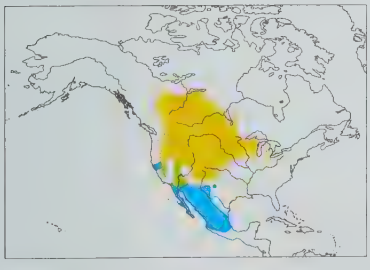
101. **Bolivian Blackbird**

Oreopsar bolivianus

French: Carouge de Bolivie **German**: Andenstärling **Spanish**: Tordo Boliviano

Taxonomy. *Oreopsar bolivianus* W. L. Sclater, 1939, Sucre, 2700 m, Chuquisaca, Bolivia.
Mitochondrial DNA data indicate that this species could be sister to *Agelaioides badius*, but in general aspect, skeletal morphology and behaviour it also resembles *Gnorimopsar chopi*. Proposal to merge present genus into *Agelaioides* would require name of present species changing to *A. oreopsar*, as name "*bolivianus*" preoccupied therein. Monotypic.
Distribution. C Bolivia, mostly in Cochabamba, Potosí and Chuquisaca, probably also in nearby parts of La Paz and Oruro.

Descriptive notes. Male 23 cm, average 73·5 g; female average 66·2 g. Medium-sized, all-dark icterid, bill with decurved culmen. Plumage is almost entirely black, with little iridescence; flight-feathers sepia-brown, conspicuous in flight; iris brown; bill grey; legs dusky grey. Differs from *Molothrus bonariensis* in larger size and lack of obvious iridescence; from *Gnorimopsar chopi* in brownish wings. Sexes similar. Juvenile resembles adult, but with brownish tinge on upperwing-coverts and underparts. Voice. Song a simple sequence of short "chip" notes interspersed with "chip-it" notes, simpler, less harmonious and higher-pitched than that of *Gnorimopsar chopi*. Calls include "chu-pee" as contact and "pee" flight call, reminiscent of those of both *Agelaioides badius* and *Gnorimopsar chopi*; also a dry rattle.
Habitat. Dry intermontane valleys (six or more months of dry season). Often in open xeric woodland (with *Prosopis*, *Acacia*, *Schinus*, arborescent cacti, etc.) and scrub; commonly seen in irrigated and cultivated land in such sites, even around rural buildings. Usually not far from cliffs used for nesting. At 1400–3500 m.
Food and Feeding. Insects and other arthropods; also seeds, including crop seeds i.e. maize (*Zea mays*), and cactus fruits. Usually forages on ground, often probing and gaping in soil; also gleans prey from leaves and branches of trees and shrubs. May use gaping as means of opening sacks of maize. Invariably in medium-sized groups, containing up to c. 20 individuals; may join flocks of other icterids, particularly *Agelaioides badius* or *Gnorimopsar chopi*.
Breeding. Season Apr. Co-operative breeder. Nest a loose open cup of plant material, placed in hole or crevice in rocky wall or cliff; material shaped so as to fill cavity. Clutch 3 eggs, pale greenish-grey with spots and blotches in brown and black, mean dimensions 26·6 × 19·6 mm; no information on incubation and nestling periods; several individuals may feed chicks.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Locally common in suitable habitat. Tolerates some habitat disturbance. Found in some protected areas, e.g. Tunari National Park (near Cochabamba).
Bibliography. Fraga (2004), Jaramillo & Burke (1999), Lowther (2001), Orians (1985a), Orians, Eckermann & Schultz (1977), Ridgely & Tudor (1989), Sclater (1939), Vuilleumier (1969a), Webster (2003).



Genus *XANTHOCEPHALUS* Bonaparte, 1850

102. **Yellow-headed Blackbird**

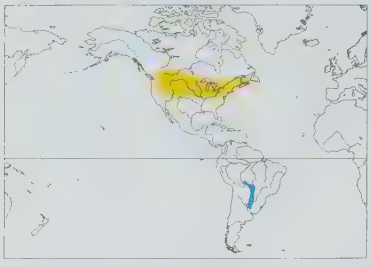
Xanthocephalus xanthocephalus

French: Carouge à tête jaune **German**: Brillenstärling **Spanish**: Tordo Cabeciamarillo

Taxonomy. *Icterus xanthocephalus* Bonaparte, 1826, Nebraska, USA.
Analyses of mitochondrial DNA indicate that this species is distantly related to *Sturnella*; resembles *Agelaius* in breeding ecology, but displays quite different. Monotypic.
Distribution. Breeds in SC Canada (from interior British Columbia E to N Saskatchewan, SC Manitoba and SW Ontario) S in W & C USA to California, C New Mexico, N Kansas, N Illinois and Michigan and extreme NW Mexico (NE Baja California); migrates to S USA and Mexico (S to N Oaxaca and Veracruz).

Descriptive notes. Male average 26·5 cm, 97 g; female average 21·5 cm, 59·3 g. Male has lores and narrow area around eye black, rest of head, throat and breast bright yellow (crown and nape feathers with yellowish-brown tips in non-breeding plumage); upperparts, including wing and tail, black, primary coverts, some outer greater coverts and part of alula white; underparts below breast black, yellow patch on lower belly; iris dark brown; bill and legs black. Female is smaller than male, has lores greyish, forehead to nape and neck brown, ear-coverts similar, superciliary line, area surrounding ear-coverts and moustachial stripe pale yellow, throat whitish and upper breast yellow; rest of plumage brown to brownish-black; bare parts as for male. Juvenile has cinnamon-buff head and underparts, dark facial mask, brownish upperparts with cinnamon tips and edges above, two pale wingbars, male lighter, more tawny above and with whiter wingbars than female, latter with darker back and buff wingbars. Voice. Male has two song types: "accenting song" is more musical, lasts for c. 1·5 seconds and is directed towards distant conspecifics; "buzzing song", c. 4 seconds and directed at close conspecifics, is distinctive and rather dissonant, has been likened to sound of an unwinding clock machine or even the braying of an ass. Female produces a chatter, equivalent to male song. Common call a hoarse "chuk" or "chek", deep and hollow in quality; alarm a harsh rattle by male, screaming chatter by female.
Habitat. Wetlands in prairies, also wetlands associated with quaking aspen (*Populus tremuloides*), and lake edges. In non-breeding season also agricultural land, pastures, mountain meadows. Mainly in lowlands; to 2500 m in winter quarters. Flocks usually roost in marshes.
Food and Feeding. Contents of 138 adult stomachs were 66% plant food and 34% animal food. Vegetal items predominantly weed seeds and cultivated seeds, the former mostly *Panicum*, *Echinochloa*, *Ambrosia* and *Polygonum*, the latter included wheat, oats and maize (*Zea mays*); insects comprised mostly beetles (Coleoptera), Orthoptera and Lepidoptera. Nestling diet 60–90% insects, particularly emergent dragonflies and damselflies (Odonata); small amounts of grass seeds, grains and molluscs also fed to young. Forages mostly on ground in cropland and grassland, also around wetlands. Post-breeding flocks of several thousands to many thousands of individuals, often segregated by sex; on migration often in mixed flocks with other icterids.
Breeding. Season May–Jun; single-brooded. Polygynous; in Washington (USA) mean number of females per male territory or harem varied from 1·7 to 4·2 (range 0–8). Breeds in semi-colonies of grouped male territories, with several hundred nests; male defends territory of 100–600 m² (some food obtained within territory); females arrive later than males and defend small area (minimum size c. 1 m²) around nest; male expels *Agelaius phoeniceus* from main nesting habitat in deep-water marshes. Female may start nest-building three days after arrival, completing work in average of 4–5 days; nest cup-shaped, neatly built from long, interlaced wet strips of plant material, further (non-interlaced) plant material forms inner wall, lined with fine grasses or other plumose vegetation, external diameter 13–14 cm, external height 13–15 cm; built in living or dead emergent water plants such as cat-tails (*Typha*), rushes (*Scirpus*) or reeds (*Phragmites*) growing in water 30–110 cm deep, and firmly attached to minimum of 4–5 plant stems (up to 30 stems and leaves if built in cat-tails), sometimes in willow (*Salix*) or tamarix (*Tamarix gallica*) in flooded areas. Clutch 2–5 eggs, usually 3–4 (2-egg clutches typical of renesting females), greyish-white to pale greenish-white, densely blotched and spotted in brown, rufous and grey, mean dimensions 26·3 × 18·1 mm; incubation by female, generally beginning when second egg laid, period 12–13 days; hatching usually asynchronous, chicks fed by both sexes, female more constantly, male feeds chicks from day 4 after hatching (but feeds mostly chicks of primary, earlier-breeding females; chicks of secondary females fed mostly if broods of primary female smaller); nestling period 9–14 days; males with larger harems devote less time to brood-feeding, and will not feed fledglings that leave their territory; both sexes attack nest predators. Normally parasitized only infrequently by *Molothrus ater*, and rears few of latter's chicks; of 266 nests in Washington (USA) only two (0·75%) were parasitized, but in Idaho four of 19 nests (21%) were; unlike other large hosts, present species does not remove parasite's eggs.
Movements. Medium-distance and long-distance migrant. Winters in S USA (mainly C California E to New Mexico) and S to C Mexico (Michoacán, Guerrero, Puebla and N Oaxaca). Diurnal migrant. Leaves breeding grounds from late Aug and Sept (some failed breeders in Jul), last ones in Oct, arriving in non-breeding quarters from Aug/Sept; sexes migrate separately, majority of males wintering in SW USA, whereas females move farther S. Return migration begins Feb–Mar, with arrival of males in breeding areas from Mar, later (May–Jun) in N of range; females reach nesting areas 1–2 weeks after males. Vagrants recorded widely throughout E North America, also Bahamas, Cuba, Cayman Is and Yucatán Peninsula.
Status and Conservation. Not globally threatened. Fairly common to uncommon, and locally numerous; generally uncommon in S of range. In Mexico, very local and uncommon breeder, and more widespread and fairly common non-breeding visitor. Despite some loss of wetland habitat, is still a reasonably widely distributed species. Populations in some US states, such as Illinois, are declining and are of local conservation concern. Occurs in several protected areas in Canada and USA.
Bibliography. Arnold (1992), Barber & Evans (1995), Bent (1958), Briskie (1994), Bump (1986), Cash & Johnson (1990), Collins (2003), Cosens & Falls (1984), Crawford (1977), Dufty (1994), Fautin (1941), Gori (1988a, 1988b), Jaramillo & Burke (1999), Lanyon & Omland (1999), Leonard & Picman (1986), Lightbody & Weatherhead (1987), McCarthy (2006), Nero (1963), Orians (1966, 1980), Orians & Christman (1968), Orians & Willson (1964), Ortega & Cruz (1991), Picman & Isabelle (1996), Price (1996), Proctor & Donald (2003), Richter (1984), Rohwer & Roskaft (1989), Twedt & Bleier (1991), Twedt & Crawford (1995), Twedt *et al.* (1994), Westmoreland & Kiltie (1996), Willson (1966a).

Genus *DOLICHONYX* Swainson, 1827



103. **Bobolink**

Dolichonyx oryzivorus

French: Goglu des prés **German**: Reisstärling **Spanish**: Tordo Charlatán

Taxonomy. *Fringilla oryzivora* Linnaeus, 1758, South Carolina, USA.
Distinctive, and has sometimes been placed in a subfamily of its own (Dolichonychinae). Nesting habits resemble those of *Sturnella*, but mitochondrial DNA indicates only distant relationship with latter. Monotypic.
Distribution. Breeds across S Canada (interior SE British Columbia E to S Ontario, S Quebec and Nova Scotia, to E Newfoundland) S in USA to Oregon, N Colorado, Nebraska, C Illinois and Virginia; migrates to non-breeding grounds mostly in E Bolivia (Beni and Santa Cruz), SC Brazil (Pantanal of Mato Grosso), Paraguay, and N Argentina (R Paraná basin S to Buenos Aires).
Descriptive notes. 16–18 cm; male average 47 g, female average 37·1 g. Emberizid-like icterid with long, pointed wings and sharply pointed tail feathers. Male breeding has large, variable pale buffish nape patch, rest of head, throat and entire underparts black; upper back black with long buff streaks (central stripe widest), lower back and rump pale grey, becoming whitish on uppertail-coverts; tail black; scapulars white, upperwing and its coverts black, inner greater coverts and tertials with white fringes, primaries

On following pages: 104. Red-breasted Blackbird (*Sturnella militaris*); 105. White-browed Blackbird (*Sturnella superciliaris*); 106. Pampas Meadowlark (*Sturnella defilippii*); 107. Peruvian Meadowlark (*Sturnella bellicosa*); 108. Long-tailed Meadowlark (*Sturnella loyca*); 109. Lilian's Meadowlark (*Sturnella lilianae*); 110. Eastern Meadowlark (*Sturnella magna*); 111. Western Meadowlark (*Sturnella neglecta*).

with narrow white edges; iris dark brown; bill black, grey base of lower mandible; legs brownish-flesh to dark brownish-grey. Non-breeding male is like female breeding, sometimes with blackish spots on throat; male in late austral summer (Feb–Mar) generally has plumage intermediate between breeding and non-breeding. Female breeding has head mostly pale buff, including long, broad supercilium bordered below by dark postocular stripe and above by dark crown, which is dusky with narrow brownish feather edges, with a well-defined pale buff central crown stripe (broadest at rear); upperparts buff with broad black or dusky-brown streaks; upperwing dark brown, all feathers fringed pale buffish to grey; tail dusky greyish, feathers edged paler; throat whitish, underparts creamy buff, flanks and belly with dusky stripes; bill pinkish or flesh-coloured, usually palest at base of lower mandible, often dusky at tip and along culmen; legs pinkish-grey. Non-breeding female is similar to breeding, but brighter, feathers of upperparts having warmer golden-buff or orangey edges, face and underparts with richer orange-buff tone, bill brighter pink. Juvenile resembles non-breeding female, but feathers of upperparts have thin buff fringes (looking scaly), and underparts entirely buff and unstreaked except for few thin dark streaks on side of breast. VOICE. Song, by male only, in flight or from perch, a pleasant, fast series of warbles, gurgles and some whistles; two song types, each composed of 25–50 notes, and lasting 0·5–11 seconds; main frequency range 1150–7450 Hz, with much individual and dialectal variation. Commonest call, by both sexes, "ping" or "pink", given often in flight; other calls include soft "chuk", also "tchek" by male during territorial chases, "zeep" by female in aggression towards other females.

Habitat. In breeding season mostly wet meadows; commonly also hay fields, pastures of alfalfa (*Medicago*) and clover (*Trifolium*), and wheat fields. Avoids woodlands. In non-breeding quarters (and during migration) found mostly in emergent or floating vegetation in tropical to subtropical marshes, also riparian environments, wet grasslands and pastures, and particularly rice fields. Mostly in lowlands in both breeding and non-breeding ranges; one record from as high as 3400 m in Cochabamba (Bolivia).

Food and Feeding. Seeds and insects. On breeding grounds stomach contents indicate 57% arthropods, including beetles (Coleoptera), Lepidoptera, Hymenoptera and Orthoptera, and 43% seeds and other plant food; seeds consumed include those of crop cereals (particularly rice), but also agricultural weeds. During migration and in winter quarters feeds on rice, also on seeds of wild grasses such as species of *Paspalum*, *Echinochloa*, *Leptochloa* and others. Forages mainly on ground and low in vegetation. In pairs, small groups and larger flocks. Non-breeding flocks containing thousands of individuals reported, and 90,000 in a roost in Bolivia. In South America associates in mixed-species foraging flocks with *Sporophila* seedeaters, often eating same grass seeds; loosely associates also with other local icterids, including *Sturnella superciliaris* and *Sturnella militaris*.

Breeding. Season May–Jul; usually single-brooded. Monogamous to polygynous. Male defends territory of 0·5–2 ha, containing 1–4 nesting females. Male helpers reported as feeding chicks at a few nests. Nest placed on ground, usually concealed by dense vegetation, built by female, starting by creating slight depression in ground or deepening an existing one; nest cup-shaped, composed of coarse, dead grass leaves and weed stems, entirely lined with very fine grasses or sedges, internal diameter c. 9 cm, internal depth c. 3 cm; about a third of nests covered by loose dome of plant material. Clutch 4–7 eggs, pale grey to pale rufous-brown, spotted and blotched in shades of brown and violaceous grey, mean dimensions 21·7 × 16·2 mm; incubation by female, period 12–13 days; chicks fed by both sexes, female more constantly, polygynous males feed mostly chicks of first two nests in territory; nestling period 9–12 days.

Movements. Long-distance migrant. Entire population migrates to C South America, making round trip of c. 20,000 km every year between breeding and non-breeding quarters; main wintering areas include the Pantanal, the Beni savannas (Bolivia), rice-growing areas of Santa Fe (Argentina), and E Chaco. Migrates in large flocks; c. 20,000 individuals, spread over a few flocks, observed on N passage in Paraguay. Leaves breeding areas mainly in Aug (after moult), passing mostly along E US seaboard and through Greater Antilles (especially Cuba and Jamaica), also across open W Atlantic Ocean, reaching N coasts of South America from late Oct; arrival in Brazil and Paraguay in Nov, and often not until Jan in S part of non-breeding quarters in Argentina. Within main wintering grounds in C South America flocks move in search of seasonal seeds, including rice. Return migration starts in Mar, some remaining in Argentina until early Apr; route apparently more to W than that in autumn; arrives in S USA from Apr, and back in breeding areas mostly in Apr and early May, a few not until Jun in N. Females arrive on breeding grounds c. 1 week after males. Smaller flocks regularly reported in autumn along Pacific coast from Ecuador (including Galapagos Is) S to Chile, and possibly an additional wintering area exists in this region; further study required. Recorded as a passage migrant over most of Central America and N South America. Accidental in Greenland, E Atlantic islands (Canaries, Azores) and W Europe (British Is, France, Norway, Italy).

Status and Conservation. Not globally threatened. Common to locally abundant; less numerous at periphery of breeding range. Declining in numbers; continues to suffer loss of breeding habitat (hayfields and meadows) in Canada and USA, and adversely affected by pesticide use. Flocks containing several thousands of individual still reported in Argentina. Formerly was widely hunted for food in S USA; this still happens in Jamaica and other places, where well-fattened migrants can provide good nourishment for local human populations. On wintering grounds sometimes captured for the pet trade in Argentina, and commonly regarded as a pest in rice-growing areas of Bolivia and Argentina. Found in many protected areas both in its breeding range and on its wintering grounds.

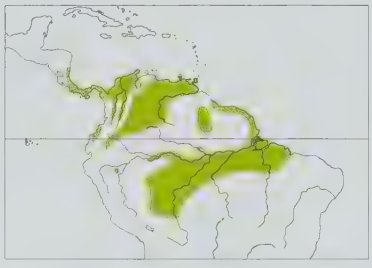
Genus *STURNELLA* Vieillot, 1816

104. **Red-breasted Blackbird**

Sturnella militaris



French: Sturnelle militaire **German**: Rotbruststärling **Spanish**: Loica Pechirroja

Other common names: Northern Marsh Meadowlark

Taxonomy. *E.[mberiza] militaris* Linnaeus, 1758, Suriname.

Formerly placed with *S. superciliaris* in a separate genus, *Leistes*, but molecular data indicate close affinity with present genus. Closely related to *S. superciliaris*, and the two may form a superspecies; sometimes considered conspecific, but ranges overlap locally in SE Peru (E Madre de Dios), NE Bolivia (Pando and N Beni) and NE Brazil (NE Pará, Maranhão and N Tocantins) with no evidence of interbreeding, and no intermediates or hybrids between the two have been reported; range overlap sometimes attributed to seasonal N movements by *S. superciliaris*, but verification required. Monotypic.

Distribution. Extreme SE Nicaragua S to Colombia, Venezuela, Trinidad, the Guianas, Amazonian Brazil (Acre, Rondônia, Amapá, Pará, N Tocantins and Maranhão), NW & NE Ecuador, Peru (Loreto; Madre de Dios), and NE Bolivia (Pando, Beni).

Descriptive notes. Male average 19 cm and 53 g; female average 18 cm and 46·1 g. Male is mostly blackish on head and upperparts; chin, throat and breast bright crimson-red, marginal and most of lesser upperwing-coverts and marginal underwing-coverts red, belly and vent black; when freshly moulted (non-breeding plumage), black feathers have buff edges (giving striped appearance) and red breast feathers are tipped buff (barred appearance); iris blackish-brown; bill black, sometimes dark brown to black with horn-coloured or grey base of lower mandible; legs horn-coloured to brownish-black. Female is streaked blackish and buff on head and upperparts, with pale buff supercilium and median crownstripe, some red in marginal upperwing-coverts; throat and underparts buff, palest on throat, streaked dusky brown on breast and flanks, centre of underparts tinged with pink, undertail-coverts narrowly barred blackish; in fresh plumage (non-breeding), more boldly patterned, with more obvious streaks; bill horn-coloured, often duskier on upper mandible, palest at base of lower mandible; legs fleshy-horn to dark grey. Juvenile resembles female, but all feathers of upperparts and upperwing-coverts fringed pale (scaly appearance), more extensively streaked below, no hint of red in plumage. VOICE. Male song, from perch or in aerial display, varies among populations, consists of 1–5 brief notes (clicks, warbles) followed by dissonant buzz, usually ending in a few short notes; buzzing part of song usually harsher and more strident than that of *S. superciliaris*. Call "ee", also "pist" as alarm; several other calls reported.

Habitat. Savanna and lush grassland, often near water; also agricultural land, including rice fields. In Amazonia partial to cattle pastures (natural and planted) in *várzea*, but also in grassy clearings, including airfields. Seems to breed mostly in lowlands below 600 m, but reported at up to 1855 m in NE Ecuador; from sea-level up to 800 m in NW Ecuador.

Food and Feeding. Insects and other arthropods, also seeds (including rice), rarely fruit. Forages on or near ground. Sociable; commonly in flocks of up to c. 100 individuals, occasionally more.

Breeding. Season May–Aug in Costa Rica, Mar–Dec in Trinidad, Jan–Nov in Suriname, and Jan–Apr in Colombian lowlands (Jun at higher elevations); in Venezuelan *llanos* breeds at start of rainy season (May–Jun), stops during floods of the full rainy season, and nests again during early dry season (Nov). Possibly polygynous. May breed in loose colonies in dense grasslands, pastures or crop fields. In short flight display, male parachutes to ground while singing, with red epaulets flared. Nest probably built by female alone, a deep cup of grass stems and other plant material, in Trinidad reportedly lined with fine grass or plant down, placed on ground among thick overhanging vegetation, often at base of grass clump; sometimes tunnel in surrounding vegetation leading to the nest. Clutch 2–4 eggs, mean 2·9 in Venezuela, pale blue or pale cream, densely marked with dark reddish-brown, mean dimensions 23·4 × 17·2 mm; incubation probably by female alone, but details of parental roles lacking; no information on incubation and nestling periods. Frequent host of *Molothrus bonariensis*; of 14 nests in Venezuelan *llanos* ten held eggs of latter, but parasitism probably rarer in Nov season. In Venezuelan study, c. 50% of nests produced fledglings.

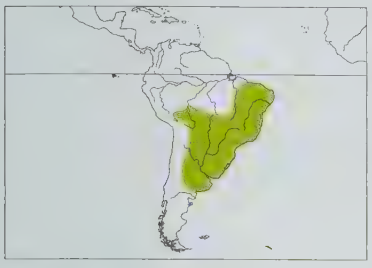
Movements. Resident. Some seasonal movements reported in areas with strong dry season (e.g. *llanos* in Venezuela).

Status and Conservation. Not globally threatened. Rather common. Extending its range N as a result of deforestation; invaded Costa Rica in 1970s, and recently reported in Nicaragua. Also expanding through Amazonia. Formerly restricted to natural savannas, but has adapted to agricultural landscapes.

Bibliography. Arendt & Tórrez (2009), Belcher & Smooker (1937), De Las Casas *et al.* (2004), Dornas *et al.* (2007), Gochfeld (1975), Haverschmidt (1970b), Haverschmidt & Mees (1994), Hilty (2003), Jaramillo & Burke (1999), Olmstead *et al.* (2011), Ramo & Busto (1981), Ridgely & Tudor (1989), Short (1968), Stiles & Skutch (1989), Wetmore *et al.* (1984).

105. **White-browed Blackbird**

Sturnella superciliaris



French: Sturnelle à sourcils blancs **German**: Weißbrauenstärling **Spanish**: Loica Cejiblanca
Other common names: Southern Marsh Meadowlark, Bonaparte's Blackbird

Taxonomy. *Trupialis superciliaris* Bonaparte, 1850, Mexico; error = Mato Grosso, Brazil.

Formerly placed with *S. militaris* in a separate genus, *Leistes*, but molecular data indicate close affinity with present genus. Closely related to, and may form a superspecies with, *S. militaris*; sometimes considered conspecific, but ranges overlap locally in SE Peru (E Madre de Dios), NE Bolivia (Pando and N Beni) and NE Brazil (NE Pará, Maranhão and N Tocantins) with no evidence of interbreeding, and no intermediates or hybrids between the two have been reported; range overlap sometimes attributed to seasonal N movements by present species, but verification required. Monotypic.

Distribution. SE Peru (Madre de Dios), E Bolivia (Beni) and C & E Brazil (S from Mato Grosso, and from NE Pará, Maranhão and Ceará) S to Paraguay, Argentina (S to Mendoza, La Pampa and Río Negro) and Uruguay.

Descriptive notes. Male average 17·8 cm, 50·2 g; female average 17 cm, 40·9 g. Male has mostly black head and upperparts, with prominent white superciliary line behind eye; chin, throat and breast bright crimson-red, marginal and most of lesser upperwing-coverts and marginal underwing-coverts red, belly and vent black; when freshly moulted (non-breeding plumage), black feathers have buff edges (giving striped appearance) and red breast feathers are tipped buff (barred appearance); iris brown; bill black, grey base of lower mandible; legs dark grey. Female is streaked blackish and buff on head and upperparts, with pale buff supercilium and median crownstripe,

some red in marginal upperwing-coverts; underparts buff, palest on throat, streaked dusky brown on breast, flanks and vent, centre of underparts tinged with pink; in fresh plumage (non-breeding), more boldly patterned, with broader buff edgings, pink area below obscured by brownish feather tips; bill horn-coloured to pinkish-flesh, usually greyer or duskier on upper mandible. Juvenile resembles female, but more extensively streaked below, no hint of red in plumage. Voice. Male song, from perch or in flight display, a nasal buzz preceded and followed by shorter notes, "tsi-tziéé-teng chup chup...", with some individual variation. Female may produce a dry rattle. Contact call (Argentina) a metallic "peng"; other described calls are "chuk" and harsh "pshee".

Habitat. Lush wet meadows and humid grasslands, nowadays particularly common in agricultural fields or pastures with wheat, oat, alfalfa (*Medicago*) and the like. In winter frequents wetlands and flooded grassland. Roosts in dense stands of grass. Mostly lowlands; reported at up to 2500 m in Bolivia (possibly as accidental).

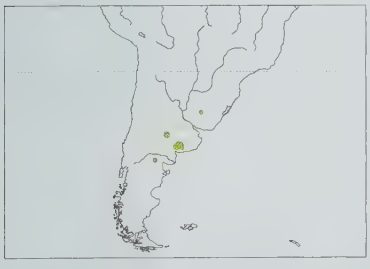
Food and Feeding. Mostly arthropods, also seeds. Insects and spiders (Araneae) comprised 75–85% of stomach contents in spring and summer in C Argentina. Insect remains include beetles (of families Curculionidae, Chrysomelidae, and scarabaeid subfamily Dynastinae), grasshoppers (Acrididae), stink bugs (Pentatomidae) and larvae of Lepidoptera; seeds mostly of wild grasses (*Panicum*, *Stipa*, *Lolium*), sedges (*Carex*) and weeds in family Asteraceae. In the Pantanal stomach contents include remains of small freshwater crabs (*Trichodactylus*). Forages on or near ground. Mostly in single-species flocks, reaching some hundreds of individuals; sometimes associates with other icterids.

Breeding. Season Oct–Jan in Argentina. Probably some males polygynous. Breeds solitarily or, more usually, in loose colonies; in Entre Ríos (Argentina) may nest near colonies of *Xanthopsar flavus*. Displaying male rises to 4–6 m and then descends, with red epaulets flared, in slow gliding flight while singing. Nest a deep cup of grass and other plant material, placed on ground among thick overhanging vegetation (mostly grass), sometimes a tunnel in surrounding vegetation leading to nest; site usually in pasture (natural or planted) or crop field, common crop plants used including wheat, alfalfa and oats. Clutch 3–5 eggs, pale blue, densely marked in reddish-brown, mean dimensions 23 × 17·3 mm; no information on incubation and nestling periods; chicks out of nest fed mostly by female. Parasitized by *Molothrus bonariensis*, and rears latter's chicks.

Movements. Probably resident in tropical and subtropical parts of range. Usually abandons nesting sites in agricultural fields soon after breeding; in austral winter found in wetlands over much of range in Argentina, roosting in patches of bunch-grass. Seasonal movements perhaps occur there during very dry or cold winters.

Status and Conservation. Not globally threatened. Rather common to locally uncommon. Extending its range in many areas as a result of deforestation and expansion of agriculture.

Bibliography. Belton (1985), Camperi, Cicchino & Darrieu (1998), Camperi, Ferretti *et al.* (2004), Di Giacomo (2005), Fraga (2002), Gochfeld (1979a), Jaramillo & Burke (1999), Narosky & Di Giacomo (1993), de la Peña (1987), Ridgely & Tudor (1989), Schubart *et al.* (1965), Short (1968), Tubaro (1992), Tubaro & Segura (1993), Zotta (1936).



106. Pampas Meadowlark

Sturnella defilippii

French: Sturnelle des pampas **German**: Schwarzschenkelstärling **Spanish**: Loica Pampeana
Other common names: Military Starling, Lesser (Red-breasted) Meadowlark, Red-breasted Meadowlark

Taxonomy. *Trupialis defilippii* Bonaparte, 1850, Montevideo, Uruguay.
Sometimes placed in a separate genus, *Pezites*, along with *S. bellicosa* and *S. loyca*; formerly treated as conspecific with both. In aspect and behaviour present species is almost a perfect intermediate between latter two species and the "red-breasted blackbirds" (*S. militaris* and *S. superciliaris*) formerly placed in *Leistes*. In the past was sometimes regarded as conspecific with *S. loyca*, but the two nest sympatrically and without interbreeding in parts of Argentina. Monotypic.

Distribution. N Uruguay (Salto Department) and CE Argentina (SW Buenos Aires, La Pampa and Río Negro).

Descriptive notes. Male average 21 cm, 73·6 g; female 67·5 g. Male has head and side of neck black, long white superciliary line becoming red in front of eye, white submoustachial stripe and lower eyelid; otherwise mostly dusky brown with brownish streaks above, uppertail-coverts barred, tail blackish with thin olive barring, marginal and a few lesser upperwing-coverts rosy red; chin to belly rosy red, side of breast, flanks and vent black, underwing-coverts black, with red marginal coverts; in fresh plumage (non-breeding) black areas above more prominently streaked brown, supercilium more buff, upperwing-coverts pale-tipped, red of underparts obscured by buff or olive feather tips; bill silver-grey, culmen and tip dark; legs dark brown. Differs from similar *S. loyca* in stockier build and shorter tail, less striped appearance, in flight also by black underwing-coverts. Female is paler and browner than male, with white throat, and streaked underparts enclosing pale pink-red lower breast. Juvenile is like female, but no red on underparts, and bill horn-coloured. Voice. Male flight song variable and rather musical, often combining ascending and descending whistles with a loud sustained note, e.g. "tse-tse-réé-tsew-tsee-tsew", last notes rather soft; perched song (from low above ground, mostly on bunch-grass) includes final buzzy or rasping notes, resembling those of *S. loyca*. Call "peet", also a rasping note.

Habitat. Native grasslands and pastures; only rarely in agricultural fields. Most individuals (82% of extant population) nest in natural grassland, the rest in agricultural fields; grasslands used for nesting in Argentina include *Baccharis* (Asteraceae) and grasses in genera *Stipa* and *Piptochaetium*. Uruguayan population breeds in native grassland mixed with carqueja (*Baccharis trimera*). Agricultural land abandoned for five years or more becomes increasingly suitable for nesting. Can live in treeless areas, and seldom perches on shrubs or fences. Lowlands to 900 m.

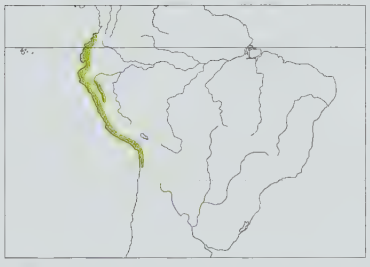
Food and Feeding. Insects and seeds. Contents of three stomachs included beetles (of families Scarabaeidae and Curculionidae) and seeds. Forages in small groups; in non-breeding season moves in flocks of some hundreds (formerly thousands, then compared to marching armies).

Breeding. Season Oct–Nov in Argentina. Mating system unstudied. Breeds in "reproductive groups" or dispersed colonies, nests more clumped than those of *S. loyca*; colonies contain 2–66 displaying males in Argentina, 3–25 in Uruguay. Male defends rather small territory, mean inter-nest distance in one study 23 cm. In flight display male flies upwards to c. 7 m, and then descends while singing. Nest a cup built from plant material, external diameter 9·5 cm, placed within depression on ground, near a grass clump, may have entrance corridor c. 8 cm long. Clutch 3–5 eggs, mean 3·14 eggs in recent study, variable, buff to grey with darker spots, blotches and lines, mean dimensions 25·8 × 18·3 mm; no information on incubation period; chicks fed mostly by female, nestling period c. 10 days; male possibly feeds fledglings. Parasitized by *Molothrus bonariensis*, but far less frequently than *S. loyca*; apparently female of this brood parasite find nests of present species hard to locate. Nesting success: in one study 29% of eggs produced fledglings.

Movements. The few reliable Brazilian records sometimes interpreted as representing seasonal movements; recent research on main population in Argentina suggests year-round resident. Further research needed.

Status and Conservation. VULNERABLE. Rare to locally uncommon. Nowadays found mostly around Sierra de la Ventana, a low (1200 m) range of rocky mountains in SW Buenos Aires, in Argentina; one population in N Uruguay. Formerly occurred in extreme SE Brazil (coastal Rio Grande do Sul), more widely in Uruguay, and in at least seven provinces in CE Argentina (S Cordoba, San Luis, E La Pampa, Corrientes, Santa Fe, Entre Ríos and Buenos Aires). Has declined considerably in range and numbers in both Argentina and Uruguay. In 1870s and 1890s flocks of many thousands reported in Buenos Aires *pampas*, particularly in territories recently taken from the native Indians; was still reported as a regular breeder throughout *pampas* up to early 1950s, but thereafter seriously declined. Main stronghold now SW Buenos Aires province, around Sierra de la Ventana and nearby ranges, where rocky soils do not favour ploughing and agriculture; recent surveys in this area have shown that population may approach 28,000 individuals. Uruguayan population much smaller, c. 200 individuals, and perhaps isolated. The possibility that similar isolated populations may be found elsewhere within its historical range merits investigation. Main cause of this species' rapid decline is replacement of natural grasslands with crops and planted pasture; interspecific competition with two sympatric meadowlarks (*S. superciliaris* and *S. loyca*) may also play a role. Capture for trade appears not to be an extensive problem, although, in 1988, more than 100 individuals of this species were seen in local markets. Breeding areas of this species mostly unprotected, but a few may be found in provincial reserves.

Bibliography. Anon. (2010d), Antoniazzi (2007), Aravena (1928), Azpiroz (1997, 2005), Belton (1985), Benites *et al.* (2007), Butchart & Stattersfield (2004), Cozzani *et al.* (2004), Doering & Lorentz (1939), Fraga (2007), Gabelli *et al.* (2004), Gochfeld (1975, 1978, 1979a, 1979b), Hudson (1920), Jaramillo & Burke (1999), Ridgely & Tudor (1989), Runnacles (1933–1940), Short (1968), Stattersfield & Capper (2000), Tubaro & Gabelli (1999), Zalba *et al.* (2009).



107. Peruvian Meadowlark

Sturnella bellicosa

French: Sturnelle du Pérou **German**: Weißschenkelstärling **Spanish**: Loica Peruana
Other common names: Greater Red-breasted/Peruvian Red-breasted Meadowlark, White-thighed Meadowlark

Taxonomy. *Sturnella bellicosa* De Filippi, 1847, Lima, Peru.
Sometimes placed in a separate genus, *Pezites*, along with *S. defilippii* and *S. loyca*; formerly treated as conspecific with latter or both. Two subspecies recognized.

Subspecies and Distribution.
S. b. bellicosa De Filippi, 1847 – SW Colombia (Nariño) and W Ecuador S to C Peru.
S. b. albipes (R. A. Philippi [Krumwiede] & Landbeck, 1861) – SW Peru S along Pacific slope of Andes to extreme N Chile.

Descriptive notes. Male average 20·5 cm, 78·5 g; female average 61·4 g. Male nominate race is mostly greyish-brown with blackish streaks above, head and side of neck blackish; long superciliary line, red in front of eye and white behind, short white submoustachial stripe and white lower eyelid; marginal and a few lesser upperwing-coverts red; chin to breast bright red, surrounded by blackish, belly black, flanks and undertail-coverts striped buffish-grey and blackish; underwing-coverts pale greyish-white, with red marginal coverts; iris dark brown; bill bluish-ivory, culmen and tip blackish-brown; legs grey-brown to blackish. Differs from similar *S. loyca* in smaller size and shorter tail and bill. Female is paler and more dusky than male, with buffy-white supercilium lacking red; underparts pale grey, throat whitish, central abdomen tinged pale red, breast and flanks to vent streaked dusky. Juvenile is like female, but lacks reddish tinges and more extensively streaked below. Race *albipes* is very like nominate, but smaller and less red. Voice. Male flight song complex and variable, not very musical, ending in buzzy note, the whole lasting c. 3 seconds; song from perch much shorter, consisting of 3–4 descending notes followed by harsh buzz, "tee-tleptu-chzzz". Call is a buzzing note.

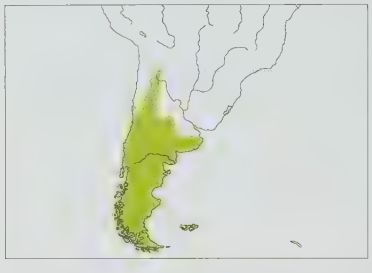
Habitat. Meadows, grassland and agricultural land; in coastal deserts found at oases or in irrigated fields, sometimes in brackish marshes with *Salicornia*. Nominate race to 2500 m.

Food and Feeding. Rather scant information. Diet presumably mostly arthropods, small vertebrates, seeds and some fruit. One stomach from Ecuador contained only seeds. Forages mostly on ground.

Breeding. Season Mar–May in Ecuador and Oct–Nov in Chile. Mating system not known. Male has short up-and down flight display accompanied by song. Nest made from dry grass and stems, with no obvious lining material, some substantial and often covered with dome, other nests reported as flimsy; built on ground, commonly using a slight depression, and placed under cover of small shrub or grass tuft. Clutch 4–5 eggs in Ecuador, 3–4 in Chile, buff, pinkish or creamy white, spotted, blotched and smeared with reddish-brown and lavender, sometimes with blackish scrawls, mean dimensions 25·4 × 18·5 mm; incubation period 14 days, nestling period c. 12 days; no further details. Parasitized by *Molothrus bonariensis*.

Movements. Apparently resident. Altitudinal movements probable in highlands.

Status and Conservation. Not globally threatened. Reasonably common. Has recently expanded its distribution following conversion of woodlands into pasture.



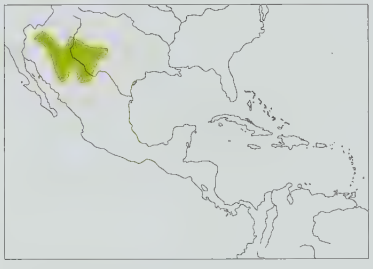
Bibliography. De Las Casas *et al.* (2004), Gochfeld (1975), Johnson & Goodall (1967), Marchant (1960), Olmstead *et al.* (2011), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989), Schulenberg *et al.* (2010), Short (1968).

108. Long-tailed Meadowlark

Sturnella loyca

French: Sturnelle australe **German**: Langschwanzstärling **Spanish**: Loica Común
Other common names: Red-breasted Starling, Greater Red-breasted Meadowlark

Taxonomy. *Sturnus loyca* Molina, 1782, Chile.
Sometimes placed in a separate genus, *Pezites*, along with *S. defilippii* and *S. bellicosa*; formerly treated as conspecific with latter or both. Birds intermediate between nominate race and *catamarcana* said to occur in W Argentina, and range listed for latter below is tentative; more detailed study required. Geographical variation partly clinal; size appears to increase from N towards S and in Andean highlands. If present species and *S. militaris* [= *Emberiza militaris* Linnaeus, 1758] are treated in separate genera, present species reverts to its older specific epithet, *militaris* [= *Sturnus militaris* Linnaeus, 1771], which has priority over *loyca*; as a result, present species has in some works been known as *Sturnella militaris*. Four subspecies recognized.
Subspecies and Distribution.
S. l. catamarcana (Zotta, 1937) – local in highlands of NW Argentina (Jujuy and Salta S to La Rioja).
S. l. loyca (Molina, 1782) – Chile (S Atacama S to Cape Horn) and Argentina (San Juan, San Luis, Córdoba and Buenos Aires S to Tierra del Fuego).
S. l. obscura Nores & Yzurieta, 1979 – Sierras de Córdoba and San Luis, in C Argentina.
S. l. falklandica (Leverkühn, 1889) – Falkland Is.



Descriptive notes. Male average 26·9 cm, 112·4 g; female average 97·1 g. Male nominate race is mostly brown with blackish streaks above, head and side of neck blackish; long superciliary line red in front of eye and white posteriorly, white submoustachial stripe and lower eyelid; marginal wing-coverts rosy red; chin to throat and underparts rosy red surrounded by blackish, belly black, side of breast to flanks and undertail-coverts striped buffish and black; underwing-coverts pale greyish-white; iris dark brown; bill bluish-ivory, culmen and tip blackish-brown; legs grey-brown. Differs from similar *S. defilippii* in larger size, longer tail and bill, pale underwing-coverts. Female is paler than male, with white throat, no red in superciliary; underparts with much heavy streaking surrounding pale red lower belly. Juvenile resembles female, but red below reduced, often just a pale pink patch, also bill paler. Race *catamarcana* is paler than nominate; *obscura* is darker than nominate, with red below restricted more to upper belly; *falklandica* has longer bill than nominate, bill slightly wide at tip ("spatulate"), also some white on outermost tail feathers. Voice. Song, by both sexes, usually from perch (e.g. shrub, rock, fence post), male rarely while flying, quite variable in different areas (possibly dialects): some populations produce whistles or warbles followed by long nasal buzz; others sing phrases of up to 8 notes, usually mixing some harsh buzzes; songs of race *catamarcana* may have reduced pitch range (1·5–5 kHz). Breeding partners may duet. Calls "peet" and "chuck".
Habitat. Mesic to dry grasslands and shrubby steppes of various types. In drier Andes partial to relatively wet grasslands (*vegas*) along watercourses or near marshes, often with clumps of pampas grass (*Cortaderia selloana*), also irrigated fields; in more humid highlands of Córdoba and San Luis (Argentina) found in rocky grasslands of *Festuca* and *Stipa*, also steppes of the resinous romerillo shrub (*Heterothalamus alienus*). Along Atlantic coast of Buenos Aires lives in bunchgrass formation of humid depressions near coastal dunes. In Patagonia in the most mesic or humid shrubby steppe, reaching edge (and clearings) of southern beech (*Nothofagus*) forest. In Falklands found in whitegrass (*Cortaderia pilosa*) fields, also near settlements. Is nowadays seen in agricultural fields (wheat) and planted pastures. Nominate race recorded from sea-level up to 2800 m; race *catamarcana* occurs at 1200–3100 m, sometimes up to 3500 m; race *obscura* breeds above 1100 m.
Food and Feeding. Arthropods (mostly insects), seeds and some fruit (*Berberis*). Feeds on maize (*Zea mays*) seeds in W Argentina. In Falkland Is said to feed on planted potatoes by probing and possibly gaping through the top soil. Forages mostly on ground and in low vegetation. Often turns pieces of dung or debris to find hidden prey. Perches in shrubs, on rocks and in small trees, also on poles and fence posts. Commonly forages in groups; during austral winter sometimes in flocks of up to 100 individuals.
Breeding. Season Sept–Jan in Chile and Argentina; nesting sometimes starts in late Aug in Falkland Is. Probably monogamous. Solitary breeder, nesting in pairs; pairs rather scattered and territorial in Sierra de San Luis (race *obscura*). Nest built by female, a cup of plant material, mostly grass stems, sometimes with partial dome-shaped roof, external dimensions quite variable, two nests from Argentina have inner diameter 8–11 cm and internal depth 5·5–9 cm, built within depression on ground among dense vegetation, quite well hidden and difficult to find, sometimes a tunnel leading through vegetation to nest; nests in Falklands nest may be up to 1 m above ground in clump of the tussock grass *Poa flabellata*. Clutch 3–4 eggs, buff to grey, densely marked with darker spots, blotches and lines, mean dimensions 28·6 × 20·6 mm (nominate race), 30·3 × 21·1 mm (*falklandica*), eggs laid at daily intervals; incubation by female, male may guard nest, both sexes feed chicks; no information on duration of incubation and nestling periods; family group persists for some months. Nests parasitized by *Molothrus bonariensis* in Argentina.
Movements. Apparently resident, even in extreme S (Tierra del Fuego). Some latitudinal and altitudinal movements in non-breeding season; in Los Glaciares National Park (Argentina) many individuals leave the area during severe winters. Race *falklandica* recorded as accidental on South Georgia.
Status and Conservation. Not globally threatened. Common and reasonably widespread; more local in drier Andes. Has expanded its range in C Argentina because of replacement of native woodland with pastures and irrigated agriculture; nominate race now found in Argentinian lowlands of Córdoba and San Luis, but this may be due to recent expansion. Population in Falkland Is (race *falklandica*) estimated at 6000–10,000 individuals in 1983–1993.

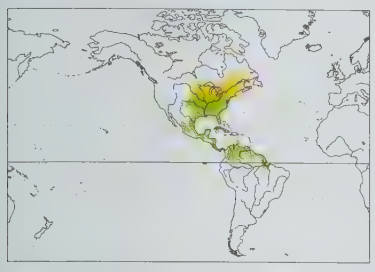
109. Lilian's Meadowlark

Sturnella lilianae

French: Sturnelle de Lilian **German**: Lilianstärling **Spanish**: Pradero de Lilian

Taxonomy. *Sturnella magna lilianae* Oberholser, 1930, Huachuca Mountains, Arizona, USA.
Thought to form a superspecies with *S. magna*, the two being geographically separated by distributional gaps. Previously treated as conspecific with *S. magna*, but differs vocally and morphologically; also, recent DNA data from mitochondria and the sex-linked Z chromosome revealed a deep genetic divergence, supporting treatment as two distinct species. Some races currently included in *S. magna* (notably *auropectoralis*) may belong with present species. Detailed genetic and morphological analysis of all Mexican breeding populations needed. Treated as monotypic.
Distribution. S USA (from C Arizona, C New Mexico and W Texas) S to N Mexico (S to N Sonora and C Chihuahua).

Descriptive notes. c. 20–22 cm; male average 112·4 g, female average 90·3 g. A stocky, long-billed icterid with relatively short tail. Male has crown blackish with pale buff to white central stripe, long supercilium mostly pale buffish, but yellow in front of eye, ear-coverts whitish, dark eyestripe behind eye; upperparts and upperwing striped blackish and buff; tail with central feathers barred, outer three or four pairs of rectrices entirely white (visible in flight); chin to belly golden-yellow, V-shaped black breastband, dark-streaked buffish flanks and lower belly; iris brown; bill grey, darker culmen and tip; legs greyish-pink. Differs from *S. magna* mainly in shorter tail with distinctive pattern (outer four rectrices almost entirely white). Female is similar to male, but duller in colour. Juvenile resembles adult, but neat pale feather fringes above (scaly-looking), duller yellow below, breastband replaced with black streaks. Voice. Song 4–7 plaintive whistled notes. Call a harsh "dzzht".
Habitat. Grasslands, and grasslands with mesquite (*Prosopis*), in desertic areas. Prefers drier areas than those occupied by *S. magna*. Reported as breeding mostly in highlands, from 1070 m up to 2750 m.
Food and Feeding. Few data. Diet presumably insects and seeds. Forages on ground, sometimes in small flocks.
Breeding. Season Apr–Jun. Mating system not known. Nest made from dry grass or dry stems, with dome-shaped cover, hidden in dense dry grass or weed clump, sometimes in depression in soil, in desertic grassland. Clutch 4–5 eggs, white to greyish-white, variably speckled and blotched in shades of brown, mean dimensions 28 × 20·5 mm; no information available on incubation and nestling periods.
Movements. Little information; sight identification of wintering meadowlarks may not be reliable. Altitudinal movements likely in Arizona. Further research needed.
Status and Conservation. Not assessed. Has reasonably large breeding range, and the species was rated as abundant in Arizona in 2005. Further research required.
Bibliography. Barker *et al.* (2008b), Barlow *et al.* (1994), Bent (1958), Bock *et al.* (1986), Corado (2008), Corman (2005), Herbert *et al.* (2004), Howell & Webb (1995), Jaramillo & Burke (1999), Lanyon (1962), Ligon (1961), McCarthy (2006), Navarro-Sigüenza & Peterson (2004), Phillips *et al.* (1964), Rohwer (1972a, 1972b, 1972c, 1976).



110. Eastern Meadowlark

Sturnella magna

French: Sturnelle des prés **German**: Lerchenstärling **Spanish**: Pradero Oriental
Other common names: Cuban Meadowlark (*hippocrepis*)

Taxonomy. *A.*[*lauda*] *magna* Linnaeus, 1758, South Carolina, USA.
Thought to form a superspecies with *S. lilianae*, the two being geographically separated by distributional gaps; previously treated as conspecific, but they differ vocally and morphologically, and recent DNA data from mitochondria and the sex-linked Z chromosome revealed a deep genetic divergence, supporting treatment as two distinct species; some races currently placed in present species (notably *auropectoralis*) may belong instead in *S. lilianae*. Present species is also closely related to *S. neglecta*. Race *hippocrepis* may merit full species rank. Subspecific limits, particularly in South America, need further study, e.g. race *monticola* commonly subsumed into *praticola*; distributions listed below are tentative. Populations in French Guiana and NE Brazil (Amapá) sometimes treated as race *quinta*, but type specimen of latter is from Roraima (N Brazil), technically within range of *monticola* (or *praticola*); these three taxa require re-evaluation. Race *inexspectata* has often been listed as "*inexpectata*" but this is an unjustified emendation. Fifteen subspecies currently recognized.
Subspecies and Distribution.
S. m. magna (Linnaeus, 1758) – breeds SE Canada (S Ontario E to New Brunswick) and E USA from Minnesota E to Maine S to C Texas and C North Carolina.
S. m. argutula Bangs, 1899 – S USA from Kansas and Oklahoma E to South Carolina and S to E Texas and Florida.
S. m. hoopesi Stone, 1897 – extreme S USA (SE Texas) and NE Mexico (N Tamaulipas).
S. m. auropectoralis G. B. Saunders, 1934 – highlands of W Mexico from Sinaloa S to upper R Lerma drainage (in México) and to coastal Nayarit.
S. m. mexicana P. L. Sclater, 1861 – coastal lowlands of E Mexico (from N Veracruz) S to Guatemala (Petén) and Belize.
S. m. griscomi Van Tyne & Trautman, 1941 – coast of N Yucatán, in SE Mexico.
S. m. hippocrepis (Wagler, 1832) – Cuba, including I of Pines.
S. m. saundersi Dickerman & A. R. Phillips, 1970 – Pacific lowlands of S Mexico (SE Oaxaca).
S. m. inexspectata Ridgway, 1888 – Honduras and adjacent NE Nicaragua.
S. m. alticola Nelson, 1900 – highlands from S Mexico (Chiapas) S to Costa Rica.
S. m. subulata Griscom, 1934 – Panama (mostly along Pacific slope).
S. m. meridionalis P. L. Sclater, 1861 – NE Andes from Colombia (Santander and Cundinamarca) E to NW Venezuela (Trujillo).
S. m. paralios Bangs, 1901 – N Colombia (Santa Marta Mts S to W base of E Andes) and savannas of N & C Venezuela.
S. m. praticola C. Chubb, 1921 – E *llanos* of Colombia and SE Venezuela E to Guyana and Suriname.

S. m. monticola C. Chubb, 1921 – Guianan highlands from Venezuela (Bolívar) and Guyana E to French Guiana and extreme N Brazil (Roraima and Amapá).

Descriptive notes. 20–24 cm; male average 102 g and female 76 g (*argutula*), male 86–110 g and female 65·6–88·7 g (*alticola*). A stocky, long-billed icterid. Male nominate race has crown blackish with pale buff to white median stripe, long supercilium dull whitish-buff, but yellow in front of eye, ear-coverts pale grey-brown, blackish eyestripe behind eye, whitish malar stripe; upperparts and upperwing striped blackish and buff; tail with central feathers barred, outer three rectrices largely white (visible in flight); chin to belly yellow, V-shaped black breastband, dark-streaked buffy flanks and lower belly; iris dark brown; bill grey, darker culmen and tip; legs light pinkish-flesh to greyish. Female is similar to male, but duller in colour. Juvenile is similar to adult, but paler, with more prominent pale fringes above (looking scaly), throat and underparts paler, black breastband replaced with dark streaking. Race *argutula* is smaller than nominate and has deeper yellow underparts; *hippocrepis* resembles previous, but much smaller, and more conspicuously streaked below; *mexicana* is characterized by more rufescent upperparts, and narrower pectoral band; *griscomi* resembles last, but larger and paler; *inexspectata* is smallest race in body weight and measurements, also darker than nearby *mexicana*, and white in tail more restricted; *hoopesi* is paler above than nominate, the rich brown tinges in upperparts and wing replaced by greyish-brown, blackish bars on wing and tail more distinct; *auropectoralis* closely resembles previous, but darker above and deeper orange-yellow below, shorter wing, tail has completely white outer rectrix; *saundersi* is like last, but with shorter wing and bill; *alticola* is medium-sized, with shorter wing and longer legs, has more greyish-brown upperparts than previous; *subulata* resembles *inexspectata*, but more white in tail; *meridionalis* has longest bill, is also larger and darker than neighbouring races; *paralios* resembles preceding race, but smaller and paler, with more white in tail; *praticola* is smaller and paler than last, with less white in tail; *monticola* differs from last in being slightly larger and darker. Voice. Song variable, usually a series of 4 pleasant, descending whistles. Female commonly produces a chatter, possibly equivalent to male song. Common call a sharp "dzert" or "jerzik"; also has loud rattle as alarm, also "weet" flight call.

Habitat. Open humid grasslands, meadows, alfalfa (*Medicago*) fields, hay fields, and pastures in general, with some variations within its huge range; less often in cultivated fields. Reported from open pine (*Pinus*) savannas, grassy marshes, agricultural land, weedy fields, and in South American *páramos*. Roosts primarily in thick grass. Up to 4100 m in C Mexico; 1700–3500 m in Andes (*meridionalis*).

Food and Feeding. Contents of 1514 stomachs comprised 74% animal food and 26% plant food. Feeds mostly on adult and larval insects, main insect prey consisting of crickets and grasshoppers (Orthoptera), also many Lepidoptera and beetles (Coleoptera); also takes invertebrates such as spiders (Araneae) and earthworms (Oligochaeta). A few stomachs contained lizards. Feeds on carrion of small roadkill mammals and birds. Eats wild and cultivated seeds, rarely fruits. Forages on ground. In non-breeding season found in flocks of up to c. 200 individuals, often mixed with *S. neglecta*.

Breeding. Season Apr–Aug in USA, Jan–Jul in Cuba, and from late Apr in Nicaragua; second broods frequent. In North America monogamous to moderately polygynous, with 1–3 females per male. Breeds solitarily. Male defends multi-purpose territory (feeding and mating), territories in Wisconsin (N USA) 1·2–6·1 ha; male also defends territory from sympatric male *S. neglecta*. Nest built by female, materials coarse dried grasses, stems, even bark, attached to nearby plants, lining of fine grass, external diameter 14–21 cm, internal diameter 8–15 cm, most nests partially covered with a dome, built on ground, sometimes in shallow depression, and well concealed by vegetation, many have entrance tunnel up to 1 m long; nests in C prairies of USA usually oriented against prevailing winds. Clutch 3–7 eggs, usually 4 in Cuba, white, spotted, blotched and speckled over entire surface in shades of brown and lavender, mean dimensions 27·8 × 20·4 mm; incubation by female, period 13–14 days; chicks fed by female, only minor contribution by male, nestling period 10–12 days; post-fledging parental care lasts c. 2 weeks. Nests parasitized by *Molothrus ater*.

Movements. Usually resident in Cuba and in Central and South America. Populations from Canada S to N Mexico migratory, but seasonal status and winter ranges of Mexican populations require more study; sight identification of wintering meadowlarks may not be reliable. Leaves breeding grounds in N of range in Sept–Oct; returns to Canada and N USA from Mar, earlier (late Feb) in S USA.

Status and Conservation. Not globally threatened. Common and widely distributed in N portion of range; fairly common to locally common in Mexico and in Central and South America. Records of race *auropectoralis* in coastal Nayarit (W Mexico) possibly involve migrants, rather than breeding individuals. Some of the C & S populations may be of conservation concern, e.g. Cuban race *hippocrepis*, especially in view of its possible status as a distinct species; further study required.

111. Western Meadowlark

Sturnella neglecta

French: Sturnelle de l'Ouest **German**: Wiesenstärling **Spanish**: Pradero Occidental

Taxonomy. *Sturnella neglecta* Audubon, 1844, near Fort Croghan, North Dakota, USA.
Closely related to *S. magna*. Monotypic.

Distribution. Breeds in Canada (from S British Columbia and NC Alberta E to SW Ontario) and S in W USA (E to Michigan, W Iowa and W Texas) to Mexico (S to N Baja California, Sonora and C plateau in Guanajuato); in winter extends farther S into Mexico and E in USA to R Mississippi and the Gulf Coast.

Descriptive notes. Male average 21 cm, 106 g; female average 19 cm, 89·4 g. A stocky, long-billed icterid. Male has blackish crown with pale buff to white median stripe, long supercilium mostly dull whitish-buff, but yellow in front of eye, ear-coverts usually smudged brownish or striped blackish, dark eyestripe behind eye; upperparts and upperwing striped blackish and buff; tail brown, central feathers thinly barred dark, outer three pairs white with dark shaft streak (visible in flight); malar region (and sometimes submoustachial area) and chin to belly yellow, V-shaped black breastband, buffy flanks and lower belly with darker streaks; iris dark brown; bill grey-blue, darker culmen and tip; legs light flesh-coloured. Differs from similar *S. magna* mainly in paler coloration, yellow malar. Female is similar to male, but duller in colour. Juvenile is paler than adult, particularly in yellow areas of plumage, and has breastband replaced with dark streaking; bill pinkish, tipped dark. Voice. Song of male lasts c. 1·5 seconds, consists of 1–6 rather pure whistles followed by 1–5 gurgling notes. Also a flight song, a jumbled series of notes. Calls include "chuck" and a rattle or chatter.

Habitat. Pastures, meadows, hay fields, less often in cultivated fields. Where range overlap with *S. magna*, present species usually in drier grasslands; when overlapping with *S. lilianae*, occupies more humid habitats. Roosts in dense grassland. Breeds at up to 2200 m.

Food and Feeding. Stomach contents 70% animal food, 30% plant food. Insects commonly represented included weevils (Curculionidae), crickets and grasshoppers (Orthoptera), caterpillars of Lepidoptera, and ants (Formicidae). Reported as feeding on eggs of Mormon crickets (*Anabrus simplex*). Feeds on carrion of roadkilled vertebrates. Plant food mostly seeds; weed seeds predominate in autumn, cultivated seeds in winter. Rarely feeds on fruits. Forages on ground. Forms flocks of up to c. 200 individuals in non-breeding season.

Breeding. Season Apr–Aug in USA; second broods frequent. Monogamous to moderately polygynous, with two or three females per male. Male defends multi-purpose territory (feeding, mating), even against male *S. magna*; territory size in Iowa (USA) 3–14 ha. Nest built by female, from coarse dried grasses, stems and bark, lined with fine grass, partially covered with a dome, placed on ground, sometimes in shallow depression, well concealed by vegetation, and usually with entrance tunnel. Clutch 3–7 eggs, white, spotted, blotched and speckled over entire surface in shades of brown and lavender, mean dimensions 28·1 mm × 20·6 mm; incubation by female, period 13–14 days; chicks fed by female, with variable contribution by male, nestling period 10–12 days; post-fledging parental care c. 2 weeks. Nests parasitized by *Molothrus ater*.

Movements. Medium-distance migrant, with overlapping breeding and non-breeding ranges. Winters from extreme SW Canada across much of US breeding range, but extending farther E in S USA and reaching Gulf Coast; also into most of N & C Mexico S to S Baja Califonia, Michoacán and S Tamaulipas. Also performs altitudinal movements in highlands. Recorded from Guadalupe I (off W Baja California) in Mar. Vagrant in Alaska.

Status and Conservation. Not globally threatened. Common to abundant in much of its extensive range. In North America seems to be a more numerous species than *S. magna*.

Temminck (1823). *Planches Color.*, Livr. **41**: plate 243 and text [*Stephanophorus diadematus*].

Temminck (1824). *Planches Color.*, Livr. **49**: plate 293, fig. 2 and text [*Conirostrum speciosum*].
Temminck (1836). *Planches Color.*, Livr. **98**: plate 580 and text [*Emberiza spodocephala personata*], plate 583, fig. 1 and text [*Emberiza elegans*], plate 583, fig. 2 and text [*Emberiza variabilis*].
Temminck & Schlegel (1848). In: Siebold, *Fauna Jap., Aves*, Part **4–8**: 100, plate 60 [*Emberiza sulphurata*].
Thayer & Bangs (1905). *Bull. Mus. Comp. Zool. Harvard* **46**: 96 [*Cyanerpes cyaneus gigas*], 97 [*Coereba flaveola gorgonae*].
Thunberg (1822). *Mém. Acad. Imp. Sci. St. Pétersbourg* **Ser. 1, no. 8**: 284, plate 8, fig. 1 [*Chlorophonia cyanea*].
Todd (1912). *Ann. Carnegie Mus.* **8**: 198 [*Arremonops tocuyensis*], 200 [*Tiaris obscurus haplochroma*], 201 [*Saltator orenocensis rufescens*], 202 [*Tangara guttata eusticta*], 203 [*Tangara guttata trinitatis*, *Schistochlamys melanopis aterrima*].
Todd (1913). *Proc. Biol. Soc. Washington* **26**: 169 [*Catamenia homochroa oreophila*].
Todd (1915). *Proc. Biol. Soc. Washington* **28**: 79 [*Sporophila hypochroma*, *Zonotrichia capensis hypoleuca*].
Todd (1916). *Ann. Carnegie Mus.* **10(1/2)**: erratum opp. 276 [*Quiscalus niger caribaeus*].
Todd (1916). *Proc. Biol. Soc. Washington* **29**: 95 [*Nemosia pileata hypoleuca*].
Todd (1917). *Proc. Biol. Soc. Washington* **30**: 3 [*Psarocolius decumanus melanterus*], 4 [*Icterus mesomelas carrikeri*], 128 [*Diglossa caerulescens saturata*, *Thlypopsis fulviceps intensa*, *Tachyphonus luctuosus panamensis*, *Thraupis cyanocephala hypophaea*].
Todd (1919). *Proc. Biol. Soc. Washington* **32**: 113 [*Atlapetes semirufus majusculus*, *Habia rubica coccinea*].
Todd (1922). *Condor* **24**: 126 [*Aimophila ruficeps canescens*].
Todd (1922). *Proc. Biol. Soc. Washington* **35**: 89 [*Poospiza torquata pectoralis*], 90 [*Arremon aurantiirostris strictocollaris*, *Sicalis luteola flavissima*, *Sporophila americana dispar*], 91 [*Saltator grossus saturatus*], 92 [*Piranga flava rosacea*, *Tangara cayana fulvescens*, *Thraupis palmarum atripennis*], 93 [*Chlorospingus canigularis conspicillatus*, *Mitrospingus cassinii costaricensis*].
Todd (1923). *Auk* **40**: 61 [*Cyanocompsa cyanoides caerulescens*].
Todd (1923). *Proc. Biol. Soc. Washington* **36**: 38 [*Arremonops conirostris umbrinus*].
Todd (1924). *Auk* **41**: 147 [*Melospiza melodia atlantica*].
Todd (1924). *Proc. Biol. Soc. Washington* **37**: 122 [*Chlorophanes spiza subtropicalis*, *Conirostrum leucogenys cyanochroum*, *Icterus croconotus strictifrons*].
Todd (1932). *Proc. Biol. Soc. Washington* **45**: 218 [*Conirostrum albifrons cyanonotum*], 219 [*Agelasticus thilius alticola*].
Todd (1938). *Auk* **55**: 117 [*Ammodramus nelsoni alter*].
Townsend, C.H. (1890). *Proc. US Natl. Mus.* **13(799)**: 136 [*Artemisiospiza belli cinerea*], 139 [*Melospiza melodia graminea*].
Townsend, C.H. (1923). *Bull. Amer. Mus. Nat. Hist.* **48**: 20 [*Pyrgisoma fuscum jamesi*].
Townsend, J.K. (1837). *J. Acad. Nat. Sci. Philadelphia* **7**: 188 [*Junco hyemalis oreganus*], 189 [*Calcarius ornatus*].
Traylor (1950). *Nat. Hist. Misc.* **64**: 1 [*Tangara cyanicollis albotibialis*].
Trudeau (1839). *J. Acad. Nat. Sci. Philadelphia* **8**: 160 [*Piranga leucoptera*].
Tschudi (1844). *Arch. Naturges.* **10(1)**: 284 [*Hemispingus frontalis*], 285 [*Tangara arthus pulchra*, *Tangara vassorii atrocoerulea*, *Tangara xanthocephala*], 286 [*Chlorochrysa calliparaea*], 287 [*Iridosornis analis*, *Piranga leucoptera ardens*], 288 [*Chlorornis riefferii elegans*], 289 [*Arremon brunneinucha frontalis*], 290 [*Haplospiza rustica*, *Phrygilus plebejus*], 294 [*Diglossa cyanea melanopis*].
Tschudi (1846). *Unters. Faun. Peru, Aves*: 216 [*Sicalis olivascens chloris*].
Underdown (1931). *Auk* **48**: 612 [*Chlorospingus ophthalmicus dwighti*].
Underwood (1898). *Bull. Brit. Orn. Club* **7(9)**: 59 [*Chlorospingus canigularis olivaceiceps*].
Valqui & Fjeldså (2002). *Ibis* **144**: 347 [*Atlapetes melanopsis*].
Van Tyne & Sutton (1937). *Misc. Publ. Univ. Mich. Mus. Zool.* **37**: 102 [*Pipilo maculatus gaigei*].
Van Tyne & Trautman (1941). *Occas. Pap. Mus. Zool. Univ. Mich.* **439**: 7 [*Sturnella magna griscomi*].
Van Tyne & Trautman (1946). *Occas. Pap. Mus. Zool. Univ. Mich.* **496**: 1 [*Agelaius phoeniceus pallidulus*].
Verreaux, J. (1852). *Rev. Mag. Zool.* **Ser. 2, no. 4**: 314 [*Sporophila peruviana devronis*].
Verreaux, J. (1869). *Nouv. Arch. Mus. Hist. Nat. Paris (Bull.)* **Ser. 1, no. 5**: 15, plate 1, fig. 1 [*Sporophila frontalis*].
Vieillot (1807). *Hist. Nat. Ois. Amér. Septentrionale* **1**: 4 [*Piranga*].
Vieillot (1809). *Hist. Nat. Ois. Amér. Septentrionale* **2** (1807): 32, plate 90 [*Conirostrum bicolor*], 70 [*Coereba*].
Vieillot (1816). *Analyse Nouv. Orn. Elément.*: 30 [*Passerina*], 32 [*Arremon*, *Nemosia*, *Pipilo*, *Saltator*], 33 [*Agelaius*, *Tachyphonus*], 34 [*Sturnella*], 36 [*Quiscalus*], 40 [*Cissopis*, *Lanio*].
Vieillot (1816). *Nouv. Dict. Hist. Nat.*, 2nd edition, **5**: 364 [*Procacicus solitarius*].
